ENCYCLOPÆDIA

EDINENSIS.

ENCYCLOPÆDIA EDINENSIS:

OR

DICTIONARY

OF

ARTS, SCIENCES, AND LITERATURE.

IN SIX VOLUMES,

INCLUDING ALL THE MODERN IMPROVEMENTS TO THE PRESENT TIME; AND ILLUSTRATED WITH UPWARDS OF ONE HUNDRED AND EIGHTY ENGRAVINGS.

KNOWLEDGE IS POWER.—Bacon.

VOLUME FIRST.

EDINBURGH:

PUBLISHED BY JOHN ANDERSON, JUN. 55, NORTH BRIDGE STREET, EDINBURGH; COWIE, LOW, & CO. LONDON; RICHARD BURDEKIN, YORK; AND WILLIAM CURRY, JUN. & CO. DUBLIN.

MDCCCXXVII.

PREFACE.

In announcing the completion of the Encyclopædia Edinensis, the Proprietor begs leave to assure the subscribers, that, in conducting this undertaking, it has uniformly been his study not only to fulfil, but even to exceed the expectations held out in the prospectus. He, therefore, feels much satisfaction in being enabled now to present to the public this work, embracing almost all the departments of human knowledge in a form so concise, and at the same time so complete, without transgressing the limits originally proposed. Although unavoidably deprived of the valuable co-operation of the original Editor, Dr. James Millar, he may still be permitted to congratulate the subscribers, that the arrangements he has effected, have been such as cannot fail to satisfy them, that the respectability of the Publication has been successfully supported, and that neither labour nor expense has been wanting on his part to bring it to a speedy and satisfactory termination. The public will now be enabled to form a proper estimate of its merits, not only regarding the selection of the materials, but also in respect to the quantity of matter contained in each volume, compared with that of any contemporary publication of the same kind. To such as are denied the advantage of public libraries, and of numerous and expensive publications, this work, which admits of being so easily carried about from one place or country to another, cannot fail to be extremely valuable, since it contains, within a narrow compass, the essence of all the information we possess respecting the different countries of the world, and not only delineates the boundaries and extent of every continent, state, and kingdom, on the globe, but also contains a distinct view of the political, moral, and commercial condition of each; thus furnishing a convenient register of knowledge, digested in an easy and agreeable form, and containing an immense variety of remarkable and valuable facts, which no memory can accurately retain, and which, were it not for such compositions, might occasion no small expense, and no little time and labour to investigate. The extended details and profound discussions, on abstruse subjects, which abound in most Encyclopædias, have justly been complained of, as unsuitable to a numerous class of readers; and the magnitude and great expense of such works, preclude not a few from the benefits which they are so eminently calculated to afford. From a persuasion, therefore, that many of the works of this nature are not only too expensive, but also too voluminous and inconvenient for general use, the Encyclopædia Edinensis was originally projected; and it will be found not only to obviate these inconveniences, but, from its moderate size, and the style of its execution, will be accommodated to a more extended circle of readers than any popular work of a similar description.

While the various treatises on the higher branches of science form a prominent feature in this Encyclopædia, the subjects of miscellaneous literature, and of history, both ancient and modern, occupy at the same time their adequate proportion, and, instead of indulging in extraneous speculations, the primary object uniformly kept in view, has been to promote useful knowledge, to mingle instruction with amusement, and to render the different branches of science perspicuous and intelligible to readers of every class. The accounts of the different empires, and the descriptions of the inferior districts or counties which they contain, have been entirely written anew. The larger treatises on scientific subjects have been drawn up with the greatest care by professional men of eminent talents, and have either been methodically arranged under different heads, with a running title, or furnished with a copious and accurate index, so as to render a more particular division superfluous. The political changes that have taken place in the various countries of the world, as well as the wonderful moral and scientific revolutions which have lately occurred, have also been brought under the review of the reader, while the discoveries and improvements recently made in all the branches of experimental philosophy, have been duly examined and discussed. That interesting and important branch of knowledge which records the lives of eminent men, particularly the biography of distinguished *literary characters*, will be found to be very complete, having been drawn from the most authentic sources, and brought down to the latest period of publication. The science of geography has been rendered particularly interesting by the Maps which accompany this treatise; and the public, it is hoped, will find that the great divisions of the earth, and of particular countries and states, have been *accurately delineated*. The drawings intended to illustrate the various subjects treated of, have also been executed with great taste and precision, and are elegantly engraved by the most eminent artists. In such a work as this, so diversified and extensive, mistakes, inaccuracies, and omissions, may naturally be expected, and all that the proprietor can venture to hope on this point is, that they are not very numerous, and perhaps fewer than will be found in most publications of a similar kind.

The Proprietor ought not to omit acknowledging his obligations to those friends and literary gentlemen, to whose inspection the treatises contained in it have been occasionally submitted, and some of whom have largely contributed to the merits of this undertaking, by the numerous original treatises they have furnished on various subjects. Among these he is proud to announce the names of the original editor, Dr. James Millar, Dr. Jeremiah Kirby, and Dr. Richard Poole of Edinburgh. The labours of these three principal contributors to this work have been so extensive, that, to enumerate them individually, would occupy a greater space than the limits of this Preface will allow. It may be sufficient to state, that Dr. Millar, besides his almost innumerable minor contributions, as editor of the first Eighteen Parts, has contributed most of the principal treatises in that division of the work, especially Bleaching, Botany, Chemistry, *Galvanism*, (under Electricity,) and Geology. Dr. Kirby, among his numerous contributions, has furnished the whole department of Medicine, except Midwifery, including Anatomy, Dietetics, Materia Medica, Medicine, *Human* and *Veterinary*, and Surgery; he has composed many of the principal Zoological Treatises, especially Bee, Entomology, Erpetology, Helminthology, and Ichthyology; some of the most important Geographical and Historical articles, as Geography, Hanover, New Holland, Ireland, Judæa, Russia, Sweden, Switzerland, and Turkey; several prominent treatises on some of the Chemical Arts, as Brewing, Dyeing, Fire-Works, and Glass Manufacture; and some treatises on Experimental Philosophy, particularly Electricity, Optics, and Pneumatics. Dr. Poole, in addition to other contributions, has furnished the treatises on Architecture, Education, Language, Mathematics, Mind, Philology, Philosophy, and Phrenology. It may be satisfactory to the reader also to learn, that the articles Astronomy and Dialling were compiled by George Buchanan, Esq. Civil Engineer, Edinburgh; Magnetism and Meteorology, by the Rev. Dr. Russel of Leith; Design, by Patrick Gibson, Esq. of the Dollar Institution; and Mechanics, by the Rev. David Liston, Calcutta; that the treatise on Midwifery was furnished by John Dick, M. D. Mid-Calder; and that on Music, by the Rev. Henry Liston of Ecclesmachen. Besides various geographical and historical contributions by the Rev. Thomas Nelson, and the Rev. Alexander Duncan, Mid-Calder, the former composed the treatise on Religion, and the latter the articles Miracle, Name, Necker, Prejudices, Pyramids, and Reformation. The history of the Polar Expeditions, and the Essay on Sports and Pastimes, together with numerous small contributions in volumes fifth and sixth, were furnished by Mr. Alexander Anderson; Theology, also America, South, in the Addenda, by Mr. Walter Tod; and Navigation, by Mr. William Galbraith, Teacher of Mathematics, Edinburgh. Among the other distinguished individuals to whom the proprietor is indebted for assistance in the execution of this work are, the Rev. James Couper, D. D. Professor of Practical Astronomy in the University of Glasgow, and Lockhart Muirhead, LL. D. Professor of Natural History, the latter of whom composed the treatises on Ophiology and Ornithology; also Robert Wallace, A. M. Professor of Mathematics of the Andersonian Institution in that city, who conducted, and who furnished the greater part of the contributions in the Addenda in volume sixth, and the Preliminary Dissertation in the first volume. In addition to these may be mentioned the names of the Rev. John Adamson of Newton; of Messrs. James Flint, Land-Surveyor, Robert Macmillan, John Wallace, Teacher of Mathematics, Edinburgh, and Alexander Peterkin, late Sheriff-substitute of Orkney; also that of the Rev. John Sommers, D. D. who superintended the publication of the last Twelve Parts of this work, and who, besides supplying a great variety of articles in the departments of Geography and Biography, not only contributed the treatises on Plant and Planting, Poor and Poor Laws, Railway, Road, Stipend, Teinds and Tithes, together with Antiquities, Prophecy, and Revenue, in the Addenda, but also furnished a considerable portion of the treatises on Mammalia, Missions, and Moral Philosophy. To his friends Sir William Hamilton, Bart. and his brother Thomas Hamilton, Esq. the proprietor has also been indebted for many useful suggestions and other occasional assistance in the execution of the work. Besides these, several other individuals of distinguished talents have contributed their literary labours and friendly assistance, but their names it is wholly unnecessary here to particularize. Most of the gentlemen above mentioned have been long known in the republic of letters, by their numerous and valuable contributions to the Britannica, the Edinburgh Encyclopædia, Metropolitana, and similar works of great literary merit. The publication of the fourth edition, and of the last 15 volumes of the fifth edition of the Encyclopædia Britannica, was conducted under the able superintendence of Dr. Millar, while Dr. Kirby, Dr. Poole, and Dr. Muirhead were likewise among the principal contributors to that valuable publication.

Encyclopædias of various kinds have now been long in use, and have been read and consulted with great avidity, both by the learned and unlearned, throughout the various nations of Europe. From the number and variety of these publications, one of which may be considered as constituting the library of many an individual who has neither much time nor much money to dispose of, the reader may be enabled to form a tolerably correct idea of the progressive improvement of the sciences and of literature, since as they approached the standard of real excellence and perfection, books of this kind seem to have multiplied in proportion. Most of these Encyclopædias will be found, on examination, to be only copies of such as have preceded them, with additions, corrections, and improvements, adapted to the state of the sciences at the period when they were published; and some of them, indeed, which profess not to be original, but mere compilations, will, on examination, be found to be the most correct, the best arranged, and the most valuable. By this means all repetitions and extraneous matter are excluded, which cannot possibly be the case with such as consist wholly of original essays and contributions, as every writer is apt, more or less, to touch upon kindred topics connected with the subject on which he writes.

At a very early period, Lexicons, Dictionaries, and other works similar to an Enclyclopædia, were published under different titles, some of which were excellent and valuable at the time, and evinced in the compilers, marks of great industry as well as a wonderful degree of useful information. Pliny's *Natural History* was esteemed a work of this kind, as it included all that the ancients comprehended under that head. Alfarabius, who is mentioned by Casiri as a celebrated Arabian writer of the tenth century, is said to have composed a work which treats of the liberal Arts and Sciences, to which he gave the title of Encyclopædia. Another curious publication of this kind is that of Scalichius *Paulus* de Lika.—*Encyclopædiæ, seu Orbis Disciplinurum, tam Sacrarum quam Prophanarum, Epistemon. Basileæ,* 1559, in quarto. In 1638, the title of Encyclopædia was likewise given to a Dictionary of the Arts and Sciences, published in two volumes, folio, by J. H. Alstedius, a German author of no inconsiderable talent and erudition. To this succeeded the "*Idea Encyclopediæ Mathematico-Philosophicae,*—Erhardi Weigelii, which was published in 1657. After this, in 1661, appeared "*Caspari Schotti Cursus Mathematicus, Libris* 28, *sive Encyclopædia omnium Disciplinarum Mathematicarum;*" and in 1668 the "*Lexicon Mathematicum*" of Vitalis. There was also published in 1573, a curious work similar to an Encyclopædia, which was reprinted at Strasburgh in 1579, under the title of "Lexicon, *seu Dictionarium Mathematicorum in quo Definitiones et Divisiones continentur Scientiarum Mathematicarum, Arithmeticae, Logisticae, Geometriae, Geodesiæ, Astronomiae, Harmoniae,—M. Conrado Dasypodio,* Auctore." In 1598, this was followed by the "*Tabula Artium et Professionum Mathematicarum,*—Lazari Schoneri." A work of very considerable merit was also published at Paris in 1690, under the title of *Dictionnaire Mathematique,* by Ozanam. In 1706, Dr. Harris gave to the world his *Lexicon Technicum,* or *Universal Dictionary of Arts and Sciences;* and in 1710, the second volume of that valuable production, to which was added a supplement, to bring down the improvements in the sciences to 1736, and before 1741 it had gone through five editions. For a long time this excellent work furnished materials for many succeeding compilations of the same kind. Subsequent to this appeared the "*Compendieuses Gelehrten-Lexicon,*" by H. D. John Burkhard Menken; the *Lexicon Mathematicum* by Wolfius; and the *Mathematical Dictionary* by Stone; followed by a host of inferior productions of a similar kind.

To these succeeded a work of very superior merit, the Cyclopædia of Chambers, in 2 vols. folio, first published in 1727, which greatly surpassed in style and execution all that had gone before it. In the short space of eighteen years this valuable work had seen no less than five editions; and it was rendered still more valuable by a large supplement of two additional volumes to another edition, all of which were embodied by Dr. Abraham Rees in 1786, in 4 vols. folio. This publication, by the united labours of Dr. Rees and Dr. Price, was rendered still more complete, and has within these few years been given to the world in a finished form, consisting of 40 volumes quarto, besides six volumes of splendid engravings.

A vast number of other productions of a similar nature, many of them of great celebrity, have, within the last century, been published in Germany and France. The most distinguished of these are Ludwig's "*Grosses Volstaendiges Universal Lexicon,*" published in 1732, in 68 volumes folio. The *Encyclopedié, ou Dictionnaire Raisonnée des Sciences des Arts et des Metiers,* of Diderot, D'Alembert, &c. 28 vols. folio, with a supplement of five additional volumes. This great work was begun in 1751, and completed in 1772, and the supplement, which was begun in 1776, was finished in 1778. The same work was also published at Geneva nearly at the same period, and also at Yverdun, in 58 quarto volumes; and a few years afterwards at Lausanne, in 39 volumes, royal octavo. Being again new-modelled at Paris, it was published under the title of *Encyclopedié Methodique,* by a society of literary gentlemen, in which the arts and sciences are included in separate treatises; so that this great undertaking comprehends not fewer than 40 separate Dictionaries; and when completed will exceed in magnitude any work of a similar kind, as nearly 150 vols. quarto, were completed before the French Revolution interrupted the publication.

Several other works under the title of Dictionaries and Encyclopædias also appeared about this time in Britain, such as Owen's New and Complete Dictionary of Arts and Sciences, which possesses no small degree of merit. It consists of 6 vols. octavo, and has gone through several editions since it was first published in 1754, and has furnished materials for various subsequent compilations. We may here also mention the Encyclopædias of Proctor, Croker, Clark, Castieau, Hall, Barrow, Howard, and Gregory; the British, English, London, Imperial, Domestic, Oxford, and Edinburgh Encyclopædias; the Portable, and the New Cyclopedias; the Pantalogia, the Perthensis, and the Metropolitana. To these may be added a great variety of particular Dictionaries on separate branches of science, such as the Medical Dictionaries of Quincy, James, Motherby, Parr; the Chemical Dictionaries of Nicholson, of Aikins, and of Macquer; Dictionaries on Law by Cunningham, Burn, and by Giles Jacob, improved by Tomlins; on Gardening, by Millar, Dickson, and Martyn; on Numismatology, by Guesseine and Rasch; the Marine Dictionaries of Falkoner and Chapman; Dictionary of Architecture by Felibien; Dictionaries of Music by Rousseau, Hoyle and Busby; Mortimer and Postlethwaite's Dictionaries of Trade and Commerce; Hutton's Mathematical and Philosophical Dictionary; and Barlow's excellent work of the same kind; Smith's Panorama of Science and Art; also his Mechanic, or Compendium of Practical Inventions; with smaller works of this kind almost without number.

But the most valuable Encyclopædia that has hitherto been completed in Britain, and one that eclipsed all that had gone before it, was the Britannica, first published in 3 vols. at Edinburgh, 1771. Several improved and enlarged editions of it soon afterwards appeared, and in 1800 it was again revised and extended to 20 vols. quarto, by a supplement of 2 vols. under the superintendence of Dr. Gleig. This masterly work has now passed through six editions, and has lately been greatly improved and enriched by a splendid supplement of 6 vols. making in all 26 vols. quarto. Two works of great merit, already noticed, are also in progress of publication, the Edinburgh Encyclopædia and the Metropolitana, which, when completed, will do honour to their conductors. The first of these follows the plan of the Britannica in the form of a Dictionary, and the latter, that of the French works, which include separate sciences or dictionaries under a philosophical and an alphabetical arrangement.

The prodigious number of Encyclopædias and Dictionaries of a similar nature that have been published during the last century, clearly proves that the public is extremely partial to works of this description; so that while the arts and sciences continue to improve, such literary productions may be expected to increase. Whether the present work will add to the value and respectability of such publications, remains for the subscribers and the public to determine.

Edinburgh, October, 1826.

HISTORICAL DISSERTATION

ON THE

ORIGIN AND PROGRESS OF THE ARTS AND SCIENCES.

THE origin of the Arts and Sciences is, like that of nations, involved in obscurity and fable. Knowledge began to dawn upon the human race in those genial climes that are first illuminated by the rising sun; and, like that luminary, though its early rays were comparatively feeble, yet they were, in the progress of civilization, gradually rendered more brilliant by the fire of superior genius, till they ultimately reached a state of meridian splendour. The useful arts which sprung up in the infancy of the world, are but slightly mentioned in Holy Writ, and of the antediluvian ages we have no other record. According to the traditions delivered by Josephus, the science of Astronomy was first cultivated by the sons of Seth, and the discoveries of those early observers of the heavenly bodies, were, for the benefit of posterity,

"On flood-surviving pillars deep enroll'd."

After the flood, many ages elapsed before Science assumed a consistent and systematic form. When mankind began to relinquish a wandering and savage life,—when the Nimrods of the primitive periods of society had ceased to hunt their fellows like beasts of prey,—when conventions were held, and general laws established for the common good,—and when, by universal consent, it was agreed that every one should provide for his own subsistence, without seizing on the property of another,—then, necessity, self-preservation, and domestic comfort, the great springs of physical exertion, gave rise to the most useful Arts. Houses were built, iron was forged, the land was divided, and the courses of the stars were observed. Nor is it remarkable that Astronomy should have been among the first of the Sciences; it was necessary even to Agriculture. The spontaneous productions of the earth were insufficient for the support of man approaching to civilization; useful plants and fruits required labour and cultivation to bring them to a state of perfection; and as the ground brought forth only at stated periods, it was necessary to regulate the operations of agriculture by the seasons of the year. The observations for these purposes, at first rude and unskilful, were connected with Science by a secret tie, though for many ages, experience and custom were the only guides.

At length arose some aspiring genius, who, collecting the traditionary knowledge, observations, and aphorisms of earlier times, formed them into a system, ill-arranged, perhaps, and incongruous at first, but sufficient to point out to mankind the progress of knowledge, and its immense advantages to society. The magnificent spectacle which the vast field of nature presented to the senses and imagination of man, was then beheld with new feelings of delight; he learned to examine the parts of which it was composed and to compare them with each other; his powers were increased and his condition ameliorated by the process; ideas acquired from physical objects were transported into an intellectual world; the phenomena of nature were studied with a discriminating attention, and desires were excited in the mind to ascertain the causes by which they were produced. The fine feeling expressed in that line of the Roman poet,

"Felix qui potuit rerum cognoscere causas,"

had then its due influence on the early improvers of Science. Geometry originating at first in the art of measuring the fields, was extended to other departments of knowledge, and gave rise to loftier and more difficult problems. Astronomy was enriched by a regular succession of observations, and though the spring of the mighty movements of the celestial bodies lay long concealed from the scrutiny of mortals, the most useful phenomena were obvious to the ordinary observer.

The invention of machines for the abridgment of human labour soon followed, if they were not contemporaneous with the expansion of intellect which such researches originated. The Mechanic Powers must, in some form or other, have been early suggested to mankind. There is no age, indeed, so ignorant and barbarous, in which we can imagine them to have been unacquainted with the use of levers and wheels, so necessary for the transportation of heavy loads and the erection of stupendous structures. The superiority of each successive age consisted only in the skilful combination and application of these simple powers. Science has ever in such cases lent her powerful aid, and enabled the philosopher to wield the ordinary powers of nature with a gigantic force and skill. Such must have been the early history of human knowledge; in all probability its progress would have been more rapid, had not fanaticism and ambition frequently obscured the light of genius for a long series of ages. As a fire, however, concealed beneath the embers, it has been relumed in happier times, at the inspiration of a kindred flame, and has at length burst forth upon the world, with that blaze of intellectual glory which now so brightly irradiates the greater portion of the habitable globe.

The Fine Arts, which have ever possessed charms for mankind, more powerful than those of Science or even the useful arts, owe their origin and commanding influence to an immediate comparison with nature. The expression of the passions in the simplest and most natural language and tones of voice, laid the foundation of the kindred arts of Poetry, Music and Eloquence. The delineation of the objects of those passions on the first smooth surface that presented itself, or the formation of their image in the first soft mould that was subjected to the pressure of the hand, became, in like manner, the basis of the sister arts of Painting, Statuary, and Sculpture. The same causes which gave an early origin to the Fine Arts, produced in them an early degree of excellence. They seem to have shot up at once into perfection, long before the phenomena of nature and her laws had become the subject of philosophical investigation. With the exception of Astronomy, none of the physical sciences seem to have arrived at any thing like system, previous to the composition of the noblest specimens of the fine arts. The supernatural effects ascribed to the Lyre of Orpheus, of Linus, and of Musæus, sufficiently show the splendour of their achievements. The Promethean animation given to the lifeless statue, and the grandeur and simplicity of the epic poem, form an early and a striking contrast to the feeble advances made in the history and economy of the material world. The summit of excellence to which Homer, Thucydides, Demosthenes, Apelles, and Phidias, reached in their respective spheres, while mankind were ignorant of the great laws of the universe and the causes of the most common natural appearances with which they were surrounded, must appear remarkable to us, while contemplating the efforts of the moderns in the very dawn of their Literature and Science. It would seem as if men, satisfied with the first efforts of their ideal powers, or awed by the grandeur of their conceptions when embodied in forms surpassing their expectations, were willing to let fancy gloat on the images before them, and cared not to exert the imagination, much less the reason, on pursuits of a higher and more exalted nature.

Thales and the Ionic Sect. The period, however, approached when a new and more useful impulsion was to be given to the human mind. The glimmering twilight which had so long overspread the nations was about to be dispelled. The lamp of Science which had hung so long concealed in the fanes of eastern idolatry and superstition, bedimmed by the gloomy and debasing artifices of Chaldean magi, and enveloped in the mystery of Egyptian priests, was about to be relumed in more favoured climes. The sages of Greece travelled into foreign countries, visited the seats of ancient learning, and returned fraught with the wisdom of the east. A host of eminent men arose in succession, and shed a glory over their native land. The Ionic sect of philosophers was founded by Thales about six centuries before the Christian era. With him the authentic periods in the history of Science seem to begin. Though, previous to this period, the Chaldeans boasted of celestial observations at Babylon for 1600 years, and the Egyptians for a period nearly as ancient; and though Cadmus had, 850 years before, introduced the Phenician letters into Greece; yet the ascertaining the height of a pyramid by means of its shadow was considered an achievement worthy of this early sage. The geometrical propositions, however, which he is said to have discovered, in addition to his astronomical knowledge,—particularly the foretelling of an eclipse,—entitle him to higher praise. His successors, Anaximander, and Anaximenes, continued the Ionian line, and taught the doctrines of the same school under various modifications. Though the knowledge of nature possessed by those early philosophers was but superficial, it was not the less aspiring. They conceived every substance to be composed of four elements, fire, air, earth and water, but combined in various proportions. Earth and water were considered as naturally ponderous and inert, while air and fire were fancied to be endued with elastic virtue, and possessing lightness and activity. According to this system, the earthy matter settled towards the centre, while the aqueous fluid rolled along the surface of the globe. The air and fire, or æther, soared aloft,—the former filling up the whole of the sublunary region, and the latter streaming through the boundless extent of space. The same pure lambent fluid, collected into globular masses, formed the groups of stars; while portions of its divine essence descended to animate terrestrial beings and communicate the vital spark. These notions, so like the colouring of fantastic dreams, were no doubt firmly believed in former ages, and, by their influence on the vulgar mind, became powerful auxiliaries to the worshippers of the muses.

Seven Sages of Greece. The degree of civilization to which the Greeks had now arrived, tended greatly to foster the spirit of speculation. The legislator Solon, about this period, promulgated his laws at Athens; those of Lycurgus having been established about a century before, at Sparta. The great questions of law and government had thus early attracted the attention of mankind. At the court of Periander, king of Corinth, were the seven sages of Greece assembled, and each of them was asked, "which is the most perfect popular government." Bias replied, "That where the laws have no superior;" Thales said, "That where the people are neither excessively rich nor miserably poor;" Anacharsis answered, "That under which virtue is honoured and vice detested;" Pittacus said, "That where dignities are conferred only on virtue;" Cleobulus said, "That which inspired more fear of blame than of punishment;" and Chilo, "That under which the laws are more regarded than the orators;" Solon's decision, which was esteemed the wisest, was, "That government where an injury done to the meanest citizen is considered as an insult to the whole community." Such were the invaluable maxims which formed the basis of the legislature of Greece, and held up to the admiring world examples truly worthy of imitation, in jurisprudence and civil polity. The Olympic Games, which had been instituted at a very early period, (about thirteen centuries before the Christian era,) had been revived by Iphitus king of Elis, and afforded the philosophers, poets, historians, and orators of Greece, the grandest arena for the display of their talents, that ever graced the annals of any country. Before their assembled countrymen they strove who should excel in all that was worthy of being called great or good among men, and the spirit of emulation thus excited was productive of the happiest effects. Learning and the arts flourished apace, and being freed from the trammels of despotism, under which they had languished in the country of their birth, rose to an eminence far surpassing that of the countries of the east, hitherto the most celebrated in the world.

Pythagoras. Soon after the periods of which we have been speaking, arose one of the most eminent sages of antiquity. Pythagoras, who flourished about five centuries before our era, was the founder of the Italian school, and was the first who assumed the modest, but auspicious, name of *Philosopher.* He was a native of the island of Samos; and on his return from those travels into Egypt, Persia, and India, during which he had acquired that vast fund of knowledge for which he was so renowned, he was viewed with awe and veneration by his countrymen during the celebration of the Olympic games. Aware of the prejudices of mankind, those idols which Lord Bacon long afterwards so fancifully, but justly described, he cautiously introduced those doctrines to public notice, wherein he differed from the mass. A long probation alone rendered his disciples able and willing to receive those truths which constituted the tenets of his philosophical creed. The study of Mathematics appears to have been absolutely necessary for the comprehension of some of his doctrines. Certain it is that these sciences were indebted to him for some fine discoveries, particularly, that respecting the relation between the sides and the hypotenuse of a right angled triangle, which now forms the forty-seventh proposition of the first book of Euclid's Elements,—a theorem more essential to the perfection of Geometry, than any that can be named; and if we may judge by the story of his sacrificing a hecatomb to the Muses on the occasion of its discovery, he seems to have had a foresight of the magnificence of the edifice that was, in after ages, to be built on its foundation. Pythagoras also brought Music to a great degree of perfection, both in theory and practice. Having his imagination, like that of Kepler in modern times, full of the beautiful relations and properties of numbers, which he cultivated with the greatest enthusiasm, he is said to have transferred his musical ideas to the harmony of the celestial motions. Arriving, by the force of his genius, to the sublime conception of the true system of the universe, he is supposed to have veiled the noble discovery under a splendid allegory. Under the symbol of Apollo playing on the lyre, he is said to have taught his chosen disciples, that all the planets, including the earth, are inhabited worlds, revolving round the sun as a common centre; and, to have maintained that those bodies, while they circle round that great luminary, perform a most harmonious concert, though such ravishing and heavenly sounds are lost to our gross ears, and drowned amid the jarring noise which prevails below. This great philosopher is also believed to have been the first who discovered that Lucifer and Hesperus, or the morning and evening star were the same planet, and made that noble conjecture respecting the milky way, so finely alluded to by Milton:

> "Which nightly, as a circling zone, thou seest
> Powdered with stars."

Grecian Poets. The genius of Greece was now rapidly advancing to her zenith. Her tragic and lyric poets had kindled their torch at the lamp of philosophy, which now shone with an uncommon splendour over that favoured country. Though epic poetry had long ago reached its summit of excellence in the immortal poem of Homer, yet the passions and the feelings, and even the understanding, as well as the moral sense, were called into a higher field of contemplation, by the splendid compositions of the three great tragic poets, Æschylus, Sophocles, and Euripides, who flourished between 500 and 460 B. C. Their works abound with the sublimest flights of imagination and eloquence that ever graced mere human writing. What, for instance, can equal the following passage from the "Œdipus Tyrannus" of Sophocles, even though it labours under the disadvantage of translation:—" O for a spotless purity of action and speech, according to those sublime laws of right, which had the ethereal heavens for their birth-place, and God alone for their author—which the decays of mortal nature cannot change, nor time cover with oblivion; for the divinity is mighty within them, and waxes not old!" The sublimity of Pindar, the loftiest of the Grecian lyric poets, who flourished a few years before the tragedians, is perhaps superior to that of the latter; but it is of a kind less calculated to rouse the more amiable feelings and moralities of our nature. This is no doubt owing to the loftiness of his subjects, which were connected with all that was reckoned noble and praiseworthy by his countrymen. He sung those celebrated games of Greece, " quorum pars magna fuit," and was himself rewarded in the very place and manner which he has rendered immortal in his songs. It is a remarkable fact in the history of the world, that a number of eminent men have always appeared at the same time. The immortal Phidias arose at this period, and produced those splendid works of which it is the lament of the moderns that some fragments and descriptions only remain. However much, indeed, they may have excelled the ancients in the ethical and physical sciences, all their progress in the Fine Arts, falls far short of the Parthenon, and the statues of Minerva and Jupiter Olympius. Such achievements as those, require a genius, like Phidias, whose whole soul, filled with the gorgeous visions of the elder time—the dark legends of gigantic strength—and the feelings of a power and a glory departed from men,—shall catch the spirit of ages gone with the years before the flood, and transmit it to after generations in the most durable of earthly memorials.

Grecian Philosophy. Philosophy kept pace with the march of intellect and liberty in Greece. The doctrines of Pythagoras were promulgated by his disciples, of whom the most eminent was Empedocles, the Sicilian, who flourished about this period. He seems to have had some obscure notions of the theory of attraction and repulsion in the corpuscular philosophy. Xenophanes, the founder of the Eleatic sect, drew some accurate geological conclusions from the discovery of marine fossils in the bowels of the earth, and on the tops of the highest mountains, inferring that the exterior crust of our globe had, at some remote period, been submerged under the waters of the ocean. His follower Leucippus, anticipated the idea of a centrifugal force. But it was reserved for Democritus, who flourished during the Peloponnesian war, to extend, correct, and improve these doctrines of his predecessors. He made considerable advances in natural philosophy, and rectified the erroneous notions which prevailed before his time, respecting the existence of a plenum and a vacuum, and levity, as attributed to the elements of air and fire. He discovered the fundamental principles, that the weight of bodies is proportional to their mass, and that they would fall in the same time, in a vacuum. From his acquirements and learning, Lucretius, in his elegant poem on the "Nature of Things," bestows on him the fine appellation of "pater et rerum inventor."

Confucius. While philosophy and the arts were thus rapidly extending in Greece, an eminent philosopher had made his appearance in the East. China, a country which has always made great pretensions to high antiquity, early civilization, and remote astronomical observations, had produced the great Confucius, who flourished about four or five centuries before the Christian era. This philosopher, who has been called the Socrates of the east, is chiefly celebrated for his moral and political maxims, as, like the Grecian philosopher, he turned his attention almost entirely to the moral improvement of his countrymen. Much has been said by modern infidels respecting the excellence of the maxims of Confucius, especially as regards the duty of man to man. It is affirmed that he inculcated our Saviour's golden precept, "Do unto others, as you would that they should do unto you;" but the same sentiment was expressed by several of the Grecian sages, and by Cicero, very nearly in the same words. What, however, do such facts prove, or how do they in any way invalidate the divine mission of Christ? He did not come to abrogate the law originally impressed on man's heart and conscience, but to establish that law by new and more powerful motives. Every good feeling and sentiment that arose in the human mind, was an emanation from the divinity; and it would be wonderful indeed if the author of the sublimest system of morals that was ever promulgated to the world, should not have adopted any maxim that so manifestly bore a divine impress, however well it might have been known, or by whomsoever it might have been at first appropriated. He who, in the beginning of time, made the worlds,

> "Who rounded in his palm those spacious orbs,
> And bowl'd them flaming through the dark profound,"

required not the assistance of heathen philosophers, in laying down rules of conduct for his disciples. As in the regions of external nature, the produce of a thousand hills was his, so in those of philosophy and morality, the gems of truth which sparkled amid the rubbish of many ages, were his unquestionable property, and could only be restored to their pristine purity and situation in the Christian code, by their original author.

Socrates arose at a period when philosophical sects had increased so much throughout Greece, that the true end of knowledge seemed to be abandoned for the love of system. This philosopher, who flourished at Athens about 400 B. C. was eminent for the sublimity of his genius, the simplicity of his manners, and his happy talent for investigating truth and exposing error. Disgusted with the absurd sophisms and vain pretensions of many of his contemporaries, he forsook the study of nature founded on mere speculation, and recommended that philosophy alone which is established on fact and experiment. He justly considered that the first step to real knowledge was to discover our ignorance; hence he took pleasure in exposing every kind of hypocrisy and false learning. The method he adopted, which is denominated the *Socratic Dialogue*, was well calculated to produce the effect he desired; by seeming to be desirous of acquiring a knowledge of the opinions and systems of individuals, he drew from them such concessions in the course of conversation, as showed the absurdity of their tenets; these he afterwards employed to overthrow their imposing and flimsy fabric, by turning their own arguments against themselves. His chief object was to diffuse instruction among the body of the people, rather than to confine it to a few. Hence he is finely said to have been the first sage who brought philosophy down from heaven to earth. We would willingly draw the veil over the close of the life of this illustrious man, when we reflect that truth and virtue have too often been ill rewarded, even though they escaped the glory of martyrdom.

Platonic School. Plato, the most eminent of his disciples, soon rivalled his master in fame. He was distinguished both as a philosopher and a mathematician. He imbibed his taste for the pure sciences while he studied the doctrines of the Pythagoreans. In the grove of Academus, near Athens, under the shade of spreading planes, he taught the youths of Greece those sublime tenets of his mystical philosophy, which laid the foundation of his after renown. He was the inventor of the beautiful method of Geometrical analysis, which became so powerful an instrument in directing the investigations of succeeding geometers, and extending the boundaries of Science. He is said to have been the discoverer of the Conic Sections. Certain it is, however, that before his time comparatively little progress had been made in geometry, as a science, and that he considered this kind of knowledge a necessary qualification in his disciples. The mensuration of rectilinear figures was no doubt long known, its origin being ascribed to the Egyptians; but Hippocrates of Chio appears to have been among the first who attempted to find the area of curvilinear figures. Foiled in his attempts at the quadrature of the circle, he discovered the method of squaring that portion of it called a *lune.* The problem of finding *two mean proportionals* excited much interest at this period. It is said to have arisen from that proposed by the oracle at Delos, *to double the cube,* the solution of which was to allay the plague which then raged in Attica; a fiction probably invented to give an air of importance and mystery to the problem. Though this problem is impracticable by plane geometry, yet it was solved both by mechanical construction and the resources of the higher geometry, which was cultivated in the time of Plato. He himself, his master Archytus, and his scholars Eudoxus and Menechmus gave solutions of it, the latter of whom, especially, deserved praise for his method, as being the first known application of the geometric *loci* and the *conic sections.* The *trisection of an angle,* another problem beyond the limits of plane geometry, gave rise to new discoveries in the Platonic school. The *quadratrix* was invented by Deinostratus. The properties of the five *regular solids* were also investigated by the Platonists; hence they were denominated the *Platonic bodies.* Geometry was applied soon after this period to Astronomy, by Eudoxus and Autolycus.

Aristotle, the most comprehensive genius of antiquity, called the Stagyrite from the place of his birth, flourished about 360 years B. C. He was the illustrious disciple of his illustrious master Plato. As his celebrated pupil Alexander aimed at the universal conquest of the civilized and barbarian world, so he sought to embrace both the natural and moral, within the single grasp of his capacious mind. Though he founded the Peripatetic school at the Lyceum, yet the progress of his opinions in Greece was little, compared with that despotic sway which they for ages maintained in Europe, over the learned. It is said by some historians that he was the author of 4000 volumes, of which scarcely twenty are now extant. No philosopher, either in ancient or modern times, ever took such a vast range of disquisition, and yet he is remarkable for soundness of judgment, precision of thought, and singular acuteness. His great work on Natural History, is a wonderful production, when we consider the period of its appearance. He was the founder of Comparative Anatomy, and the improver of Meteorology, Mechanics, Physics and Astronomy. In his works on these subjects, amid much useless matter, there are to be found many fine remarks and just conclusions, and not a few interesting doctrines worthy of a better day. He wrote treatises also on Mathematics and Music, and the fragments of these which have escaped the ravages of time, prove the great extent of his knowledge in these sciences. His Rhetorics and Poetics are such master-pieces of their kind, that they have never yet been excelled, and the moderns still bow implicitly to their laws, while his authority in Natural Philosophy and Metaphysics has long since been exploded. His *Organon,* now deemed the most useless of all his works, and certainly, as a method of discovering truth or detecting error, perfectly futile, is still valuable for the *synthetic* mode of instruction which it unfolds, and which is still followed in the mathematical sciences.

Alexandrian School. It is a remarkable fact that the exact sciences not only flourished in Greece when literature and the fine arts existed in their greatest splendour, but continued to advance after the latter had become retrograde. Poetry, eloquence, and sculpture, soon began to decline, while all parts of the pure and mixed mathematics were rapidly extending. A short, but brilliant period only has been allowed, in most countries, to original excellence in the literature and arts which depend upon the imagination. The exercise of that power, seems, like the liberty of the turbulent republics, to lead, after a few generations, to its slavery; but the reason, a better governed kingdom, goes on making acquisitions which are imperishable, and perpetually accumulating. The science and literature of Athens, that once mistress of the intellectual world, were transferred to the other countries bounded by the shores of the Mediterranean, and particularly cherished by Ptolemy king of Egypt, one of the sharers of the vast and unwieldy empire of Alexander. The school of Alexandria, founded by this prince, in the magnificent edifice styled the Musæum, and enriched with an immense library and a splendid observatory, produced an extraordinary succession of eminent men. This royal establishment was for nearly 1000 years, the resort of the most illustrious geniuses of ancient times, and conferred incalculable benefits on the human race. A host of the ablest mathematicians shed a lustre on the first three centuries of the Alexandrian school. Euclid, one of its brightest ornaments, digested his immortal *Elements of Geometry,* and raised a monument to his fame,

> "Quod non imber edax, non Aquilo impotens
> Possit diruere, aut innumerabilis
> Annorum series, et fuga temporum."

This lucid genius wrote treatises also *on Conics, plane loci,* and *porisms,* a species of geometrical proposition, which, after being involved in obscurity for ages, from the loss of his work, was elucidated by three eminent mathematicians of modern times, Simson, Playfair, and Brougham. The works on Music, Astronomy, Optics, and Mechanics, ascribed also to Euclid, will at least not lessen his merit, when we consider the early period at which they were written. Accurate Astronomical observations were first made in the Alexandrian Observatory, by Aristillus and Timocharis, about 300 B. C. The astronomical poem of Aratus, entitled "*Phenomena,*" illustrative of the opinions of Eudoxus the Pythagorean, and so popular among the ancients, as to be translated by Cicero and Germanicus, was written shortly after this period. Paul, in his admirable sermon at Athens, makes the following quotation from this poem, when speaking of the *Unknown God* whom they ignorantly worshipped:—"*του γαρ και γενος εσμεν.*"

Archimedes. The most inventive genius which antiquity ever produced, was the much-famed Archimedes, a native of Syracuse, who flourished 250 B. C. The achievements of this philosopher in pure science were only excelled by his real discoveries in Natural Philosophy, which first took its genuine form under his plastic hand. He gave an unlimited extent to the notation of numbers, and founded the method of indivisibles, which led him to the finest discoveries in Geometry. By this means he determined the area of the parabola, the first curve that was exactly quadrated; he made a very near approximation to the quadrature of the circle, and unfolded the beautiful relations that subsist between the cylinder and its inscribed cone and sphere. He was the first who illuminated the sciences of Mechanics and Hydrostatics by the light of Geometry, and his advances were accordingly splendid and triumphant. He appears to have been the first who noticed the centre of gravity in bodies, and he determined it in a number of figures. The properties of spirals and of conoids and spheroids were also among his discoveries. He developed the principles of equilibrium in floating bodies, and thus traced the elements of naval Architecture. He was the first who demonstrated the properties of the lever and some other mechanic powers, and who showed their vast practical application. The story of his boast is well known: "Δος που στω και την γην κινησω." The detection of the fraud in the fabrication of Hiero's golden crown, on the principles of specific gravity, is equally notorious. His success in applying his immense mathematical and mechanical knowledge to practice, in defending his native city from the Romans, have conferred no less renown on his name. The powerful engines which he constructed enabled his countrymen to resist, for three years, the united efforts of the fleet and army of the enemy; and it is to be regretted, for the honour of science, that the relaxation of their ordinary vigilance one fatal night should have laid their city open to stratagem, and involved it in the horrors of an assault, which terminated alike the mortal career of this amazing genius, and their own existence as a wealthy and independent state. The skill of Archimedes appears to have shone equally in Astronomy and Optics as in other branches of Natural Philosophy. Of his discoveries in the former, no accounts remain, except of his determination of the sun's apparent diameter, by a very accurate method, and his deduction from thence of its distance from the earth; he is said also to have constructed a machine for exhibiting the motions of the heavenly bodies, so remarkably ingenious, that Cicero employs the fact as an argument against those who denied the existence of a God. Among his optical inventions, that of burning mirrors, and their wonderful effects, are well known. The fact of the Roman vessels being set on fire by their means, during the siege of Syracuse, was long doubted till its practicability was demonstrated by Buffon.

Aristarchus and Eratosthenes. The broad and ample base of the pyramid of science had been now laid, and the irrefragable and eternal truths of Geometry had for ever rendered it impossible to be shaken. Astronomy began to extend its domains. Aristarchus of Samos had devised an ingenious mode of determining the distances of the sun and moon, made an observation of the solstice, and attempted to revive the Pythagorean system of the universe, which had been rejected by Aristotle. Eratosthenes, a mathematician of the Alexandrian school, determined the obliquity of the ecliptic to be $\frac{11}{83}$ of the circumference, and had the honour of being the first who measured an arc on the surface of the earth. He invented the *Sieve*, a method of finding prime numbers, and several other ingenious mathematical contrivances. His literary and poetical acquirements, in addition to his scientific talents, procured him the esteem of his contemporaries, as a universal genius.

Apollonius of Perga, a genius scarcely less illustrious than Archimedes, was distinguished among the ancients by the name of the *Great Geometer*, and flourished at the Musæum, about 200 B. C. He obtained this noble appellation from his discoveries in the *Conic Sections*, on which he wrote a treatise in four books, the last three being his own invention. In this work so wonderfully did he display his powers in the management of the ancient geometry, that he treads on the threshold of some of the finest modern discoveries. The lost treatises of this great genius, of which the titles were given by Pappus, have exercised the ingenuity of the most skilful of the modern mathematicians, in their attempts to restore them. The problem of *tactions*, was solved by Vieta and Newton. The *sections of ratio and space*, were restored by Halley. The problem of *determinate section* was resolved by Simson. The problems of *inclinations* and *loci plani* were also restored by Simson and others. With Apollonius the progress of the Greek Geometry in the Alexandrian school seems to have terminated, and the labours of his successors were either turned to the improvement of Astronomy, or confined to the writing of commentaries on the works of those gigantic geometers who had spread such a glory around that ancient temple of science.

Hipparchus of Bithynia, who has been styled the father of Astronomy, flourished at Alexandria about 140 B. C. He discovered the precession of the equinoxes, and the inequality of the periods between those points. He approximated very nearly to the exact length of the year, ascertained the distance of the moon, and rectified that of the sun. The motion of the signs of the zodiac *in antecedentia*, suggested to Hipparchus the idea of ascertaining and registering the positions of the principal fixed stars; he also made a catalogue of eclipses for 600 years; thus he laid the basis of the first Astronomical Ephemeris. He was likewise the first who determined the latitudes and longitudes of places on the surface of the globe by celestial observations. The appearance of a new star in the heavens led him to the grand conjecture of the motion of the stars which were considered fixed, a discovery which has so recently been established by Herschell, South, and Struve. Overlooking, however, the true notion of the solar system, he unfortunately introduced the hypothesis of Eccentrics and Epicycles to explain the inequalities of the sun's motion, which, being afterwards adopted by Ptolemy, proved an enormous incumbrance to science.

Ptolemy. The next philosopher of note in the Alexandrian school, was Ptolemy the Astronomer, who flourished at a period about as long after the Christian era, as Hipparchus did before it. He was a most excellent and indefatigable observer, and he not only improved every branch of Astronomy, but he corrected the errors of Hipparchus and others, and digested the multifarious discoveries that had been made before his time, along with his own, into one great system, which he published under the title of the "μεγαλη Συνταξις," or "The great Construction," called by the Arabians, "Almagest." He discovered the evection of the moon, and wrote a treatise on Optics, in which he explained the nature of atmospherical refraction. He was also the author of a work on Geography, in which he applied the theory of projections, which he had invented, to the construction of maps. The study of spherical trigonometry was begun by Hipparchus, extended by Theodosius and Menelaus, but reduced to a practical form by Ptolemy. He adopted and exhibited in his great work, the ancient system of the world, which placed the earth in the centre of the universe, and which has been named after him, the Ptolemaic system. Other philosophers of the Alexandrian school applied themselves to mechanics, but their advances, compared with those of Archimedes, were feeble and insignificant. The genius of Greece, which by this time was fast sinking under oppression, was at length evaporated in unsuccessful struggles for liberty,—and with liberty fled every thing that was valuable in art, science, or philosophy. The Romans had now become masters of the world, and humble imitators of the Greeks, they never produced, during the whole period of their empire, a single genius in those valuable branches of human knowledge, that could equal, much less surpass the achievements of that ingenious people.

After the decline of the Roman empire, and the burning of the Alexandrian library—that storehouse of the collected wisdom of ages—Europe had fallen into such a convulsed state, by the irruption of Northern hordes, that science was totally neglected, and every thing gave way to the ravages of war, and the overwhelming tide of religious superstition. The Arabians actuated by the fierce spirit of a false religion, which had newly sprung up in their quarter of the globe, began to spread the terror of their arms in all directions. Having overrun Egypt, Syria, and Persia, in the East, they turned towards the West, made themselves masters of Spain, and, penetrating into the interior of France, threatened at last to extinguish the very name of Christianity. Checked, however, by the rudeness and poverty of the natives, or by the inhospitality of less favoured climes, and perhaps satiated with the thirst of conquest, they soon abated the fervour of their warlike zeal, and their ambitious enterprizes at last yielded to the arts of peace. Fortunately some remains of Grecian Literature and Science had escaped the general conflagration of the works of the ancients, and the Arabians, under the influence of a spirit that reflects on them the highest honour, carefully collected all that could be found of the philosophical writings of that wonderful people, and caused them to be translated into their own language. Their princes rewarded such undertakings with unbounded liberality; they filled their palaces with those precious relics of science; and, attracted by the beauty of astronomical researches, they adorned their courts by the erection of splendid observatories.

Arabians. The intimate connection of Geometry with Astronomy led the Arabians to cultivate both sciences with ardour; and, destitute of the speculative genius of the Greeks, they turned their efforts chiefly to their practical application. Hence they soon became expert calculators and accurate observers. Almamoun, the son of the celebrated Haroun al Reschid, who reigned at Bagdad in 814, observed the obliquity of the ecliptic and measured the length of a terrestrial degree in the plains of Mesopotamia. Of the astronomers protected by this prince and his successors, Albategni was the most eminent. He ascertained, in 880, the eccentricity of the solar motion, and discovered the change of the place of the sun's apogee. Ibn Junis, at Cairo, in 1000, determined the length of the year, within 2′ of the truth. To the Arabians we owe several improvements in Trigonometry. They first employed the *sines* of angles instead of the *chords*, and introduced the *tangents* into their calculations. Arithmetic took from them that permanent form which it has since preserved by the introduction of the decimal notation—one of the most important steps that was ever made in the progress of Science. This beautiful and simple invention they did not arrogate to themselves, but acknowledged that they borrowed it from the nations of India. The use of these Indian characters was carried by them into Spain, whence it was transferred to the rest of Europe.

Croisades. During these enlightened periods of Arabian history, the fairest portions of Christendom were enveloped in intellectual darkness. The savage arts of war and the intrigues of a cunning priesthood, had conspired to reduce man to a state little better than that of absolute barbarism. His restless and uncontrolable spirit was, in these times, forced to expend its energies in the severest sports, or the most wanton depredations. Science, during these middle ages, was reduced to a very low ebb; it was preserved, however, from becoming totally extinct. The pilgrimages which were undertaken to the shrines of saints, and the visits paid to Rome from every corner of Europe to which her influence extended, served still to keep alive the feeble light of knowledge which had survived the wreck of ages. The Croisades, those expensive armaments which were raised during the period from the twelfth to the fourteenth century,

"when the peers
Of Europe, by the bold Godfredo led,
Against the usurping infidel display'd
The blessed cross, and won the Holy Land,"

are regarded by many as the main cause of the renovation of the human mind in the West. The intercourse produced, during the cessation of hostilities, between the Croisaders and the Saracens who surpassed them in knowledge and refinement, as well as the information obtained by foreign travel, tended greatly to advance the former in the knowledge of the arts and sciences which had been driven from Europe. To this origin is ascribed many of the subsequent improvements which had a polishing and invigorating effect on the progress of society. During these benighted periods, when the streams of ancient philosophy had been almost completely dried up, and no trace left of their source, several useful arts arose, which were destined to lend their valuable aid to the advancement of science. The making of paper was invented about the year 1100, and was the first step to that immense stride afterwards made by the art of printing. Salvino Degli Armati constructed convex lenses for spectacles about the year 1285, thus still farther preparing the way for the use of that grand invention.

Roger Bacon, who flourished in the thirteenth century, was the most eminent natural philosopher of that period, and his name shines like a star amid the general gloom. He appears to have anticipated several chemical and philosophical discoveries of later times. The invention of the magic lantern and telescope has been attributed to Bacon, though, probably, his attempts merely showed others the way; he was acquainted with the construction of certain locomotive carriages, and aeronautic machines; and he gives a description of the diving-bell. It is said that he was familiar with the properties of gunpowder, though the invention has been attributed to Schwartz, a German monk, who lived at a later period. The eastern nations were, however, early acquainted with the deflagrating property of nitre, which was introduced into Europe by the Croisaders, and probably the art of making gunpowder itself. This invention has wonderfully extended the empire of man over Nature, and may indeed vie with the art of printing, in those improvements which they have mutually introduced into society. Wars have been rendered less frequent and sanguinary than in ancient times, by the expense attending the raising of armies, while the arts of peace, have been greatly indebted to its tremendous power in tearing asunder solid rocks of stone. It appears not to have been employed in Europe till about the year 1330; artillery was first used by the Moors at the siege of Algesiras, in 1334; and in 1346, King Edward employed four pieces of cannon, at the memorable battle of Cressy.

Mariner's Compass. The Greeks, though acquainted with the attractive power of the magnet, seem to have been ignorant of its wonderful property of pointing towards the north, the discovery of which is attributed to the Chinese. The Croisaders are alleged to have brought a knowledge of this discovery from the east; but it was first employed in Navigation, by Gioja of Amalphi, near Genoa, about the year 1260. The declination of the magnetic needle seems to have been known very soon after the discovery of its directive property, as it is mentioned by Peter Adsiger in a MS. dated 1269. Aided by this wonderful invention, man soon ventured to explore the utmost limits of the ocean, and wandering, at first, in fear and uncertainty, wasguided by an irresistible power to the discovery of a New World. The thirst for knowledge had begun to rouse the latent energies of human ingenuity, when an invention occurred which may be justly esteemed its noblest achievement, when we reflect on the incalculable benefits it has conferred on our race.

> " 'Tis to the pen and press we mortals owe
> All we believe, and almost all we know."

The art of Printing is said to have been first invented at Haerlem, about 1430, but it is generally attributed to the ingenuity and perseverance of Schoeffer and Guttenberg, assisted by the wealth and the patronage of Faust, a citizen of Mentz. It was introduced into England by William Caxton, and in the short space of thirty years arrived very nearly to that high degree of perfection in which it now exists. The art of painting, which had been revived by Cimabue about the time of Roger Bacon, received at the same period, such a wonderful improvement, by the invention of engraving, that its divine productions were rendered as imperishable as the works of Literature and Science by that of printing. Those who studied the manuscripts of antiquity, which had escaped the ravages of time and the barbarity of nations, now saw a field opened for the exertions of genius which had never been anticipated by the most sanguine expectations of philosophers. Their most ardent hopes for the means of advancing science was infinitely surpassed. Much was to be done, however, before this great invention could be rendered useful to the mass. The repositories of the ancient treasures were to be made accessible; the knowledge of the languages in which they were written was to be acquired; the manuscripts were to be decyphered, and the skill of the grammarian and the critic were to precede that of the mathematician and the philosopher.

Literary Establishments. The monasteries and other religious endowments afforded an asylum to the explorers of ancient lore, and part of the ample revenues of the Romish church were dedicated to the education of youth. Separate academies were established for the purpose of communicating the higher degrees of instruction, and the adoption of the Latin language as the common medium of intercourse over Europe, greatly facilitated the progress of learning. When these seminaries were so much extended as to comprehend all branches of liberal knowledge, they were denominated "General Studies;" and, afterwards, when they were sanctioned by the Bulls of the Roman pontiff, and protected by law, they received the title of "Universities." In these schools, the opinions of Aristotle, which formed the highest object of study, were expounded with incredible diligence, and their authority was held paramount to that of the Holy Scriptures. Thus, the vigour of early genius which, if better directed, might have risen to sublime discovery, was speedily wasted in idle disputations, and, at length, exhausted in empty subtleties. The study of letters, though productive of no immediate advantage to that of nature, still prepared the mind of man for the reception of her great truths. Poetry, as in the infancy of time, began first to attract his attention after the renovation of his powers. Dante and Petrarch resorted to the pure fountains of ancient learning which had been discovered, and the deep enthusiasm and eloquence of the latter poet, produced a great impression on the minds of his contemporaries. The Greek language began to be cultivated, and the princely patronage of the family of Medici, diffused a general taste for literature. The dispersion of the men of letters, occasioned by the taking of Constantinople in 1453 by the Turks, was the cause of the transportation of the remains of Greek Philosophy and Roman Literature to Italy, where they were happily preserved from oblivion.

Arts and Manufactures. The civilization which the Romans introduced into Britain seems to have been either forgotten or very little improved, till the period of Alfred the Great. In his time the English goldsmiths began to excel, and before the conquest, the woollen manufactures had risen to a considerable degree of perfection. About 1250, the linen manufacture seems to have been considerably advanced in England, though embroidery was then much practised. In the twelfth century, silks were principally worn in Sicily. The manufacture of cloth was greatly improved, by the establishment of Kempe and other Flemish weavers in England, in the fourteenth century; and numerous mechanical arts were advanced, about the same period, by the invention of wire-drawing, which was first introduced at Nuremberg. The great increase in the arts of civilization and refinement in the succeeding centuries, produced a greater demand for superior manufactures. This required more labour and skill, and suggested to some happy genius of superior penetration, the great principle of the *division of labour*, by which each individual is enabled to acquire so high a degree of perfection in a single branch of the arts or manufactures, that the whole is much more perfectly and expeditiously performed, than if it had been the entire workmanship of any one artist, though possessed of far greater abilities and experience. The invention of the modern spinning wheel is attributed to Jurgen of Brunswick, in 1530, and England soon afterwards profited by the improvement. Before the end of the century, Lee of Cambridge invented the stocking loom, which imitated the texture of the knit stockings manufactured in Spain about 1550. Mills for drawing wire and slitting iron were first erected about the same period, and Birmingham and Sheffield were, even then, celebrated for their manufactures, and for the germ of that powerful machinery which has since astonished the world by its wonderful productions, as well as by the facility and expedition with which they are fabricated.

Mathematics. With the revival of Literature a new science was introduced into Europe from Arabia, of a name and character unknown to the Geometers of antiquity. The feeble attempts of the early improvers of *Algebra*, gave no indications, however, of that splendid career which it was destined to run in the hands of the modern mathematicians. Even the towering genius of the Greeks, during the most flourishing periods of their philosophy and science, was unable to rise to the invention of the Analytic Art. Diophantus of Alexandria, who is believed to have flourished a few years before Hipparchus, had, no doubt, composed a curious treatise consisting of thirteen books of Arithmetical questions, many of which are of considerable difficulty; but the instrument which he employs, being chiefly an abridgement of ordinary language, is comparatively weak and imperfect, though he manages it with great address and skill. Leonardo, a wealthy merchant of Pisa, who made frequent commercial adventures to the East, was the first who made the science of Algebra known in Europe, about the commencement of the thirteenth century. This science is supposed to have been originally carried from India into Arabia, by Mahomet Ben Musa of Chorasan, about the same time that Gerbert the Monk, otherwise called Sylvester II. first introduced the Arabic system of notation among his countrymen in the Low Countries. The first printed treatise on Algebra, was that of Lucas Pacioli, or de Burgo, published in 1494. The characters employed in this work, as well as in that of Leonardo, which existed only in manuscript, consist of mere verbal abbreviations; thus, showing that this science was in its early state, merely a system of short-hand applied to the solution of arithmetical problems; yet to this simple invention are we indebted for one of the most powerful weapons of modern discovery. The work of Diophantus was given to the world by Xylander in 1575. The utmost extent to which these early writers on Algebra had arrived, was the solution of Quadratic Equations; and even in India, the father-land of the science, their knowledge seems still to be circumscribed within such narrow limits.

Cardan and Tartalea. Italy, which had been the scene of so many revolutions for ages, was now destined to behold the peaceful warfare of Science. The discovery of the method of solving Cubic Equations, the joint result of the labours and skill of Scipio Ferreo, Tartalea and Cardan, forms a remarkable era in the history of the Analytic Art. Ferreo, who was Professor of Mathematics at Bologna, had, in 1508, found out a rule for the resolution of one of the cases of these Equations, which, after the manner of mathematicians in those days, one of his scholars obscurely communicated in a challenge to Tartalea of Brescia, to try their strength in the new art. The genius of Tartalea, being thus called into action, soon enabled him to discover the method of solution and to extend it to more intricate cases. The report of this discovery excited in Cardan of Milan, who was well skilled in the knowledge of Algebra as it was then practised, the most ardent and lively curiosity, and he ceased not to importune Tartalea with the most earnest solicitations, till he had extorted the rules from the latter, under the most solemn promises and oaths of secrecy. Cardan soon discovered their demonstrations, and having extended this important discovery to all kinds of cubic equations, he published the method to the world in 1545, as his own, without any regard to his oaths, or acknowledgment of the man to whom he was so much indebted. However unfair such conduct might be to his contemporaries, he conferred a permanent benefit on Science, and marked a point in the progress of Algebraic investigation, with respect to the solution of equations, beyond which all the efforts of succeeding Analysts have scarcely been able to reach. The irreducible case which falls under Cardan's rule, has baffled all the mathematicians of Europe since that period, and may safely be ranked, along with the quadrature of the circle and the trisection of an angle, among the problems which are doomed to exercise human skill and ingenuity in vain.

Astronomy was the first of the sciences that was regenerated on the revival of learning. It had always been cultivated, even during the middle ages, from its supposed connection with the absurd and illusive science of Astrology, which, as well as alchemy and magic, was prosecuted with great assiduity in those periods of ignorance. Even in the thirteenth and fourteenth centuries, professors of Astrology were appointed in the Universities of Italy, to instruct their pupils in the nature of the influence of the stars. Previous to this period, astronomical observations of an authentic date, about 1278, had been made in China by Cocheouking, whereby the obliquity of the ecliptic was very accurately made known. The Persians had likewise made great progress in astronomy, and Ulugh Beigh, in his capital of Samarcand, in 1437, employed very elaborate instruments in the investigations of this sublime science. *Alphonso*, King of Castile, who flourished about the middle of the thirteenth century, was the first who dared to question the system of the world, which had descended from antiquity, hallowed by the venerable names of Aristotle and Ptolemy. The bold saying of this prince has been justly taxed with impiety, and though on that account deeply liable to censure, it exhibits, in a strong point of view, the difficulty which an accurate investigation of nature always presents to the reconciliation of facts with preconceived theories. Milton, whose learning and genius drew illustrations from every branch of human knowledge, has alluded to this ancient and complicated system in his divine poem;

> " Hereafter, when they come to model Heaven
> And calculate the stars; how they will wield
> The mighty frame; how build, unbuild, contrive
> To *save appearances*; how gird the sphere
> With centrick and eccentrick scribbled o'er
> Cycle and epicycle, orb in orb."

Copernicus. Several valuable improvements had been introduced into astronomical calculations by Purbach and Regiomontanus, two eminent mathematicians of the fifteenth century, when Copernicus arose like a meteor in the midnight sky, and unfolded to the gaze of man the true system of the world. This illustrious astronomer, who was born at Thorn, in Prussia, in 1473, stands at the head of that able phalanx of discoverers, in modern times, who, bursting the fetters of prejudice and authority, discarded every opinion in philosophy not founded on experience and observation. Dissatisfied with the complicated hypotheses of the Ptolemaic system, he examined the works of the ancients now laid open to Europe, in quest of more satisfactory opinions. It is supposed that he borrowed his ideas of the true system from the allegorical notions of the Pythagoreans, and that he applied them to the numerous observations which had been accumulated by the diligence of astronomers. Finding them all in perfect conformity with his theory, he quickly threw aside the Ptolemean epicycles, and in those remarkable phenomena, beheld nothing but the necessary consequences of the combination of the motions of the earth and planets round the sun; thus, he was enabled to calculate the relative distances of the planets from the sun, which, till then, had remained unknown. The marks of that beautiful simplicity which pervades all the works of nature, being impressed on this system, carried with it the most convincing evidence of its truth. The publication of the work which contained the explanation of the doctrines of Copernicus, took place in 1543, only a few days before his death; and, what is remarkable, was earnestly solicited by a Cardinal; while the book itself was dedicated to the Pope. In this work, he promulgated the opinion of the earth's motion with great caution, as if he had been gifted with a presentiment of the opposition it should one day experience. This system, at first, attracted so little attention, that it was rejected by most of the learned, and it lay, as it were, smouldering in secret for half a century, till, by the exertions and the fame of Galileo, it was kindled into so bright a flame, as to consume the philosophy of Aristotle, alarm the hierarchy of Rome, and threaten the destruction of every opinion that had descended from antiquity.

Tycho Brahé. Another eminent astronomer flourished towards the end of the sixteenth century, in the small isle of Huen, at the entrance of the Baltic Sea. There the noble Dane Tycho Brahé erected his famous observatory of Uraniburg, and enriched Astronomy by observations equally celebrated for their number and their accuracy. He employed instruments which were not only the most perfect hitherto constructed, but introduced the valuable improvement of detecting and rectifying their errors by actual observation. He formed a new catalogue of the stars amounting to 777, and discovered almost all the irregularities of the moon's motion, that were known previous to the theory of universal gravitation. He clearly pointed out the nature of atmospherical refraction, and even contrived an instrument for rendering it visible. His theory of comets which was just, and his observations on the appearance of the new star in 1572, gave a severe blow to the physics of Aristotle which were now beginning to fade before the splendour of modern discovery. Unfortunately, he was deterred, by religious scruples, from adopting the true system of the world unfolded by Copernicus, and thus, by one retrograde step, lost the glory of giving the finishing touch to that noble column in the temple of science, which his own invaluable labours had reared.

Kepler. Modern times can scarcely present a name more illustrious than that of Kepler. Born in 1571, at Wiel in Germany, and living at a period when the scholastic philosophy was yet in vogue, and the authority of Aristotle still maintained its ascendancy, he soon rose above the errors of his day by the force of his superior genius. He commenced his splendid career by adopting the planetary system of Copernicus, which was then becoming popular. He corrected the law of refraction, and applied the principles of Optics to Astronomy. In his works he tells us there were three things of which he anxiously sought to discover the reason, from his early youth; namely, why the planets were six in number; why they performed their revolutions in orbits of the dimensions ascribed to them by Copernicus; and what were the laws of these revolutions. In the true spirit of the ancient Pythagoreans, he endeavoured, at first, to account for these phenomena by the properties of number and figure, and by the analogy and harmony of nature. The candour with which he acknowledges his obligations to Tycho Brahé, whose pupil and assistant he afterwards became, for properly directing him in his investigations, cannot be too much admired. Succeeding to his illustrious master in his appointments at Prague, under the emperor Rudolph, he enjoyed the enviable title of "Imperial Mathematician;" there his bold and exuberant imagination, working on the register of the accurate observations of the Danish astronomer, and aided by the most persevering industry and intense labour in calculating and combining them for the space of 17 years, at last drew aside the hitherto impenetrable veil, and disclosed to view those eternal laws which govern the revolutions of the heavenly bodies. Kepler, besides those three remarkable laws which are generally distinguished by his name, made several other important additions to Astronomy. He corrected the errors of Copernicus respecting the parallelism of the earth's axis, and before his death, which happened in 1630, had the satisfaction of applying his immortal theory of the planetary motions to the satellites of the planet Jupiter. When we consider the nature of the discoveries of Kepler, as being elevated far above the observation of ordinary men,—when we reflect on the deep enthusiasm that dwelt in his bosom even from his youth, on subjects of such a profound and exalted nature, and so far removed from what usually interests the human race,—and, above all, when we contemplate that patient, unwearied, and unremitting spirit of perseverance which bore him through the most lengthened and perplexing calculations and hypotheses, at a period when the use of logarithms was yet unknown, and the rules of philosophizing were still in an embryo state,—we must award the homage of our greatest respect and profoundest admiration, to his brilliant and indefatigable genius.

Galileo. The noble army of scientific men was now rapidly increasing. Galileo, the illustrious cotemporary and rival of Kepler, was born at Pisa, in 1564. The news of the happy discovery of the telescope in Holland, having reached Galileo in 1609, he soon re-invented that instrument for himself, and had the singular felicity of being the first to point the wondrous tube to heaven, to observe the varying phases of the planets, and to discover the immutable order and harmony of new worlds. The sensations which must have been communicated, may be more easily conceived than expressed, when first

> "the moon, whose orb
> Through optick glass, the Tuscan artist views
> At evening from the top of Fesolé,
> Or in Valdarno, to descry new lands,
> Rivers, or mountains in her spotty globe."

The earth and the planets were now proved to be similar bodies, and the ancient systems of the universe annihilated by this single instrument, were replaced by a system more suitable to the simplicity and magnificence of nature. When the same illustrious philosopher turned his telescope to the fixed stars, his surprise at finding their magnitude diminished was only surpassed by the splendour of the glorious spectacle laid open to his admiring view; he then discovered that the Almighty had filled infinite space with innumerable instances of his creative power invisible to the naked eye,

> "And sow'd with stars the heavens, thick as a field."

Such extended conceptions of the mechanism of the universe, could not fail to delight and astonish mankind, and to raise their minds far above the grovelling and limited ideas formerly entertained of the power, the wisdom, and the goodness of the Great Author of Nature. The next discovery of the Italian Philosopher was that of the satellites of Jupiter, which he announced in his "Nuncius Sidereus," or "Starry Messenger," under the title of the Medicean stars. His telescope was not sufficiently powerful to detect the remarkable phenomena of the ring of Saturn, though he pointed out those uncommon appearances which led to its discovery. The beautiful crescent of Venus, and the gibbous figure of Mars, enabled him to give the most convincing demonstration that had yet been adduced of the Copernican system, and to verify the sagacious conjecture of its author, that, if the sense of sight were sufficiently powerful, we should see Mercury and Venus exhibiting phases like those of the moon. The singular and still unexplained phenomenon of the dark spots on the surface of the sun, next attracted the attention of Galileo, and enabled him to ascertain the curious fact of the rotation of that luminary on its own axis. So many shining discoveries threw a halo of renown around the name of the Italian philosopher, and produced a host of enemies to whose machinations, and interest with a corrupt and debased church, he very nigh fell a martyr. Instead of meeting with the admiration and gratitude of the learned, as in our days, he was viewed with jealousy and alarm as an obstinate heretic, and innovator. In proportion to the ability which he displayed, and the success with which the promulgation of his doctrines was crowned, so did the unrelenting rancour of superstitious bigotry pursue the venerable genius who had overthrown the idols of antiquity, opened up a new path to knowledge, and almost doubled the faculties of the race. Arraigned before the tribunal of the Inquisition—the most infamous engine of power ever suggested by infernal agents—a council of seven Cardinals pronounced a sentence which, for the sake of those who imagine that wisdom and power are synonymous terms, ought never to be forgotten: " That to maintain the sun to be immoveable and without local motion, in the centre of the world, is an absurd proposition, false in philosophy, heretical in religion, and contrary to the testimony of scripture. That it is equally absurd and false in philosophy to assert that the earth is not immoveable in the centre of the world, and considered theologically, equally erroneous and heretical." In 1663, Galileo, at the age of 70 years, was again brought before the Inquisition, forced solemnly to disavow his belief in the motion of the earth, and condemned to perpetual imprisonment. The very means, however, which the church of Rome took to suppress this heresy, tended only to fan the flame which science had kindled; and, while we look back with regret on the persecution of that venerable sage, we ought to glory in the emancipation of the human mind from that spiritual thraldom which was alike the bane of true religion and sound philosophy.

Fine Arts. The day-spring of knowledge which had thus risen on the human race, had also a regenerating and enlivening influence on the progress of the Fine Arts. Italy, during the fourteenth and fifteenth centuries, produced those inimitable masters of Painting, whose fame rivals that of the ancient Grecian artists, even when in the full tide of their glory. *Leonardo da Vinci,* who was born at Florence in 1452, was the first who gave a prelude of that degree of excellence which was afterwards to be attained in this divine art, and which brought the achievements of the moderns in comparison with those of the age of Pericles. He was the most accomplished man of his age, and merits the esteem of posterity for the universality of his talents, which were successfully applied, not only to poetry and painting, but also to architecture, mathematics, and mechanics. The transcendent genius of *Michael Angelo,* his contemporary and illustrious rival, stamped the character of the Florentine school with grandeur and sublimity. The fame of Leonardo excited in his breast that flame of emulation, which set fire to a train of achievements in the arts more brilliant than had ever before illuminated Italy. The appearance of a new competitor in the field, the immortal *Raphael,* who was born at Urbino in 1483, gave an impulse to mind and a glory to art, which succeeding ages are content to admire without the hope of ever reaching, much less surpassing, by any after effort of creative skill. Angelo, who had striven for the palm of superiority with Da Vinci, was doomed, in his turn, to be outshone by the more splendid genius of Raphael. Yet the history of human ingenuity does not furnish a more miraculous example of undaunted perseverance than that of Angelo in the fresco painting of the Deluge, the very first trial of his skill with that great master of the Roman school. The most stupendous production of his genius was the Last Judgment, which occupied eight years, and contained three hundred figures, executed with such ease, majesty, and grandeur, as not only to strike despair into the minds of his contemporaries, but into those of almost every succeeding generation of artists. The rising renown of Raphael threw the lustre of Angelo's fame partially into the shade. Such was the peculiar modesty and candour of this young artist, however, that he expressed his gratitude to Providence, for having been destined to live at the same period with that eminent man.

The works of Angelo proved a rich mine to the aspiring Roman, and were to him what the immortal poem of Homer had been to the Mantuan bard. The muscular forms, the bold outline, and the energetic attitudes of the Florentine artist, were softened and harmonized in the elegant and graceful productions of the pencil of Raphael. Though the career of this illustrious genius was short, it was splendid; and the fertile age of Leo X. beheld none whose works could equal his in touching simplicity and grace. His celebrated " Cartoons," are well known, and have been often described. The " Transfiguration," a picture of immortal Touch, terminated the labours of this divine artist. None of the immediate followers of these great masters in Italy could equal their productions; and, indeed, a manifest declension in the Fine Arts speedily succeeded. Other masters arose in various places on the continent, and produced works of considerable merit, but the grandeur and natural simplicity of the Italian artists were gone. The Venetian school could boast of their Giorgione and Titian; and the Lombard school, of Corregio and the Caraccis, the former of whom is deemed worthy of being classed in the same rank with Angelo and Raphael. The French school had their Poussin and Lorraine; and the Flemish their Rubens, Vandyke, and Rembrandt,—the latter a genius of extraordinary skill and romantic originality. Such a brilliant galaxy of talent, which had thus succeeded the age of erudition, showed that man possessed powers capable of the most astonishing exertions if properly directed, and that the principle of emulation is the fruitful parent of all that is great and ennobling in Science, as well as all that is elegant and beautiful in

Art. The human mind, has, however, in all ages, required the gigantic efforts of some master spirit to set it free from the trammels of authority, to overthrow the inveteracy of antiquated opinion, and to enable the race to explore with a fearless eye the wide fields of knowledge and of nature.

Mechanics. From the time of Archimedes till the era of Galileo's discoveries, comparatively little progress had been made in Mechanical science. *Guido Ubaldi*, an Italian, in his treatise published in 1577, was the first who attempted to extend the theory beyond the investigations of the ancients. He simplified several of the mechanical powers, and wrote a valuable commentary on the works of Archimedes. *Stevinus*, a Dutch engineer, was the first, however, who passed the limits of mechanical knowledge possessed by the philosophers of the Alexandrian school, and their commentators. He accurately ascertained the force necessary to sustain a body on an inclined plane, and thus discovered the solution of that particular case of the composition of forces, by which the equilibrium of any three forces is determined. His demonstration is extremely ingenious, and remarkable, as being the first solution of a problem which had stood as a barrier in the way of mechanical discovery for ages. He detected the important law in Hydrostatics, that the pressure of fluids is simply in proportion to their depth. As Kepler has been elegantly styled the forerunner of Newton in his Astronomical discoveries, so may this appellation be awarded to Galileo with regard to those in Physical Science. In his treatise *della Scienza Mecanica*, published in 1592, he unfolded the theory of the Mechanical Powers, and developed that important mechanical principle afterwards denominated the principle of *Virtual Velocities.* He extended his investigations both to statical and dynamical questions relative to the doctrine forces, and showed that if the effect of a force be estimated by the weight which it can raise in a given time, no mechanical contrivance can ever increase that effect. Important as these discoveries were, they were eclipsed by others of a more remarkable nature. The theory of variable motion, wholly unknown to the ancients, is due to his penetrating genius. He discovered the law of the acceleration of falling bodies by the action of gravity, both vertically and along inclined planes, and established it both by experiment and mathematical demonstration. It was during his professorship in the university of Pisa, that he made those experiments which laid the foundation of his fame. Having attacked the fundamental axiom of the Aristotelian philosophy, that the velocities of falling bodies were proportional to their weights, he publicly demonstrated its fallacy by letting fall heavy bodies from the top of the church in that city. The experiment attracted crowds of spectators, and the popularity which he thus acquired, drew upon him those persecutions with which the prejudice and jealousy of his enemies continued to harass and afflict this great philosopher through life, and which may be justly esteemed as the only equivalent for the praise of the liberal and enlightened, that an ignorant and bigotted age can bestow. The vibrations of the lamps in the cathedral having attracted the attention of Galileo, he was led, by the train of reasoning which they suggested, to the discovery of the *isochronism* of pendulums, and other properties of pendulous bodies, which have proved so important in Mechanics.

To ordinary observers, indeed, the swinging of a lamp or the falling of an apple, would seem a matter of the most common and trivial occurrence; but to those who are gifted with the "afflatus divinus" of science, such a simple phenomenon often appears pregnant with those sublime principles that are concealed in the womb of nature, and are only considered as simple and obvious after they have been discovered. Hence the truth of the remark, that it is one of the prerogatives of genius to find the highest value in things which ordinary men are trampling under their feet. The true path of a body when thrown obliquely through the air was first demonstrated by Galileo to be a *parabola*, and on this principle he founded his beautiful "Theory of Projectiles," a step of the highest importance to physical science, as it included, in its full extent, the doctrine of the composition of motion. The vibrations of the pendulum suggested to him the means of accurately measuring time by its application to the clock, which he concluded might be employed to find the longitude by means of observations on the satellites of Jupiter. The discoveries of the Florentine philosopher were wonderful indeed for the age in which he lived. Considering the state of knowledge at that period, they required and found in him a depth of philosophical skill, an acuteness of mathematical research, and a comprehensive grasp of mind, of which we shall vainly attempt to form any conception, without retracing the march of genius in his own luminous and elegant exposition of the steps by which he was conducted to those simple but sublime truths, which formed such a noble acquisition to the territories of the kingdom of Science.

Logarithms. The beginning of the seventeenth century was distinguished by one of the most valuable improvements in Mathematical science that ever shone in the history of human invention. An important step had been made in Arithmetic by Stevinus, who introduced the use of decimal fractions in 1590, the notation of which was soon afterwards so much improved by *Napier* as to retain its form to the present day. This highly favoured genius, who was born in 1550, at Merchistoun in Scotland, had early turned his attention to the discovery of a method of shortening those laborious calculations, which the accuracy of astronomical observation and the improvements in trigonometry required. The rapidity with which the progress of discovery was extending the boundaries of Science had rendered such calculations extremely irksome to the ardent minds of the mathematicians and astronomers of Europe. The freshness of Napier's invention, therefore, burst upon them at once, like the relief which the sudden appearance of the sun through the clouds, brings to mariners in the midst of a storm. In 1614, he published his "Canon Mirificus Logarithmorum," at Edinburgh; and philosophers seeing their difficulties vanish before this wonderful invention, received it with universal applause. The idea of employing the terms of an arithmetical series to discover those of a geometrical series, which formed the basis of this immortal work, had once occurred to Archimedes, but for want of a simpler system of notation, it had never been farther pursued; the tide of his ideas had, in fact, soon after flowed beyond it, and in the long series of ages that succeeded, no genius, less lofty than his, arose to complete the discovery, till the torch of Science again illumed the world. The great merit which the immortal Napier had in this achievement, is owing to the state of Science at the period in which he lived. Algebra had still to receive many of its finest improvements, and though Geometry was advancing with rapid strides, the doctrine of Fluxions was yet unknown. The genius of this great inventor appears to have leaped over many intervening barriers which, to less powerful minds, would have presented insuperable difficulties, and, seizing upon the discoveries of a future age, to have compressed them into the single principle from whence his invention emanated. The idea of considering all numbers as powers of a given number assumed as a base, was an expansion of thought which carried him over a century of discovery, and placed him by the side of the inventor of the new Calculus. Logarithms, indeed, contributed in a very high degree to the subsequent progress of science; and, in the hands of modern mathematicians, proved an engine of no ordinary power. In conjunction with the various branches of Analytical science, it has become a gigantic instrument of investigation and discovery; and, like the fabled wand of the magician, has enabled the philosopher to penetrate into the mysteries of nature.

Baconian Philosophy. The march of the human understanding had now surpassed its progress in every former age. Even the brightest periods of antiquity were thrown into the shade by the splendour of modern discovery. The mind of man was on the eve of some mighty achievement, when Bacon arose and bore away the palm of triumph. To secure to the human race, the acquisitions it had won, and to prevent it for ever from returning to that state of intellectual darkness and degradation from which it had so gloriously emerged, it was necessary to ascertain and to fix the laws of philosophical investigation, and to compress them into one grand and ruling principle,

> " that might direct
> Our knowledge, and the scale of nature set
> From centre to circumference."

Such a gigantic effort required the hand of some master genius; and philosophy, at last, taking her flight to our favoured isle, delegated her power to Lord Bacon. Born at London, in 1560, he had been early dissatisfied with the Aristotelian philosophy, still taught in the schools, and soon turned his powerful mind to the contemplation of the state of human knowledge, to the investigation of the causes of its imperfections, and to the formation of plans for its improvement. He clearly saw the vagueness and uncertainty of the physical speculations which at that period still prevailed among philosophers, and he beheld, with the penetrating eye of genius, the want of a connecting link between the sciences and the arts. He perceived the necessity of investigating nature not only by careful observation but by accurate experiment, before man could venture to generalize facts, and found a solid body of knowledge on such an inductive process. He saw, that to discover the Protean forms of material objects, required both the caution and the intrepidity of the experimental philosopher; and that, if he would seize the predominant agent, and unfold the different principles of action, he must press Nature into a corner, and compel the unwilling captive to reveal her secrets. Examples of the true method of investigating nature had been afforded by the discoveries of his contemporaries. Dr. Gilbert of Colchester, particularly, in his treatise, " De Magnete," in which he established terrestrial Magnetism, and laid the foundation of electricity, had furnished an admirable model of philosophical analysis; the various facts were there reduced to a few leading principles, and occasional gleams were thrown on other branches of science. The early germ of the Inductive philosophy, however, is contained in the remarkable advice given by Tycho Brahé to Kepler, on receiving a copy of his " Mysterium Cosmographicum ":—" Argumentum literarum Brachei," says Kepler, " hoc erat, *uti suspensis speculationibus a priori descendentibus, animum potius ad observationes, quas simul offerebat, considerandas adjicerem. Inque iis primo gradu facto, postea demum ad causas ascenderem.*" This valuable advice, which is not surpassed by any of the Aphorisms of Lord Bacon, may be said to comprehend the sum and substance of the *Novum Organum.* From this luminous view of the true spirit of philosophy, so admirably illustrated by the after discoveries of Kepler, Galileo, and others, how easy was the transition to the first sentence of that immortal work! " *Homo naturæ minister et interpres tantum facit et intelligit quantum de naturæ ordine re vel mente observaverit, nec amplius scit aut potest.*" The reformation of religion, in addition to the general progress of the arts and sciences, contributed in no small degree to emancipate the mind of man from the errors of ancient system, and to pave the way for the labours of Bacon. In the " Novum Organum," published in 1620, he divided the causes of error into four heads, which he figuratively denominated the Idols of the Tribe, the Den, the Forum, and the Theatre. The first, are those which are founded in human nature; the second, in the character of the individual; the third, in the intercourse of society; and the fourth, in the systems of the different schools of philosophy. He next arranged the different modes of investigation founded on an induction from facts, under twenty-seven different species; fifteen of which are addressed to the understanding; five serve to correct or inform the senses; and seven to direct the hand in raising the superstructure of art on the foundation of science. The ingenuity and ability displayed by Lord Bacon in thus directing the human intellect in its researches after truth, surpass all praise. The compass of that mind which formed the plan, traced the outline and ramifications of experimental inquiry in branches of science yet to be discovered, must be an object of admiration to all future ages; and before another genius comparable to his can be found, the human race must return to that state of ignorance from which they were so happily emancipated.

Cartesian Philosophy. Various important discoveries succeeded the era of the Inductive philosophy. *Torricelli,* the friend and pupil of Galileo, laid the foundation of Hydraulics by proving that water issues from a hole in the side or bottom of a vessel, with the velocity which a body would acquire by falling from the level of its surface to the level of the orifice. He discovered the reason why water cannot be raised, in pumps, higher than 33 feet—which had been left unexplained by his master—and demonstrated the existence of Atmospheric pressure, by his celebrated experiment of the suspension of mercury in the barometer. *Pascal* suggested, in farther confirmation of this doctrine, the experiment whereby the diminution of that pressure was made known, by carrying the barometer to the top of the Puy de Dome, and thus affording an accurate method of determining the altitudes of mountains. *Otto Guericke,* in Germany, about 1654, completely overthrew all the objections of the Aristotelian philosophers to the pressure of the atmosphere, by the invention of the air-pump, which was afterwards improved by Mr. Boyle. The doctrines of Aristotle, which had been frequently attacked in detail, were now destined to be completely demolished by the penetrating genius of Descartes. This original and inventive philosopher, who flourished about forty years later than Bacon, appears to have been unacquainted with his works. He was equally dissatisfied with the ancient philosophy, and soaring above the influence of prejudice, was hurried away by the ambition of erecting a system of his own. Assuming no other data than matter and motion, he proposed to explain *a priori* the structure and constitution of the universe. Instead of proceeding from the effect to the cause, he reversed the order of the Inductive philosophy, and attempted to proceed from the cause to the effect. The ancients had imagined a *primum mobile,* or kind of homocentric orbs, to account for the celestial motions; Kepler, in the liveliness of his fancy, had conjectured a kind of *animation* and *organic structure;* and Descartes introduced a *plenum,* and *endless vortices,* limiting and circumscribing one another. Absurd as his system of philosophy was, and as ill-calculated to explain the phenomena of nature as any of the former, it maintained its ascendancy over the continent, under various modifications, for the space of nearly a century. In as far as the Cartesian system served to explode the wrangling of the schools, it may be said to have aided the progress of science; but containing in itself the seeds of its own destruction, it was destined at last to be obliterated by the Newtonian philosophy. The other labours of Descartes form a more permanent monument to his fame.

Algebra and Geometry had been making considerable advances since the period of Cardan and Tartalea. Stiphelius, Recorde, Pelitarius and Bombelli, had made improvements in the notation and rules of Algebra. *Vieta,* in his work published in 1600, first employed the letters of the alphabet to denote the known as well as the unknown quantities, by which important step, the symbolical language of this science first became capable of expressing general truths, and, subsequently, such a powerful instrument of investigation. His treatise on "Angular sections" appears to have been the first application of Algebra to Geometry. The discovery of the genesis of Equations, to which *Girard* had made a near approximation, was completed by *Harriot* in 1631, who brought Algebra almost to the perfect form in which it exists at the present day. It was thus prepared for the important step made by *Descartes,* which constitutes a remarkable era in the history of the Mathematical sciences. This philosopher, in his Geometry, published in 1637, showed the application of the Algebraical Analysis to the investigation of the nature and properties of Curves, and first introduced the notion of variable quantity. He solved the curious and difficult problem of the *locus ad quatuor rectas,* in a variety of cases, and invented a method of drawing tangents to curves, in which he was rivalled by *Fermat.* This important branch of analysis was afterwards improved by Roberval, Barrow, and Newton, who was finally led, by his investigations on this subject, to the invention of the method of Fluxions.

The New Calculus. The Mathematical sciences began now to share in the general progress of improvement, which the ferment of discovery had awakened in the mind of man. The ancient method of "Exhaustions," which had been brought to such a degree of perfection by Archimedes, was found to be too cumbrous an instrument for modern investigations. Accordingly, *Cavalieri,* who was born at Milan in 1598, had the good fortune to make the first step in the direct line to the new Calculus. Both Kepler and Galileo had introduced the idea of infinitely great and infinitely small quantities into their geometrical discussions, but Cavalieri, who was a more profound mathematician than either, took up the subject in a regular and systematic form, in his work on "Indivisibles," published in 1635. By this method he arrived at the quadrature of numerous areas, and the cubature of many solids, which surpassed the power of the ancient Geometry, and discovered several new and beautiful theorems. The properties of the Cycloid were unfolded by the same means, and particularly attracted the attention of Torricelli, Roberval, Wren, Wallis, and Huygens. The next important step was made by *Wallis* in his "Arithmetic of Infinites," published in 1600. He effected the quadrature of all curves, where the value of one of the coordinates could be expressed in terms of the other by means of integral and positive indices; but he partially failed, in attempting to obtain the quadrature of the circle, from inability to express the values of those co-ordinates which involved fractional or negative exponents. The remarkable results which such speculations produced, had excited the curiosity of mathematicians both in England and on the Continent. The idea of infinite quantity, after being made the subject of reasoning and calculation, led to conclusions from which, as if by magic, that idea had wholly disappeared, and left the calculator in possession of valuable propositions involving no magnitudes but such as could be readily exhibited.

Newton. The star of genius which had been rising with majestic splendour in the hemisphere of science, at last reached its zenith above our favoured country. Over the birth-place of Newton it shone forth with unclouded lustre, and the beams of its meridian glory were destined to illuminate his path. The invention of the New Calculus, the discovery of the Composition of Light, and of the Principle of Universal Gravitation, all within a period of about twenty years, were a series of more remarkable discoveries than ever fell to the lot of a single individual; and they have encircled the name of the British philosopher with a never-ending fame. Taking up the consideration of the doctrine of "Infinites" at the point where Wallis had failed, he extended it to the case of fractional indices, and thus found the quadrature of the circle and innumerable other curves by the method of infinite series. These investigations first led to the discovery of the Binomial Theorem, and afterwards to the invention of Fluxions in 1666. His treatise on the "Quadrature of Curves" was published in 1704, more than twenty-eight years after it was written. In 1684, *Leibnitz,* a German philosopher, published an account of his "Differential Calculus" in the *Acta Eruditorum,* an invention so entirely the same as that of Newton, as to differ only in the notation. *John and James Bernouilli,* two eminent mathematicians, uniting their talents to those of Leibnitz, spread this new Calculus rapidly over the Continent, by the solution of many interesting and difficult problems which Geometry had hitherto been unable to solve, or which had been suggested by the new invention itself. In a paper on the line of *swiftest descent,* presented by De Duillier to the Royal Society in 1699, the author remarked that Newton was the first inventor of the New Calculus, and insinuated that Leibnitz had borrowed the invention. This remark lighted up a flame which a whole century was scarcely sufficient to extinguish. A war of problems was now declared in the republic of science, between the English and the Continental mathematicians, which was carried on with much asperity on both sides, though the inventors themselves, especially Newton, took little or no share in the disputes. The English being at that period less skilful in the new Analysis than their opponents, were frequently worsted, and it was only when Newton himself condescended to answer their problems, that a victory was gained.

Taylor. A problem respecting the *Brachystochrone,* or line of swiftest descent, proposed in 1697, as a trial of skill between the contending parties, was resolved only by the most distinguished mathematicians —Newton, Leibnitz, the Bernouillis, and De l'Hospital. Newton's solution appearing in the Philosophical Transactions without a name, drew from John Bernouilli the exclamation, "*Ex ungue leonem!*" The problem of *Orthogonal trajectories,* proposed by Leibnitz in 1716, as a defiance to the English mathematicians, was solved by Newton within a few hours after he received it, on his return from the Mint, fatigued with the business of the day. *Brook Taylor,* one of the ablest geometers of that period, published his "Method of Increments" in 1715, and involved himself deeply in this war of science, though with more success than the unfortunate Keill. A single analytical formula in his treatise, conferred on him more celebrity than the most voluminous works are generally found to bestow. If any one proposition could be said to comprehend in itself a whole science, it was the *Taylorian Theorem;* for from it almost all the truths and results of the New Calculus might be deduced, and by its intrinsic merit that science was speedily established all over Europe.

Optics. The knowledge of Optics which existed previous to the invention of the telescope, was too inconsiderable to form a separate body of science. An important step was made by *Baptista Porta,* in 1560, who invented the *Camera Obscura.* In 1604, Kepler added to the glory of discovering the true laws of the planetary system that of first analyzing the whole scheme of nature in the structure of the eye. Antonio de Dominis, in 1611, had the good fortune to give the first satisfactory explanation of the phenomenon of the *Rainbow. Snellius,* the first of the moderns who measured a terrestrial degree, discovered the true law of *Refraction,* which was first published by Descartes, in 1637. *Gregory,* in his "Optica Promota," which appeared in 1663, gave the construction of the *Reflecting Telescope. Huygens,* a genius of the highest order, in his "Dioptrics," greatly improved the science by a developement of the practical rules for the construction of telescopes, as well as of the causes of the aberration of spherical lenses and of the theory of single and double refraction. Optical researches had begun to acquire a peculiar interest from the discoveries gradually revealed by the invention of the telescope and microscope, when *Newton* entered the field and made all those achievements his own, for which they had prepared the way. The unexpected delight which he felt when, in the course of his experiments with the glass prism, he beheld the brilliant colouring of the sun's image thrown on the wall opposite the entrant ray, may be easily conceived. The elongation of the *spectrum* by refraction, and its divergence into the seven primitive colours, disclosed to him the loveliest of Nature's wonders, and first

"Untwisted all the shining robe of day."

The decomposition of Light thus effected, made known the texture of the magic garment which the Deity had so kindly spread over the surface of the visible world, and which is figuratively said to envelope his throne with beams of insupportable brightness. The Rainbow, that beautiful emblem of his mercy, which has equally attracted the attention of the peasant and the philosopher by the brilliancy of its colours, naturally presented itself to the analysis suggested by this discovery. Accordingly, Newton completed the explanation of the machinery which nature employs in the construction of this splendid arch, which had been left unfinished by De Dominis and Descartes, and gave an example of one of the happiest applications of theory which Science affords. The optical researches of Newton form the noblest commentary on the philosophy of Bacon; an individual of moderate talent, with the "Novum Organum" in one hand and the "Optics" of Newton in the other, could not fail to become a philosopher. To see the genius who had risen by his discoveries to such an extraordinary elevation above mankind, descending to the fabrication of soap-bubbles, might excite the risible faculties of the ignorant and unthinking; but, in the eye of philosophy, no toy is esteemed despicable, and no occupation frivolous, which can assist in the investigation of truth. The explanation of the law of Refraction, on dynamical principles, is another instance of the sagacity of Newton, in whose hands light became also the means of making important chemical discoveries respecting the internal constitution of bodies. The increase of refracting power in inflammable bodies, led him to the fine conclusion that bodies of this nature enter into the composition both of the diamond and of water,—a truth confirmed by the subsequent discoveries in chemistry. These discoveries, in addition to his elegant speculations on "Fits of easy transmission and reflection," excited, by their brilliancy and novelty, the admiration of his most enlightened contemporaries, and at the same time created a host of opponents both in this country and on the continent. The latter, however, were either soon silenced, or forced to join in his praise. Newton perfected the construction of the Telescope, and concluded his Optics with those remarkable queries which, penetrating into the region of future discovery, and soaring beyond the limits of poetical fancy, with those of probability still in view, enabled him to alight safe on the *terra incognita sed firma* of philosophic truth.

Physics. The establishment of Academies or Philosophical Societies, about the middle of the seventeenth century, now contributed greatly to the progress of physical science. The Florentine Academicians, who set the first example in 1651, greatly extended our knowledge of nature, and were followed by the Royal Society of London, which was founded in 1662, and the Royal Academy of Sciences at Paris, which was established in 1666, under the enlightened administration of Colbert. The foundation of Observatories, which apparently served only to carry the views of man beyond the boundaries of the world, proved of the greatest advantage to Navigation, and consequently of Commerce and the arts of life. The observatory at Paris was founded in 1667, and that at Greenwich in 1675. About the era of these establishments, Astronomy was enriched by some of its most brilliant discoveries. *Gassendi,* in 1631, first observed the transit of Mercury over the disk of the sun, which had been predicted by Kepler, and *Horrox,* in 1639, first observed that of Venus. *Huygens,* the great successor of Galileo, about this period acquired, by his discoveries, a degree of fame which was only eclipsed by that of Newton. He improved the telescope, and was the first who explained the beautiful phenomenon of the ring of Saturn, which had baffled Galileo. He discovered one of the satellites of Jupiter, other three being afterwards added by Cassini. He was the first who applied the pendulum to clocks, and showed its utility in astronomy. The laws of the collision of bodies, which had been mistaken by Descartes, were discovered and explained by Wallis, Wren, and Huygens, about 1669. The improvements which the latter philosopher introduced into the doctrine of pendulums were of a remarkably beautiful nature, and constituted the most difficult mechanical inquiries previous to the invention of the new Calculus. The theory of central forces unfolded by Huygens, forms a brilliant link in that noble chain of discovery which led Newton to the explanation of the great phenomena of the universe. This immortal genius laid the top-stone of his fame by the publication of his *Principia* in 1687, an era for ever memorable in the annals of Science. This work, which confers more glory on its author, than the achievements of an Alexander or a Cæsar, compressed the beautiful laws of Kepler into the single Principle of Attraction, and showed that the law of this force, which was the common bond of union in the planetary system, varied inversely as the square of the distance. One of the most remarkable results contained in the Principia, was the method of determining the quantities of matter and densities of the planets, investigations so recondite that they seemed the farthest removed beyond the sphere of human knowledge. The principle of universal Gravitation was found to afford the only solution of the irregularities of the moon's motion that were known, and of all those discovered afterwards which related not only to that body, but to other bodies in the system. The same penetration which enabled its author to range through the celestial spaces, taught him to define the true figure of the earth, and to calculate the tides of the ocean. The cause of the precession of the equinoxes, the true form of the orbits of comets, the properties of water and air, the motion of currents and the propagation of sound, were all brought under the dominion of this amazing genius. Newton had the singular good fortune to enjoy during his life, and in his native country as well as abroad, that high respect and admiration to which he was entitled by his sublime researches and discoveries. He was successively elected Parliamentary representative of the University of Cambridge, Master of the Mint, and President of the Royal Society. Since his death, which happened in 1727, at the advanced age of 80 years, eulogy has been exhausted in tributes to his memory, and Europe has been filled with rivals in his praise. In extent and refinement of mathematical skill, he had no compeer, and the testimony of recent writers, of the highest eminence declares, that he must have discovered certain improvements in the higher analysis unknown even to Euler, and to every mathematician before Laplace. In the study of Nature and her laws, and in the investigation of her analogies and resources, he seems to have been inspired, as it were, with wisdom from an invisible source, and to have been enabled, by a kind of prophetic sagacity, to discover many noble truths which were still veiled in the impervious gloom of futurity. To him, therefore, as intellectual representative of the human race, may be justly applied, that fine saying of Suidas, which inspired Bacon with his figurative appellation of man: "Της φυσεος γραμματευς ἠν, τον καλαμον ἀποβρεχων εἰς νουν."

Newtonian Philosophy. The spread of the Newtonian Philosophy was for a few years retarded by the doctrines of Descartes and his followers, but at last their splendid and imposing fabric was sapped to the foundation, and the immortal structure of Newton, founded on the eternal basis of Geometry, raised in its stead. The mensuration of a terrestrial degree within the arctic circle, and another at the equator, between 1736 and 1742, affording a comparison of results conformable to the Newtonian theory of attraction, completed its triumph on the continent, and forced Cassini and others who had opposed its progress, to become converts to the New Philosophy. The discoveries of Cassini in Astronomy, led to another more remarkable for its singularity and minuteness than any that had yet occurred in the progress of that science. This was the *Velocity* with which *light travels* through space, discovered by Olaus Roemer, a Danish astronomer, in 1667, who offered this as the explanation of the periodic inequality in the eclipses of the satellites of Jupiter, proved his conjectures by calculation, and immortalized his name by the discovery. *Cotes*, the friend of Newton, who signalized himself by his discoveries in the new Calculus published in his profound work the Harmonia Mensurarum, cultivated the doctrine of Hydrostatics with great success. *Dr. Halley*, to whose liberality and enthusiasm the world first owed the publication of the Principia of Newton, was a most assiduous and indefatigable observer of nature, and he has laid science under great obligations. The natural history of the atmosphere, of the ocean and of magnetism, can furnish proofs of his skill as a philosopher, and both Navigation and Astronomy were enriched by his labours. He predicted the return of the comet of 1759, ascertained the nature of evaporation on the vast scale of nature in the Mediterranean, and accounted for the origin of fountains and many other natural and meteorological phenomena. In 1701, he published his Variation Chart, so valuable to navigators at that period and for many years afterwards, and gave the first probable theory of that unknown power which causes the Magnetic needle to deviate from the true North. His observations on this subject were indeed the germ of more recent and important discoveries in the history of Magnetism. The Copernican system of the world, which had been so irrefragably established by Newton, was destined to receive another confirmation as remarkable as it was unexpected. The discovery of the *Aberration of the fixed stars*, in 1726, presented the most complete demonstration of the velocity of light and of the motion of the earth in its orbit, which had yet been afforded by the delicacy of modern researches, and placed the name of Dr. Bradley high in the scale of renown. This celebrated astronomer made another discovery no less important than the preceding, namely, the *nutation of the earth's axis*, which completed the explanation of the cause of the precession of the equinoxes, developed in the Celestial Mechanics of the great founder of Physical Astronomy. The philosophy of Newton assumed a more popular form than it possessed in his great work, in the writings of Clarke, Pemberton, Maclaurin and Musschenbroek, and in the lectures of S'Gravesande and Desaguliers, while its more refined investigations were extended and improved by Maclaurin and Simpson in this country, and by Herman, D. Bernouilli, Euler, Clairault, and D'Alembert on the continent. Maclaurin, Bernouilli, and Euler had the honour of sharing with each other the prize proposed by the Academy of Sciences at Paris, in 1740, for the best Essay on the Causes of the Phenomena of the Tides.

Euler, who was born near Basle, in 1707, was one of the greatest mathematicians of which the eighteenth century, so rich in genius, can boast. He invented *Analytical Trigonometry*, a Calculus no less important than that of Newton, not only for its utility in the higher Geometry, but for its beautiful applications in Physical Astronomy. He subjected to the analytical method, which had now left the ancient Geometry at an infinite distance, the theory of rational mechanics, the whole range of physical astronomy, the vibrations of elastic and incompressible fluids, naval architecture and tactics, the doctrine of chances, probabilities, &c. and made such admirable additions, improvements, and inventions, that of him it might be truly said, with respect to these sciences, "nunquam tetigit, quod non ornavit." France, a country so renowned for splendid genius, produced, about this period, two of her most eminent men to divide the conquests of science, which were beginning to shed a glory over the middle of the eighteenth century, unparalleled in the history of human knowledge. *D'Alembert*, who was born in 1717, made an improvement in the Integral Calculus, which doubled its power and extent. This was the invention of the method of *Partial Differences*, which was afterwards improved in form and notation by the great Euler. *Clairault*, born two years later, commenced a career equally splendid by the publication of his treatise on "Curves of Double Curvature," at the early age of sixteen. These three great geometers, than whom there did not exist at that period a more noble triumvirate, had studied in the schools of Newton and Leibnitz, and having greatly improved the methods of their masters, began, nearly about the same time and unknown to each other, to attempt the solution of the famous problem of the *Three Bodies*. The result was the greater perfection of the Lunar Theory, and the subsequent advantage to Navigation. The solution of Euler furnished data for the accurate tables of Tobias Mayer of Gottingen, which were rewarded by the Board of Longitude in England. Euler also constructed a set of accurate tables from his own theory, which were rewarded by the Board of Longitude in France.

Lagrange. Splendid as the achievements of these great mathematicians appear when compared with the efforts of their predecessors, they sink in the scale of invention before the towering ascent of Lagrange. Born at Turin in 1736, he commenced his illustrious career by an addition to the integral calculus, denominated the *Calculus of variations.* Euler, though he stood at the head of mathematical science, with that generosity and nobleness of mind which are always the characteristic of supereminent talents, was the first to hail the appearance of the young mathematician with joy, and to celebrate his fame by pointing out his merits and adopting his method in preference to his own. This is indeed an instance of the intellectual sublime rarely to be met with in the history of the world, while in that of science it stands without a parallel. The publication of the *Mecanique Analytique* constituted an era in the progress of human knowledge, which even the sagacity of Newton could hardly have anticipated. D'Alembert had discovered the mechanical principle which reduced every question respecting the motion of bodies to a case of equilibrium. This principle was extended by Lagrange, who subjected all problems of this description to mathematical computation, by differential equations, whereby their solution was reduced to the integration of such equations. The singularity of this treatise, besides its profundity and excellence, may be remarked. In this treatise there is no reference made to figures, notwithstanding the great number of mechanical problems which are resolved. The resolution of all the forces that act on a point, into three forces acting at right angles to one another, enables the author to express their relations sufficiently distinct, without representing them by a figure, or by any other symbols than those that are algebraic. The perfection of Physical Astronomy was now approaching. The theory of the disturbing forces of the planets had been successfully cultivated by Euler and his compeers. He proved that the change which had been discovered in the obliquity of the ecliptic was periodical. Yet the secular inequalities in the motions of Jupiter and Saturn were not satisfactorily accounted for; geometers began to push their investigations to the extreme, when Lagrange arose on the eve of discovery and effected one of her noblest achievements. Struck with the circumstance that the calculus had always brought out periodical inequalities, he pursued the study of the general question, whether, in the solar system, those inequalities which continually increase or diminish, and consequently affect the mean motion of the planets, can ever be produced by their mutual gravitation. He found that the inequalities produced by the mutual action of the planets, must in effect be all periodical; and that amid all the changes which arise from this cause, two things remain perpetually the same,—the *mean distance,* and the *mean motion* of each planet. Variations occur in the plane of the orbit and in the nature and eccentricity of the ellipse, but never in its greater axis, nor in the time of the entire revolution of the planet. "The discovery of this great principle, which," as Playfair says, "we may consider the bulwark that secures the stability of our system, and excludes all access to confusion and disorder, must render the name of Lagrange for ever memorable in science, and ever revered by those who delight in the contemplation of whatever is excellent and sublime. After Newton's discovery of the elliptic orbits of the planets, Lagrange's discovery of their periodical inequalities is, without doubt, the noblest truth in Physical Astronomy." This immortal genius, whose mathematical skill surpasses eulogy, had the glory of being the first to remove the difficulties which had clouded the entrance to the New Calculus since the period of Newton, and by his invention of the *Theory of Functions,* to place the noble pyramid of science, reared by the labours of genius, on a firm and immoveable basis.

Laplace. By the efforts of the illustrious astronomers Clairault, D'Alembert, Euler, Lagrange, and Laplace, it was found that, at the close of the eighteenth century, there did not remain a single phenomenon in the celestial motions that was not explained on the principle of Universal Gravitation. To complete the theory of Astronomy, and to compress into one system the entire compass of that science and its discoveries during the most brilliant period in the history of the race, required the genius of another Newton, and this was found in the person of *Laplace.* His treatise entitled the *Mecanique Celeste* fulfilled this arduous undertaking, in a manner that does honour to science and to man, and left nothing more to wish for in this department of human knowledge. We deeply regret that our limited space prevents us from doing justice to the transcendent merits of this immortal astronomer, whose honour is, that the "genius of the human race is the only rival of his fame."

In the perusal of a Dictionary of Arts and Sciences, the reader is generally guided by his own taste and inclination, or by the particular line of his professional or other pursuits, without attending much to any didactic plan that may be proposed in an introduction. A scheme of the contents of such a work, however, adapted to a regular method of study, and expanded according to a natural order, may be of great service to those who have never enjoyed the advantages of a systematic education. We have accordingly adopted the following arrangement of the branches of human knowledge from the prospectus of the European Review, and classified under its various heads such portions of this Encylopædia as correspond with the plan, which, though far from being complete, is perhaps as perfect as any that has been proposed.

The Sciences, according to their natural arrangement, comprehend:—the Principles of all things—the Elements which these *principles* originate—the Beings which these *elements* form—the Organs which these *beings* develope—the Wants which these *organs* experience—the Signs which these *wants* excite—the Societies which these *signs* produce—the Countries which these *societies* inhabit—the Earth which these *countries* compose—the Planetary System to which the *earth* belongs.

GENERAL HEADS.	PARTICULAR SUBJECTS.	NAMES OF THE SCIENCES, INCLUDING THE FOLLOWING SUBDIVISIONS.
PRINCIPLES	Matter, Space, Motion	METAPHYSICS, Philosophy.
	Extension, Divisibility, Impenetrability, &c.	PHYSICS, or Natural Philosophy.
	Number, Form, Magnitude	MATHEMATICS, Arithmetic, Geometry, Algebra, Mensuration, &c.
ELEMENTS	Atoms	ATOMOLOGY, Acoustics, Optics, Pneumatics, Doctrines of Heat, Light, Sound, Steam.
	Molecules	CHEMISTRY, Electricity, Galvanism, Magnetism.
	Masses	MECHANICS, Statics, Dynamics, Hydrostatics, Hydrodynamics.
BEINGS	Minerals	MINERALOGY, Crystallography.
	Vegetables	BOTANY.
	Animals	ZOOLOGY, Bee, Conchology, Entomology, Erpetology, Helminthology, Ichthyology, Mammalia, Ophiology.
ORGANS	Forms	PHYSIOGNOMY, Phrenology.
	Structures	ANATOMY, Zootomy, Surgery.
	Actions	PHYSIOLOGY.
WANTS	Clothing	COSTUME.
	Food	GARDENING, Agriculture, Brewing, Dietetics.
	Shelter	ARCHITECTURE.
SIGNS	Speech	LANGUAGE, Philology, Rhetoric. POETRY, Novel, Versification. MUSIC.
	Gesture	GESTURE, Games, Recreations, Sports and Pastimes. SCULPTURE, PAINTING, Arts of Design, Engraving, Perspective.
	Writing	LETTERS, SYMBOLS, HIEROGLYPHICS, Printing, Mnemonics, Stenography, Abbreviations, Numismatography.
SOCIETIES	Families	MORALS, Biography, Education, Heraldry, Mind, Miracles, Moral Philosophy, Prophecy, Religion, Schools.
	Cities, Nations	CIVICS, POLITICS, History, Institutions, Missions, Political Economy, Poor, Popery, Population, Revenue.
COUNTRIES	Land	GEOGRAPHY, Polar Expedition, America, Britain, China, Egypt, Europe, France, Greece, Hindostan, New Holland, Ireland, India, Rome, &c.
	Sea	HYDROGRAPHY, Navigation.
	Air	AEROLOGY, Aerostation, Aeronautics, Meteorology.
EARTH	Form, Motion, Effects	COSMOGRAPHY, Geology.
PLANETARY SYSTEM.	Forms, Motions, Influences	ASTRONOMY, Dialling, Horology.

The application of the Sciences to the WANTS of Man, constitute the Arts, which are classed under the following general heads, and particular subjects:

GENERAL HEADS.	PARTICULAR SUBJECTS.	PROFESSIONS, ARTS, TRADES, &C.
MEN	In Individuals	MEDICINE, Materia Medica, Midwifery, Poisons, &c.
	In Societies	JURISPRUDENCE, Laws.
	In Nations	WAR, Naval Tactics.
MATTERS	In Production	AGRICULTURE, Coaliery, Fisheries, Veterinary Medicine, Planting, Railway, Roads, Spirituous Liquors, Water Works, &c.
	In Manipulation	MANUFACTURES, Bleaching, Buttons, Calender, Cards, Cloth, Dyeing, Fireworks, Gilding, Glass, Hats, Horn, Ivory, Metallurgy, Paper, Porcelain, Ropes, Soap, Sugar, Tanning, Turning, &c.
	In Exchange	COMMERCE, Banking, Book-keeping, Measures, Money, Ship-building, Trade, Weights, &c.

Anderson's Institution,
Glasgow, Nov. 18th, 1826.

ENCYCLOPÆDIA EDINENSIS.

A.

A, IS the first letter of the alphabet, in all known languages, excepting that of Ethiopia, in which it is the 13th. The simplicity of the sound of this letter has probably obtained for it the first place in most languages; for, in pronouncing it, the lips are merely opened to allow a passage for the voice.

The letter A has three sounds in the English language: *broad*, as in *call*, *malt*; *open*, as in *man*, *ran*; and *slender*, as in *cessation*, *dedication*.

A is employed as the indefinite article, and then denotes the number *one*, as *a man*, *a tree*, that is, *one man*, *one tree*; and it is also prefixed to plural nouns, as *a thousand*, *a million*; but in such cases, these nouns are considered as one aggregate or whole, although composed of a number of individuals. In the following expressions, A denotes *one*, as five pounds *a* week, *a* man, *a* head, or *one* week, *one* man, &c.

A is regarded, by some grammarians, as a substitute for the prepositions *at* or *on*, in such expressions as the following, *a* foot, *a* head, *a* sleep, Thomas *a* Kempis, I am *a* doing, I go *a* hunting, this part is *a* wanting; but when prefixed to the participle, it is clearly redundant.

A was employed by the ancients as a numeral letter, denoting 500, and with a line on the top $\bar{A}$ 5000.

A is used as an abbreviation for many words; as, A. D. anno domini, *year of our Lord;* A. M. anno mundi, *year of the world;* and when preceded by a person's name, artium magister, *master of arts.*

AA, is the name of several small rivers in Switzerland, of some in Germany, of some in Holland, and of one in France.

AAIN-CHARIN, a village near Jerusalem, which is chiefly remarkable for a convent built on the spot where John the Baptist is supposed to have been born. This convent is distinguished for its extent and elegance, and is the frequent resort of pilgrims.

AALBORG, or AALBOURG, a diocese or province of Denmark, and in the northern part of Jutland, is nearly an island, is about 90 miles square, and contains about 81,000 inhabitants.

AALBOURG is also the name of the capital of the above diocese, and signifies *Eeltown*, from the great abundance of eels in the neighbourhood. It is one of the finest cities of Denmark, the population exceeds 1[illegible],000; the trade in herrings and corn is considerable, as well as the manufacture of gloves, saddles, and fire-arms. N. Lat. 57. 3. E. long. 9. 56.

AAM, or HAAM, a Dutch liquid measure, equal to 288 English pints; containing 128 mingles, each weighing nearly 36 ounces avoirdupois.

AAR, is the name of a river in France, and of one in Switzerland, both of which fall into the Rhine.

AARBERG, a town of Switzerland, in the canton of Berne, situated on an island formed by two branches of the Aar, and 12 miles N. W. from Berne. It is also the name of another town in the same canton, and on the same river, distant from Berne 27 miles N. N. E.

AARHUUS, or AARHUSEN, a city and sea-port of a diocese of north Jutland in Denmark, situated in a plain between the lake Guden and the sea. The town has a considerable trade, a population of nearly 15,000, is the seat of an university, and lies in N. Lat. 56. 10. E. Long. 10. 23. The diocese of the same name is 60 miles long and 30 broad, and contains 118,000 inhabitants; the soil is fertile, the country is covered with woods, and its numerous bays, lakes, and rivers abound with fish.

AARON, the high-priest of the Jews, and elder brother of Moses, was specially appointed, by the divine command, to the priesthood among that people. In the deliverance of the Jews from Egyptian bondage, Aaron acted as interpreter to Moses, both in his communications with Pharaoh and his own countrymen. Accompanied by his two sons, and seventy elders of the people, he proceeded half way up Mount Sinai, and remained there, while Moses ascended to the top to receive the law. During this period, Aaron, influenced by the importunities of the people, or fearing their resentment, permitted the golden calf to be set up and worshipped. This happened in the third month after the departure of the Israelites from Egypt. For this sin he was reproved by Moses, and was again admitted to the favour of God; for, in the first month of the following year, he was constituted high-priest, and continued in that sacred office during the remainder of his life. As he was precluded from entering the Holy Land on account of his former distrust of the promises of God, he died in the 123d year of his age, in the 40th year after the departure of the Israelites from Egypt, and was buried in a cave of mount Hor. Aaron died A. M. 2522, and 1452 years before the Christian era.

Aaron, a physician of some celebrity at Alexandria, who wrote a treatise in the Syriac language, on the practice of medicine, before the year 620; and who first distinctly described the small pox and measles, which diseases are supposed to have been introduced into that city when it was taken by the Arabs. A few fragments only of this work are now extant.

Aaron Ben Aser, a learned rabbi, who flourished about the fifth century, and to whom the invention of points and accents in the Hebrew language is ascribed.

AB, is the eleventh month of the civil year of the Hebrews, and the fifth of their ecclesiastical year. It consists of 30 days, and includes part of July and August. The ninth day of this month is observed as a solemn fast among the Jews, on account of the destruction of the temple, which was burnt, first by the Chaldeans, and afterwards by the Romans, both these calamitous events happening on the same day of the year; and it is not a little remarkable, that the edict issued by Adrian, for the exile of the Jews from their native land, was published on the same day of the month.

ABACINARE, a barbarous punishment, which is noticed by writers of the middle ages, and which was inflicted on criminals, by holding a bason of melted metal before their eyes.

ABACK, is a sea-term, expressive of the sails of a ship lying flat on the masts, in consequence of a sudden change of the wind, or of the ship's course, for the purpose of giving the vessel *stern-way*, or of moving backward. In such cases, a ship is said to be taken aback.

ABACUS, the name given to a smooth table covered with sand or dust, on which the ancient mathematicians traced diagrams, and conducted calculations. It is derived from a Phœnician word, *abak*, signifying dust.

Abacus is likewise the name of an instrument for arithmetical operations, and is variously constructed in different countries. In the European abacus, parallel lines are drawn at the distance of twice the diameter of the counters employed. A counter placed on the lowest line, denotes one; on the second line, ten; on the third, 100; and on the intermediate spaces, the counters express one-half of the value of the line immediately above. In the following diagram, the number 1815 is set down both ways.

1000	——O——	——O——	1000
		O	500
800	-O-O-O-O-O-O-O-O-	—O-O-O—	300
10	——O——	——O——	10
		O	5
5	——O-O-O-O-O——	————	

The Roman abacus had pins which were moved in grooves. In the Grecian abacus, brass wires, strung with ivory balls, were stretched on an oblong frame; and of a similar construction is the abacus or shwanpan of the Chinese, which that ingenious people employ with great dexterity in their computations. But, however commodiously constructed, it is obvious, that the general knowledge of written characters, and the use of figures, must supersede such an instrument, and render its description a subject of mere curiosity.

Abacus, or Abaciscus, in *Architecture*, is the highest part or member of the capital of a column, differing in its form in the different orders. See Architecture.

ABADDON is the name which is given by St John, in the Revelations, to the king of the locusts, the angel of the bottomless pit. The word is explained by the inspired writer, and signifies a *destroyer*. Some suppose the angel king to be Satan; and the locusts are understood to be zealots or robbers who infested and laid waste the land of Judea, before Jerusalem fell into the hands of the Romans: while, according to others, Abaddon may have a reference to Mahomet, or to the Serpent Deity, which was anciently the object of worship.

ABANO or Apono, Peter de, a celebrated philosopher and physician, was born in 1250, at Abano, a village near Padua in Italy, from which, according to the fashion of the times, he derived his name. At an early age he went to Constantinople, where he was instructed in Greek, and afterwards studied mathematics and medicine at Paris. Having travelled into different countries, he returned to Italy; was appointed, in 1302, professor of medicine at Padua, which situation he soon resigned, and settled at Bologna as a physician, where his reputation, if it can be correctly appreciated by the magnitude of his fees, rose so high, that for every visit to a patient without the walls of the city he received 50 crowns; and when he attended the pope at Rome, he demanded 400 ducats a-day.

Abano wrote several treatises on astrology, a subject which, with the learned of the times, he seems to have studied deeply, was regarded by the vulgar as a magician, and was supposed to be indebted for his great knowledge to seven familiar spirits, whom he kept confined in a glass vessel. His learning drew upon him the suspicion of the inquisition. He was charged with heresy by that vigilant tribunal, but was acquitted. The charge was repeated when he had reached the 88th year of his age, and death only saved him from a cruel punishment; for the sentence of condemnation was pronounced, and his body was ordered to be raised from the grave and committed to the flames; but being removed by his friends, the sentence could not be farther executed than by burning him in effigy, and this mark of resentment was exhibited in the market-place of Padua. The works of Abano on astrology, scholastic philosophy, and medicine, are numerous and voluminous; but in an age in which some of these studies are exploded, and more enlightened views prevail on the subject of others, they will be rarely consulted.

ABARIS, denominated the Hyperborean philosopher, is supposed to have been a celebrated sage of antiquity, whose history and character, obscured with innumerable fables and conjectures, have been a most fertile subject of learned discussion from the time of Herodotus almost to the present day. Abaris is represented as travelling with an arrow, on which he sometimes took a flight through the air, and as requiring no kind of food; as having visited various parts of Greece, and particularly the city of Athens, to which he was sent ambassador to invoke the prayers of the Athenians, or to assist in some religious ceremony, for the purpose of averting a dreadful plague which then infested the earth. It is said by some that he had an interview with Pythagoras in Italy, was highly favoured by that philosopher, and admitted to the peculiar secrets of his doctrines; while by others he is regarded as a conjurer, or an impostor. Of the native country of this renowned subject of historical criticism, opinions and conjectures have not been less numerous. Some authors assert that he was a native of Scythia, was one of the priests of the Hyperborean Apollo, and when he returned from his travels he presented the gold which he had collected to that divinity; and others, from some peculiarity in his dress, are induced to believe that he was a Druid, and a native of the Hebrides of Scotland. The period when this celebrated personage lived is not fixed by his biographers; and indeed it may be doubted whether he ever had any real existence. But what we have stated affords a striking example of excessive credulity and useless investigation.

ABASCIA, or ABCASSIA, the northern district of Georgia in Asia, and situated on the coast of the Black Sea, between 43° and 45° N. Lat. and 39° and 43° E. Long. The inhabitants, who are generally poor, and charged with being dishonest and treacherous, have some trade in furs, skins, linen-yarn, and bees-wax; but chiefly in female slaves, who are either their own children, or carried off by force, and who being esteemed handsome and beautiful, are in great demand among the Turks, to whom they are usually sold.

ABATIS, or ABATTIS, in *Military Affairs*, a method of defence resorted to in sudden emergencies, in which felled trees are placed together lengthwise, with the branches pointing outwards towards the enemy, for the purpose of preventing his approach. In defending a pass or entrance, the boughs are sometimes stripped of their leaves and pointed, the trunks are fixed in the ground, and the branches are interwoven. This mode of defence, we believe, was practised by Lord Wellington in the lines of Torres Vedras, which were fortified for the protection of Lisbon, and secured with abattis composed chiefly of trees of Spanish oak.

ABBADIE, JAMES, an eminent Protestant divine, was born at Nay in Berne, about the year 1655, and having received the early part of his education in his native place, studied at the university of Sedan. He resided some time in Germany and Holland, accompanied King William into England, and was appointed minister of the French church in the Savoy in London. He was afterwards promoted to the deanery of Killaloe in Ireland, for which he was no doubt indebted to his writings in defence of the Revolution. But he was a man of distinguished talents. His eloquence in the pulpit was greatly admired; and his memory was so retentive, that he arranged and composed his longest works before they were committed to writing. He died at London in the year 1727. Beside the political tract already alluded to, and some others of the same character, he was the author of several theological works written in the French language.

ABBA, in the Syriac language, signifies a father, and, on account of age, or dignity attached to certain official situations, a superior, as the superior of a monastery. See ABBOT.

ABBAS, the son of Abdalmotalleb, and the uncle of Mahomet; is remarkable for having resisted the pretended revelations of his nephew, regarding him as an impostor and a traitor. But being taken prisoner by Mahomet, and a large sum being demanded for his ransom, he attempted to evade the payment, by pleading that it would reduce him to poverty, and thus dishonour his family. When the new prophet reminded him of the immense wealth which he had concealed at Mecca, Abbas, who thought the transaction unknown, was immediately impressed with the belief of the divine authority of the new religion, or perhaps to save and secure his riches, not only became a convert to its doctrines, but a distinguished military commander in its defence, and one of the first doctors of Islamism, or expounders of the Koran, on every chapter of which he is said to have delivered lectures as his nephew received it from heaven. He died in 652, and his memory is still held in the highest veneration by the followers of Mahomet.

ABBE, is the name given to a class of persons in France, who have received the ceremony of tonsure, which entitles them to certain privileges in the church, although they are not in clerical orders. They are employed as tutors in colleges and private families. Some have risen to high situations in the state, and others have been equally distinguished in literature and science.

ABBESS, the superior of a convent of nuns, possesses similar authority with an abbot, excepting the exercise of spiritual functions, for the performance of which some abbesses have had the privilege to grant a commission to a priest. Some abbesses, too, are exempted from episcopal jurisdiction, and are permitted to be present at confession. An abbess is chosen from her own order, and must be 40 years of age before election.

ABBEVILLE, a town of France, finely situated in a fertile valley watered by the river Somme, and distinguished by the name of *Maiden town*, and the motto, *always faithful*, because every attempt to take it has been successfully resisted. The population exceeds 20,000. The manufacture of woollens of fine quality, and the trade in grain, flax, hemp, and coarse linens, are considerable. The Somme is navigable to the town, which is 15 miles distant from the British channel, and 120 miles N.N.W. from Paris. E. Long. 50. 7. N. Lat. 1. 50.

ABBEY, a monastery, or religious house, under the superintendance of an abbot or abbess. In the original endowment of such establishments, it was the intention of their pious founders to afford a comfortable asylum to those who were desirous of withdrawing from the cares and tumult of the world to spend their days in retirement and devotion. But the accumulation of immense wealth, and the acquisition of extensive territorial possessions, introduced such scenes of luxury and dissipation within their walls, and gave them such power and influence in public affairs, as often excited the watchful jealousy of government, and at last led to their final suppression in Britain. As church-property could not be alienated, and as donations to religious houses had become so frequent, statutes were passed to prohibit gifts *in mortmain*, that is, donations to monasteries and similar establishments; and in grants of lands to laymen, clauses are introduced expressly prohibiting them from disposing such lands to monks or Jews.

It seems scarcely credible that the annual revenue of religious houses in England was estimated, in the time of Henry VIII. at the enormous sum of nearly L.3,000,000 Sterling; too rich a prize to escape the rapacity of that monarch, in whose reign they were suppressed. They met with a similar fate in Scotland a few years afterwards. Their immense wealth and extensive possessions were seized by the crown, or by those ministers and favourites who had sufficient influence to obtain a share.

Abbeys, or monasteries, were the seminaries, as well as the repositories of learning; laymen were appointed in some of them for the instruction of youth, and even the monks themselves sometimes undertook that task; and in those religious houses appropriated to women, the education of their own sex, both in useful and ornamental branches, was conducted with great care. The libraries of monasteries were the only safe places, in turbulent times, for the preservation of historical records; and they were amply enriched with the most valuable manuscripts, which had accumulated for ages, and some of which, on account of the beauty of execution and splendour of embellishment, are greatly admired and highly prized in the present day. The sick and poor were admitted into monasteries as into an hospital; the traveller received gratuitous accommodation; and to persons of better condition in life, who had been visited by adversity and indigence, they offered a comfortable asylum. But whatever may have been the benefits of such establishments, the overgrown wealth which they had acquired, and the great mass of industry withdrawn from the community, required some check:—reformation, it cannot be doubted, was necessary; and yet the indiscriminate destruction which followed must ever be seriously regretted, while their venerable remains seem to moulder slowly under the hand of time, as if intended to hold out to distant ages an awful lesson of the fatal effects of misguided zeal and popular frenzy.

ABBOT, derived originally from the Hebrew, and signifying *father*, is the superior of a monastery or abbey of monks. In the early period of the history of monasteries, the abbots were subject to the bishops or ordinary clergy of the district in which they were situated; but when they became rich and powerful, they assumed the rank of prelates, and many of them succeeded in throwing off their dependence on the bishops. Abbots who exercised episcopal authority were called *mitred* abbots: *crosiered* abbots bore the crosier or pastoral staff. There were also *œcumenical*, or universal abbots; and those who possessed authority over all others, were denominated *cardinal* abbots. In Roman Catholic countries, abbots are distinguished by the appellation of *regular*, who take the vow, and wear the habit of the order; and *commendatory*, who are seculars, but have received the ceremony of tonsure, and are bound to take orders at a proper age.

A great deal of ceremony was observed, and splendid feasts were given at the election and installation of abbots. The Dalmatic or seamless coat of Christ, the mitre, crosier, gloves, ring, and sandals, constituted their public dress; while those who sat in parliament were clothed in rich robes. Not less ceremony was observed at the death of an abbot. His seals were formally broken on one of the steps of the great altar; the body, dressed in his pontificals, with his crosier in his hand, was placed in the middle of the choir, where it lay in state for three days; and, thus decorated, was with great pomp and solemnity consigned to the grave.

In Britain, some of the abbots possessed almost regal power. They had the privilege of coining money, of exporting, duty free, the productions of their own domains, and of trying offenders even for capital crimes. The mitred abbots were lords of parliament; and in England, at one period, twenty-seven abbots, called lords abbots, with two priors, sat in the House of Lords.

ABBOT, George, archbishop of Canterbury, was the son of a cloth-worker, and was born in 1562. He studied at Oxford; in 1597 was chosen principal of University College; in 1599 was promoted to the deanery of Winchester; was associated with those engaged in the translation of the Bible, which was begun in 1604 by the direction of James I.; and was employed in 1608 in a mission to Scotland, to unite the churches of England and Scotland under the same form of government. He was consecrated bishop of Litchfield and Coventry in 1609; in a month afterward translated to the see of London; and in the succeeding year he was raised to the first dignity of the church.

For this unexampled rapidity of preferment, the archbishop was no doubt indebted to the royal favour; and it is alleged that it was obtained by servile flattery, of which the following specimen is recorded, and is here inserted as a literary curiosity. Speaking of the king, he says, "Whose life hath been so immaculate and unspotted, that even malice itself, which leaves nothing unsearched, could never find true blemish in it, nor cast a probable aspersion on it. Zealous as a David; learned and wise, the Solomon of our age; religious as Josias; careful of spreading Christian faith as Constantine the Great; just as Moses; undefiled in all his ways as a Jehoshaphat and Hezekiah; full of clemency as another Theodosius." But it ought to be observed, that this strain of learned pedantry was the accustomed mode of the times in addressing the great; and that the conduct of the archbishop was not always marked by the same complying spirit. For, in a case of divorce at the instance of the Countess of Essex against her husband, the Earl of Essex, which was keenly promoted by the king, the matter being referred to a court of delegates, of which the archbishop was a member, he opposed its validity, and forfeited the king's favour; he prohibited the king's proclamation, permitting sports and pastimes on Sunday, from being read at Croydon; and, in the succeeding reign, he refused to license a sermon preached in favour of a loan exacted by Charles, and was for a time suspended from his functions.

While the archbishop was hunting in 1620, he had the misfortune to kill a game-keeper with an arrow from a cross-bow, which was aimed at a deer. This fatal accident impressed him with deep melancholy; and he made every kind of reparation in his power, by settling a handsome pension on the poor man's widow, and keeping a monthly fast on the day on which it happened. But it was followed by a singular investigation, whether he had not forfeited, by this involuntary deed, his archiepiscopal character; the result of which was a dispensation from the king, declaring him absolved from all its consequences, and fully capable of performing all his archiepiscopal functions. He died in 1633, at the age of 71, and was buried at Guildford, the place of his nativity, where he endowed an hospital with a revenue from lands of L. 300 a-year. None of his writings is entitled to much notice. Robert Abbot, the archbishop's elder brother, also rose to a distinguished rank in the church. He was promoted to the see of Salisbury in 1615.

ABBREVIATION, is the contraction of a word by the omission of some letters, or by the substitution of certain marks; has been much practised by professional persons, as lawyers and physicians; abounds in ancient languages and manuscripts, and is of very frequent occurrence in the writings and inscriptions of the Romans.

ABCEDARIAN, or ABCEDARY, a title given to compositions, chiefly poetical, the different parts of which, or the stanzas, begin with the letters of the alphabet, and are arranged in the same order. Such is the 119th Psalm.

ABDALMALEK, the son of Mirvan, and fifth caliph of the race of the Ommiades, was distinguished from all his predecessors by the greatness of his power and the extent of his dominion, and not less so for having excluded the Greek language and characters from the public accounts, and introduced the Arabic numerals now in very general use; a change, it has been observed, which has in a high degree promoted the most important discoveries in mathematical science. His character has been reproached for extreme avarice. Having reigned fifteen years, he died in 699, and in the 80th year of the Hegira.

ABDALS, a sect of people in the East Indies, who occasionally become so infuriated with fanaticism, as to rush into the streets, and destroy every person of a different religion whom they meet; and if they fall in this mad career, their death is considered highly meritorious, and they are venerated by the vulgar as martyrs for their faith.

ABDERA, a town on the coast of Thrace, and near the mouth of the river Nessus, is only remarkable for the extravagant fables concerning it which have been transmitted from ancient to modern times. The inhabitants are characterised as having been extremely stupid. At one time it is said they were banished from their city by immense numbers of frogs and rats; the grass of the surrounding country is described as being of such a noxious quality, that the horses which fed upon it were seized with madness; and the unfortunate people themselves, after being present at the performance of the Andromeda of Euripides, during a hot summer, were attacked with fever and delirium, under the effects of which they fancied themselves players, and imitating the looks and gestures of the different characters, indulged in violent tragic exclamation. This dramatic delirium, it is added, became epidemical, raged during the whole summer, and was only subdued by the cold of winter. Abdera is now only a small village.

ABDOLLATIPH, an Arabian physician and philosopher, was born at Bagdad in the year 1161; and having made great proficiency in rhetoric, history, and poetry, as well as in the doctrines of Mahommedan theology and medical knowledge, he left his native city in the 20th year of his age, for the purpose of visiting other countries. Having spent a year at Mosul in Mesopotamia, he removed to Damascus in Syria, where he obtained a victory over a celebrated grammarian, in a controversy on some literary subjects.

Abdollatiph, anxious to visit Egypt, found it necessary, for the successful prosecution of this journey, to obtain the permission and protection of Saladin, king of the Saracens, to whose arms that country had yielded, and who was now marching against Palestine for the purpose of expelling the Christians from the Holy Land. When the traveller arrived at the camp before Acre, he found the Saracens bewailing a defeat which they had recently experienced, and the lofty spirit of the Sultan sunk in melancholy, so that he was disappointed of a personal interview. But although he was solicited, with the promise of a pension, to leave the seat of war and return to Damascus, he persisted in his resolution of exploring the wonders of Egypt: and, aided by the munificence of Saladin, and the recommendations of one of his ministers, he received the most cordial welcome when he reached Cairo, and continued, during his stay in that city, to enjoy the esteem and friendship of persons of the highest rank.

Abdollatiph withdrew from the agreeable and instructive intercourse with the great and the learned in Egypt, to present himself before the Sultan, who had concluded a truce with the Christians, and then resided in Jerusalem; and he was received by that prince, who was greatly distinguished by dignified politeness, and munificent liberality in the patronage of science and art, with every expression of esteem for his character and attainments. The Sultan, besides, bestowed upon him a monthly pension, which was increased threefold by his sons and successors, and continued till they were driven from the throne of Egypt and of Syria by the ambition of their uncle; and thus, after a short residence in Jerusalem, the traveller was compelled to revisit Damascus, where his lectures and writings were equally the objects of applause and admiration, while his practice as a physician was extensive and lucrative. But his thirst for knowledge, or his desire of contemplating new scenes, again seduced him from the certain pursuit of fame and wealth. He left Damascus, visited Aleppo, resided several years in Greece, and travelled through different regions of Armenia and Asia Minor. Impressed with sentiments of devotion, he resolved to undertake a pilgrimage to Mecca; and, in the meantime, he felt a strong desire of beholding the place which gave him birth; and with this view, he eagerly journeyed towards Bagdad. But he had scarcely reached his native city when he was seized with an illness, which carried him off in the year 1223, and in the 63d of his age. Of 150 treatises which have been ascribed to the industry of Abdollatiph, only one is known to exist, the *Compend of the History of Egypt*, the manuscript of which was brought to Europe by the celebrated traveller Dr Pococke, and is now preserved in the Bodleian library, in Oxford. Dr White published an edition of this work in the original Arabic, with an elegant Latin version, in 4to, in the year 1800.

ABDOMEN, is that part of the trunk of the body situated between the thorax and the pelvis. See ANATOMY.

ABDOMINAL Fishes, or ABDOMINALES, is the name of the 4th order of fishes, according to the Linnæan classification.

ABDUCTORES, or ABDUCTORS, are such muscles as serve to separate or draw away the parts to which they are attached. Of this description are the muscles which separate the fingers.

ABEL, the second son of Adam and Eve, was a shepherd, and offered, in sacrifice to God, of the firstlings of his flock; while his brother Cain, who was a tiller of the ground, offered of the fruits of the earth. God was pleased with the offering of Abel, but he was displeased with that of Cain. The sacred historian is silent on the cause of this preference, or in what manner the displeasure of God was expressed; but the consequence was, to excite a deadly hatred in the breast of Cain against his brother, whom he invited into the field, and put to death. It seems somewhat unaccountable, that the Greek churches, which celebrate feasts in honour of every other patriarch and prophet, pass over the martyrdom of Abel unnoticed; and among the Roman Catholics, his name was not introduced into the list of saints and martyrs before the tenth century. But he is invoked, in some litanies, for persons who are at the point of death.

ABELARD, PETER, an eminent scholastic philosopher of France, whose story and misfortunes, in conjunction with those of Heloise, the object of his attachment, present a striking feature in the annals of the times, and became the theme of the poet in distant ages, was a native of Brittany, and was born in the year 1079. Possessed of vigorous and active intellectual powers, he discovered, at an early age, those talents which were requisite to make a conspicuous figure in the learning of the schools; and, destined by his father to the pursuit of letters, he was entrusted to the care of Rosceline, a celebrated teacher, and founder of the metaphysical sect called Nominalists. By his own assiduity, and the instructions of this able master, he had acquired, at the premature age of sixteen, that subtlety and quickness of thought, fluency of speech, and facility of expression, which were the necessary qualifications to appear with advantage in the field of disputation. Having visited several provincial schools, in his twentieth year he entered the university of Paris, and placed himself under William de Champeaux, the master, whose reputation at that time stood high. But Abelard was not satisfied to remain long in the humble capacity of a pupil: he ventured to contradict the opinions of his master, and held public disputations with him, from which he frequently retired victorious. This success, while it excited the jealousy of De Champeaux, increased the vanity of Abelard, and roused his ambition to aspire after the higher distinction of appearing as a teacher. At the age of twenty-two, he opened a public school at Melun, ten leagues from Paris, and soon had the gratification of seeing himself surrounded with crowds of scholars. But his restless disposition and insatiable vanity, or perhaps some feelings of resentment against De Champeaux, who had employed all his influence in opposing the establishment of his school, prompted him to renew the contest of disputation; and for this purpose he removed to Corbeil, near Paris. A challenge was offered and accepted; the disputants frequently met in each other's schools; the contest was supported with great ardour in the presence of crowded auditories; and the palm of victory was again assigned to the youthful teacher.

Declining health, the consequence of severe study, required Abelard to withdraw from his labours, and retire for a time to his native country. Returning to Corbeil at the end of two years, he found that De Champeaux had taken the monastic habit, but still continued to teach logic and rhetoric, and to hold public disputations in theology. Abelard returned to the charge, again foiled his adversary, and soon attracted crowds of De Champeaux' scholars, among whom he had the gratification to number the new professor, who had surrendered his chair to the young philosopher. De Champeaux, stimulated by resentment, obtained the appointment of another professor, and thus drove back Abelard to his former residence at Melun. This violent measure was unsuccessful. De Champeaux retired to the country; Abelard returned to Paris and resumed his lectures, which were soon crowded by the pupils of the rival school; and De Champeaux re-appearing on the field, had the temerity to renew the contest, in which Abelard was still victorious.

The promotion of De Champeaux to the see of Chalons, terminated the long-contested struggle between the two philosophers; and Abelard, for want of a rival, or perhaps from his unsettled disposition, resolved to exchange the study of philosophy for that of theology. With this view he repaired to Laon, and placed himself under Anselm, a professor of theology of high celebrity. But although the teacher possessed great fluency of language, he communicated little instruction: "He was," says Abe-

Abelard. lard, " a tree covered with a thick foliage, which pleased the distant eye, but, on a nearer inspection, there was no fruit to be found." Abelard retired from these unprofitable lectures; and in a conversation with some of Anselm's pupils, having expressed his opinion that the explanation of the Scriptures was a task of no great difficulty, he undertook, with one day's previous preparation, to give a comment on any part they should point out. The beginning of the prophecy of Ezekiel was fixed upon; and next morning he delivered a lecture on the passage, which was received with admiration and applause. The lectures were continued, and for several successive days attracted a crowded audience. But the rising fame of the young theologian excited the jealousy of the professors, who prohibited the lectures. Abelard obeyed the prohibition, and removed to Paris, where he opened a school of theology, and commenced with his lectures on Ezekiel, which met with equal applause, and drew multitudes of scholars from every part of Europe.

The eventful period of Abelard's life now approaches. Ambition and vanity have hitherto been the ruling principles of his conduct; and the splendid reputation of an able philosopher and subtle disputant which he had acquired, afforded them ample gratification. Other passions now fill his bosom, and other pursuits occupy his thoughts. In the house of Fulbert, a canon attached to the cathedral church of Paris, Heloise, his niece, a lady of eighteen years of age, greatly distinguished for her personal charms, and no less celebrated for her literary attainments, was at this time an inmate. Abelard saw her, was struck with her blooming beauty, and determined to captivate her affections. Fulbert, who regarded the frequent visits of Abelard as a high honour, was at last prevailed upon, by the offer of a handsome gratuity, to admit him into his family; and such was the canon's confidence in the honour and integrity of the philosopher, that he requested him to undertake the instruction of his niece; a trust which Abelard readily accepted, but, it would appear, for the base purpose of betraying it. An unfortunate amour was the consequence of the familiar intercourse which now commenced between them, and was notorious to all, excepting the unsuspecting Fulbert, whose partiality for his niece, and respect for Abelard, excluded every surmise of impropriety. But when concealment was no longer possible, it is not easy to imagine with what feelings of surprise and resentment he received the news of the fatal discovery. Heloise retired to the house of Abelard's sister, in Brittany, where she was delivered of a son. On condition that the marriage should be kept secret, Abelard proposed to Fulbert to make Heloise his wife. The canon consented; but Heloise, in the wild enthusiasm of romantic love, at first rejected the proposal, preferring to live in the character of mistress with one the laws of whose profession required celibacy. Her consent was at last obtained, and the ceremony was privately performed at Paris. From this time Fulbert treated his niece with harshness and severity, which induced Abelard to remove her from his house, and place her in the nunnery in which she had been educated. Fulbert, suspecting that Abelard's real intention was Abelard. to dissolve a connection which tended to mar his future prospects, and urged by resentment, vowed revenge. For this purpose, he hired ruffians, who entered Abelard's chamber by night, and brutally attacked and wounded him. The ruffians were punished; and Fulbert, beside the confiscation of his goods, was deprived of his benefice. But Abelard's spirit sunk under the misfortunes and barbarity which he had suffered; he resolved to spend the remainder of his days in the shades of a convent, and most ungenerously required Heloise to make a similar sacrifice; nay, even insisted that she should first renounce the world, fearing that, if he were once engaged, she might violate her solemn promise. Heloise obeyed, and took the veil; and, in a few days after, Abelard assumed the monastic habit in the abbey of St Denys.

But the dull routine of a convent was ill suited to the restless ambition of Abelard. Invited by his former admirers and scholars in Paris, he resumed his lectures at a small village in the country, and soon collected a numerous audience. The revival of his popularity excited new jealousies; the dæmon of persecution was let loose against him; and a treatise on theology, published about this time, was condemned as heretical, and Abelard was sentenced to commit it with his own hands to the flames. Dreading the consequences of new charges of heresy, he fled from his persecutors, concealed himself for some time in a convent in Champagne, and was permitted to retire to a solitary retreat, on condition that he should not again become a member of a convent. A vale in the forest of Champagne was the spot which he chose for his retirement; and in 1122 he erected a small oratory, which was dedicated to the Comforter, or Paraclete. When the place of his retreat was known, scholars flocked to him from all quarters; and his rustic college could, in a short time, number not fewer than six hundred pupils. But jealousy again provoked his enemies; and while he was meditating his escape from new persecutions, through the interest of the Duke of Brittany he was elected superior of the monastery of St Gildas, where, although not altogether unmolested, he spent several years of his life.

About this time the convent of Argenteuil, of which Heloise was prioress, was annexed to St Denys, and the nuns, who were charged with irregularities, were dispersed. When Abelard was informed of her destitute situation, he invited her, along with eight of her companions, to accept of the Paraclete as an asylum. During Abelard's residence at St Gildas, the correspondence between him and Heloise took place: and from the letters of Heloise, which discover undoubted marks of genius, learning, and taste, Pope has derived the subject of his " Epistle from Eloisa to Abelard;" a highly poetical composition, although not strictly consonant either to the character and story of Heloise, or to moral propriety. Here too it is supposed Abelard wrote his " Theology," which was pronounced heretical by a council; the judgment was confirmed by the Pope; and he was sentenced to perpetual silence and imprisonment. The interposition of friends, and a

Aberbrothick. submissive apology, procured him a pardon, and permission to spend the remainder of his days in the convent of Clugny. Here, excepting occasional lectures, which he delivered at the solicitation of the monks, his time was chiefly occupied in study and devotion till his death, in 1142, and in the 63d year of his age. His body was sent to the Paraclete to be interred. Heloise survived Abelard twenty-one years, and was buried in the same grave. The following epitaph, which is a model of simplicity, elegance, and characteristic expression, was drawn up at the request of the abbess of the Paraclete to the Academy of Belles Lettres, in 1766, and inscribed on their tomb; which was removed, about the commencement of the revolution, and placed in the National Museum:

Hic,
Sub eodem marmore, jacent
Hujus monasterii
Conditor, Petrus Abelardus,
Et Abbatissa prima, Heloisa,
Olim studiis, ingenio, infaustis nuptiis,
Et pœnitentia,
Nunc, æterna, ut speramus, felicitate,
conjuncti.
Petrus obiit 21mo Aprilis 1142;
Heloisa, 17mo Maii, 1163.

The character of Abelard, after the preceding detail of his life, requires no particular delineation. Excessive vanity, insatiable ambition, a restless and turbulent temper, were its more prominent features; and whatever may be said of the illiberality and caprice of the times, the endless controversies and persecutions in which he was involved must be in a great measure charged on himself. But it cannot be doubted, that he who drew together crowded auditories wherever he appeared as a public teacher, and foiled the ablest masters in the art of disputation, possessed talents of no ordinary kind. The conduct of Abelard towards Heloise was treacherous and base; and the deliberate plan of seduction which he formed and executed, has fixed a lasting stain upon his memory. The ardour and inexperience of youth have been advanced as an excuse for Heloise; and romantic attachment, generosity, and sensibility, have been held up as a veil to human frailty. But if such sentiments have much influence on the female character, its beauty and excellence are surrounded by feeble barriers, and it will not be difficult to find an apology for female indiscretion.—The works of Abelard, which are chiefly theological and controversial, and written in the Latin language, do not merit particular enumeration.

ABERBROTHICK, or Arbroath, a royal borough and sea-port town in the county of Forfar, or Angus, in Scotland, and situated at the mouth of the small river Brothic, from which it derives its name. The early history of Arbroath is chiefly connected with its abbey, the ruins of which afford indubitable proofs of its former wealth and magnificence. King William the Lyon granted the privileges of a royal borough to Arbroath about the middle of the 12th century, and founded the abbey in 1178. The abbey was dedicated to Thomas à Becket, archbishop of Canterbury, was occupied by Tyronensian monks from Kelso, and, by various grants and donations, became one of the richest and most distinguished for its privileges of any in Scotland. The abbot was permitted to assume the Episcopal dress, and to exercise Episcopal jurisdiction; and John, King of England, conferred on the citizens of Arbroath the very unusual privilege of trading duty free in every part of his kingdom, London excepted. The last ecclesiastical abbot of Arbroath was Cardinal Beaton. It was erected in 1608 into a temporal lordship, in favour of the Marquis of Hamilton, afterwards became the property of the Earl of Dysart, and was purchased by Maule of Panmure, in whose family it remained till 1715, when it was forfeited.

The population, manufactures, and trade of Arbroath have increased during a century past. The population in 1801 exceeded 7000, and, including the suburbs, is not less than 9000, who are employed in the manufacture of brown linens, or osnaburghs, and sail-cloth. In the year 1804, the brown linen which passed through the Stamp-office amounted to 1,129,495 yards, and was valued at L.62,097; and in 1809 it amounted to 1,484,425 yards, valued at L.83,454. The annual value of the sail-cloth manufacture is estimated at L.100,000. The British navy is supplied with canvas by ten sail-cloth manufacturers of Arbroath. A tan-work has been also established. The harbour, which was first constructed in the early period of the abbacy, and has of late been extended and improved, is safe and commodious, and admits vessels of 150 or 200 tons. Fifty vessels, from 50 to 150 tons burden, are employed in the London, coasting, or Baltic trade. The principal imports are flax, hemp, tallow, and ashes, from the Baltic. The harbour duties, which, in 1717, did not much exceed L.29, were farmed, in 1807, for L.735. A new town-house, including a prison and public offices, has been lately erected; and a library, established in 1797, is rapidly increasing. N. Lat. 56. 33. W. Long. 2. 34. and about 56 miles N.N.E. of Edinburgh.

Aberdeen. ABERDEEN, County or Shire of, in the north of Scotland, is bounded on the north by the Moray Frith; on the east, by the German Ocean; on the south, by the counties of Kincardine, Angus, and Perth; and by Inverness, Moray, and Banff, on the west. Its greatest length, from north-east to south-west, is between 50 and 60 miles, and the breadth from 25 to 30. The superficial extent is estimated at 1200 square miles, and it is divided into 85 parishes. The western parts of Aberdeenshire are mountainous and rugged, and in many places covered with extensive forests. On some parts of the sea-coast, there are considerable tracts covered with blowing sand, while others are terminated by stupendous rocky precipices. Of this latter description are the Bullers or Boilers of Buchan.

The mountains of Aberdeenshire are chiefly composed of granite; this, indeed, is the prevailing rock through the whole county. The quarries of beautiful gray granite, near Aberdeen, have been long celebrated. The stone dug from these quarries, and annually exported to London, is valued at nearly 9000 Sterling. Limestone is abundant, but the want of coal is a bar to its general use. Some parts of the county afford excellent millstones and blue slate. A vein of manganese, discovered near Old Aberdeen, furnished splendid specimens of that mineral in the crystallized state; but being too hard, or impure, it was found unsuitable for the purposes of the manufacturer. The crystals of smoky quartz, known by the name of *Cairngorum stones*, are found in the alluvial soil, on the sides, and at the foot of the mountains, in the interior of the county. A considerable number of persons is employed, during the summer months, in searching for these stones, as well as for another beautiful mineral of an azure blue colour, and to which the name of topaz has been, perhaps inappropriately, assigned. Some masses of Cairngorum stone have been sold in Edinburgh at from L.40 to L.50. Fluor spar, so abundant in the mining districts of England, as a production of Scotland, appears only in this county; some places of which, also, afford indications of lead ore. The mountains produce many of the rarer Alpine plants of North Britain; and *Linnæa Borealis*, the generic title of which commemorates the father of botany, grows in a wood on the borders of the county, the only spot in which it has been discovered in this kingdom.

The rivers of Aberdeenshire are, the Dee, the Don, the Ythan, the Urie, Ugie, and the Cruden. The principal of these are the first two, which derive their origin from the mountains in the west, traverse the county, nearly parallel to each other, to the eastward, and discharge their waters into the German Ocean; the Dee, at New Aberdeen, where it forms the harbour; and the Don, to the north of Old and New Aberdeen. There are many mineral springs in this county; those of Peterhead, Glendee, and Pannanach, have acquired the greatest celebrity, and are places of chief resort. Aberdeenshire contains a number of the chief seats of the Scottish nobility, as those of the Marquis of Huntley, of the Earls of Errol, Kintore, Aboyne, Fife, Aberdeen, and of Lords Salton and Forbes, besides many elegant residences belonging to private gentlemen. The agricultural improvements, which have been, of late years, introduced into Scotland, by the spirit and activity of many of the proprietors, have made no inconsiderable progress in this county. The late Dr James Anderson, whose ingenious speculations and numerous writings have greatly served to illustrate almost every branch of rural economy, was a native of Aberdeenshire, in which he commenced his researches on these important subjects. The real land rent of Aberdeenshire is estimated at L.133,632 Sterling. The population, in 1755, amounted to 117,000; in 1801, to 123,000; shewing an increase of 6000 inhabitants in the period of 46 years.

The sea-coast of this county abounds with excellent fish, and affords employment to a considerable proportion of the inhabitants. The salmon-fishery on the Dee and the Don is the most valuable, yielding a rent of nearly L.3000 annually, and the produce is stated at L.10,000. The greater proportion of the salmon taken in these rivers is pickled, and exported to the London market. Several ships from Aberdeenshire are employed in the Northern Whale Fishery. The produce of four ships from Aberdeen, in the period of the last seven years, is estimated at L.140,000, and of these from Peterhead, in the year 1813, at L.40,000.

The knitting of stockings and hose was formerly carried on to a great extent; but in consequence of the state of the Continent, during the French revolutionary war, that branch of manufacture had declined. It has since revived, by the introduction of spinning machinery, and is now in a more flourishing condition than at any former period. Machinery for spinning wool was first introduced into Scotland by Mr Baird of Aberdeen. It was erected in 1789, on the river Don; in the year 1799, 4000 lbs. of wool were weekly manufactured by 18 engines. The most considerable work of this kind, in Scotland, is that of Messrs Adam and Company at Aberdeen, which extends to 20 machines, driven by two powerful steam engines; and since the introduction of machinery, superfine broad cloths, equal in quality and price to the best made in England, are manufactured in this county. Carpets also form an article of manufacture in Aberdeenshire. The linen manufacture is considerable; and one of the most extensive establishments in Britain for spinning flax by means of machinery, is situated at Grandholme, on the river Don, two miles from Aberdeen; and, at the same place, there are 16 power looms, or looms for weaving cloth by machinery, which are peculiarly distinguished by elegant construction, and ingenious mechanism.

Among other improvements in this county may be mentioned the construction of two timber bridges; the one over the Don, about seven miles from Aberdeen, on the road to Banff, of a single arch, 109 feet in span, with an elevation of 13 feet, which was finished in 1803; and the other, of two arches, each 71½ feet span, and an elevation of 10½ feet, erected at Grandholme, for the accommodation of the extensive spinning establishment of Messrs Leys, Mason, and Company; and a canal from Aberdeen to Inverury, a distance of 18 miles, which was opened in the year 1807. This canal is from 21 to 23 feet wide, nearly four feet in depth, and cost about L.44,000 Sterling.

Aberdeen, Old and New, two cities in the north of Scotland, each governed by its own magistrates; and the latter is the capital of the county of the same name.

Old Aberdeen is a mile distant from the New Town, and not far from the river Don, over which there is a Gothic bridge of a single arch, of 67 feet span and 34½ feet high, which was built in 1290. Tradition ascribes great antiquity to Aberdeen, as being a place of importance in the ninth century. The bishoprick is said to have been translated from Banffshire in the 12th century; and in 1217, similar privileges with those of Perth are granted to Aberdeen. The cathedral, of which one aisle, still used as the parish church, and two spires, are the only remains, was dedicated to St Machar. The fine library attached to this cathedral was totally destroyed in 1560.

The University, or King's College, was founded in 1494, by Bishop Elphinston, who was lord chancellor of Scotland in the reign of James III., and privy seal in James IV.'s time. The latter monarch claimed the patronage, and hence its name. The buildings of King's College are arranged in a quadrangular form, with an open court in the middle, and they are adorned with a fine tower, which is surmounted with an imperial crown. This seminary consists of a principal and eight professors, and it is furnished with a considerable library. The first principal of this college was Hector Boethius, the historian of Scotland. He was invited from Paris to accept of the appointment, with a salary of 40 merks Scots, or about L.2, 4s. 5d. Sterling. The population of Old Aberdeen, including the parish, exceeds 8000.

Aberdeen, New, the capital of Aberdeenshire, is situated on a rising ground, near the mouth of the river Dee, and seems to have been a place of considerable antiquity, if we can judge from the number of religious houses which were established in it; one of which was erected previously to the year 1214. About the beginning of the 14th century, Aberdeen was burnt by the English; and, in consequence of new buildings being erected, it obtained, according to some accounts, the name of New Aberdeen. The church in the High Street, which formerly belonged to the Franciscans, is said to have been begun by Bishop Elphinston, and finished by his successor Bishop Dunbar. The same Bishop Elphinston also provided funds for building the present bridge over the Dee; the execution of which was superintended by Bishop Dunbar. Many of the streets of Aberdeen are spacious; and the houses, which are built of granite, are elegant. Aberdeen contains numerous public buildings and charitable establishments; as, the town-house, with a handsome spire; the prison, with its square tower, surmounted with a spire; the cross, an octagon building in Castle Street; the poor-house, a large building; the infirmary, which annually admits a thousand patients; and the barracks, erected on the site of a fortification which was constructed by Oliver Cromwell. But the chief building in Aberdeen is Marischal College, endowed, in 1593, by George Keith, Earl Marischal of Scotland. This seminary consists of a principal and eleven professors. The common hall contains some fine paintings by Jamieson, who has been distinguished by the name of the Scottish Vandyke, and was a native of Aberdeen. An observatory, furnished with astronomical apparatus, is connected with this college; and the library, and museum of natural history and of antiquities, are respectable. The number of students, including those of King's College, is stated at between 300 and 400.

Aberdeen has lately received some essential improvements, in opening up two elegant and spacious streets, the one leading to the north, and the other to the south. For the accommodation of the latter, a stupendous arch of cut granite, having a span of 130 feet, 29 feet of elevation, and 40 feet within the parapets, has been erected. The harbour, too, has been greatly improved of late years, and particularly by constructing a pier of 1200 feet in length, at an expence of L.17,000.

The trade of Aberdeen, in tobacco, was at one time considerable. Some merchants are, at present, connected with the West Indies and North America; but its chief imports are from the Baltic; and the exports are manufactured articles of the town and county; fish, pickled pork, and granite from the neighbouring quarries. The population in 1801, is stated at 17,600. N. Lat. 57. 8. W. Long. 2° 8', and 120 miles N. E. from Edinburgh.

ABERDOUR, a small town in Fifeshire in Scotland, and situated on the north bank of the Frith of Forth, is a place of some note in antiquity. A convent of nuns of the order *poor Clares*, was established, and the monks of Inchcolm had the privilege of a burial place in Aberdour. The Earl of Morton and his predecessors have been superiors or lords of the manor since the time of David II. The population is about 1000, who are chiefly employed in the manufacture of coarse cloth.

ABERGAVENNY, a town of Monmouthshire, in England, and situated in a rich and beautiful valley, at the conflux of the rivers Gavenny and Usk, over which is a fine gothic bridge of fifteen arches. A priory was founded here in the eleventh century; and the castle, now in ruins, was frequently the scene of treachery and bloodshed, in the earlier periods of English history. This place, of which the population, in 1801, exceeded 2500, is chiefly known as a considerable market for flannels. It is 143 miles W. from London.

ABERNETHY, John, an eminent dissenting clergyman, was born at Coleraine, in the north of Ireland, in October 1680. His father was a dissenting minister in that place; and being called to England on some public affairs, he left his family to the care of his wife, when young Abernethy was in his ninth year. The disturbances which then existed in that part of the kingdom compelled her to retire, with her family, to Derry; and, in consequence of the sufferings and privations to which those within the walls were subjected during the memorable and disastrous siege of that place, she lost all her children excepting John, who then lived with a relation, whom he accompanied to Scotland. In his thirteenth year, he commenced his studies in the University of Glasgow, where he was admitted to the degree of master of arts. He afterwards studied divinity at Edinburgh. In the year 1708, he was appointed minister of the dissenting congregation at Antrim, and held that situation for twenty years. A controversy having arisen concerning subscription to the Westminster Confession of Faith, he became one of the principal leaders among those who opposed it, and was subjected to the censure of a general synod; and being deserted by many of his congregation, he accepted of an invitation to become minister of a dissenting congregation in Dublin; in which situation he continued for ten years, greatly respected and esteemed. He had been formerly subject to the gout; and in consequence of a sudden attack of that disorder, he died in December 1740, in the sixty-first year of his age.

Mr Abernethy was greatly admired as a preacher. His writings in general are distinguished by liberal and manly sentiments. His discourses on the Divine Attributes have obtained considerable celebrity, and are much read and admired. Several posthumous volumes of his sermons were published by his friends.

Abernethy, a small town in Strathern, a district of Perthshire, in Scotland, and situated on the river Tay, is said to have been the metropolis of the Pictish kings, and also the see of a bishop, afterwards transferred to St Andrews. But this place is now distinguished only by a singular tower, of a circular form, 74 feet in height, and 48 in circumference. These towers are not unfrequent in Ireland. One at Brechin is the only instance of a similar structure in Scotland; but of the purposes for which they were intended, whether as places of confinement, or of penance, as has been supposed, the conjectures of antiquarians furnish no elucidation.

ABERRATION, in *Astronomy*, an apparent motion of the heavenly bodies, or a seeming change in the position of the fixed stars, which is produced by the progressive motion of light, and the annual motion of the earth. This important discovery was made in 1725, by the late Dr Bradley, astronomer-royal. See ASTRONOMY.

ABERRATION, *in Optics*, the deviation of the rays of light, when reflected by a speculum, or refracted by a lens, which prevents them from meeting in the same point, called the geometrical focus, but which are spread over a small space, and produce a confusion of images. There are two species of aberration distinguished by their different causes; the one arising from the figure of the lens or speculum, and the other from the unequal refrangibility of the rays of light. See OPTICS.

ABERRATION, *of a planet*, is the space through which it appears to move, as seen from the earth, during the time that light passes from the planet to the earth. See ASTRONOMY.

ABESTA, or AVESTA, a sacred book of the Persian Magi, which is supposed to be the production of their great founder Zoroaster. This work is a commentary on two of their religious books, called *Zend* and *Pazend;* and these three comprehend the whole system of their religion.

ABEX, a mountainous country of Ethiopia, extending along the coast of the Red Sea, 500 miles in length, and about two in breadth. The soil is sandy and barren, the country destitute of water, and greatly infested with wild beasts, and the forests abound with ebony trees. It is subject to the Turks; and Suakem and Arkeeko are its chief towns.

ABEYANCE, *in Law*, is the expectancy of an estate or possession; as, for instance, lands are leased to one person for life, with reversion to another for years; the remainder for years is said to be in *abeyance*.

ABGAR, or ABGARUS, the name of several kings of Edessa, in Mesopotamia, one of whom has been the subject of controversy among ecclesiastical writers, on account of a letter which he is said to have written to Jesus Christ, requesting him to come and cure a distemper of his feet. This letter, and the answer, according to the assertion of Eusebius, by whom they were translated from the Syriac, were preserved in the archives of the city of Edessa. The authenticity of these letters is denied by some divines, while it is admitted by others of no less respectability.

ABIANS, a wandering tribe of Thracians, or Scythians, who lived chiefly on the productions of their herds and flocks; had no other dwellings than their waggons; assigned the privilege of the cultivation of their lands to others, for a small compensation; and were greatly distinguished for their integrity; in allusion to which, Homer eulogizes them as the most honourable men.

ABIB, originally signifying an ear of corn, is the Jewish name of the first month of the ecclesiastical year, corresponding to the latter part of March and the beginning of April.

ABINGDON, a town of Berkshire, in England, is supposed to be the place called Cloveshoo in the Saxon annals, and contains two churches, several charitable institutions, and a free school. At this place a considerable quantity of malt is made, and transported to London by the Thames, which is here navigable for barges. There is also a manufacture of sail-cloth and sacking. Population, in 1801, was 4356. It is seven miles south from Oxford, and 56 W. N. W. from London.

ABIPONIANS, a wandering tribe of Indians, who inhabit the district of Chaco, in Paraguay, of whom, it seems probable, very inaccurate and exaggerated accounts have been related. They are represented as a bold and independent people, much occupied in hunting and war. They possess many horses; and, in a single incursion against the Spaniards, sometimes carry off several thousands. Polygamy is admitted; and the barbarous practice of destroying their offspring is quite common among the women. The Abiponians, like every other uncivilized people, are greatly influenced by their soothsayers, without whose advice no undertaking is attempted. A singular custom is said to prevail among them. The moment a person expires, he is wrapt up in a hide, and committed to the earth. The hut in which he lived is thrown down; all things which belonged to him, his horses, and other animals, are destroyed; his widow and children remove to a distant country, and every memorial of the deceased is obliterated. The number of this savage people is now reduced, by wars and other causes, to 5000. The attempts of the missionaries to convert them to the Christian faith have not succeeded.

ABJURATION, Oath of, signifies the renouncing and denying the right of the Pretender to the crown of Great Britain.

ABLAI, or ABLAY, a country of Great Tartary, the inhabitants of which are called *Buchars;* are governed by a Calmuck chief, but are subject to the Russian government. This country extends 500 leagues along the southern frontier of Siberia.

ABLATIVE, in *Grammar*, is the sixth case of Latin nouns, to which some suppose there is no corresponding case in the Greek language. It may be said in general to denote concomitancy, which is expressed by the use of *with* or *from* in the English language. There is, strictly speaking, no such thing as the ablative absolute in the language of grammarians; for what has been invariably so denominated, by Ruddiman and others, is nothing more than the expression of a concomitant circumstance. *Sole oriente fugiunt tenebræ*, While the sun rises, darkness flies away. The flying away of the darkness is the result of the rising of the sun; so that the one is a concomitant circumstance of the other. See GRAMMAR.

ABLE, or ABEL, a clergyman who was chaplain to Catherine, queen of Henry VIII. and greatly distinguished himself in opposing the proceedings against her for a divorce. In 1534, he was prosecuted for being concerned in the affair of Elizabeth Barton, called the holy maid of Kent, who announced herself as a prophetess. She was condemned and executed, along with several of her accomplices; and Able being charged with misprision, or concealment of treason, was thrown into prison. He was afterwards convicted of denying the supremacy over the church, which Henry, in his arbitrary manner, had assumed, and strenuously maintained; and he was condemned to be hanged, drawn, and quartered; which sentence was put in execution in Smithfield, in the year 1540.

ABLUTION, a ceremony connected with religious rites, in very general use among ancient nations, and still practised in different parts of the world, consists in washing the whole, or parts of the body, before offering sacrifice, or performing other religious duties. These washings are of remote antiquity; they were enjoined by the Jewish lawgiver, and adopted both by heathens and the followers of Mahomet. They were practised by the Egyptians, Greeks, and Romans, as well as by the first Christians, and they are still observed by Roman Catholics and Mahometans.

ABO, a seaport town, and capital of Swedish Finland, situated on the promontory formed by the gulfs of Bothnia and Finland, and about 120 miles north-east from Stockholm. The town is built on both sides of the river Aurajocki, and has a communication by means of a wooden bridge. The population, in 1791, was nearly 9000. The manufactures are, sail-cloth, fustians, silk ribbands, leather, paper, tobacco, watches, and clocks. The trade is considerable: iron, copper, tar, and deals are exported; and coffee, sugar, wine, salt, grain, &c. are imported. The plantations of tobacco in the vicinity yield annually, it is stated, 152,000 cwt. of tobacco.

The Russians took possession of Abo in 1713, and retained it for seven years. A gymnasium, founded by Gustavus Adolphus in 1626, was converted into a university, by Queen Christina, in 1640, in which are now taught, anatomy, natural history, chemistry, &c. The same queen established the library, which consists of 10,000 volumes, besides manuscripts, ancient coins, medals, &c. The school of anatomy, which is said to be in considerable repute, enjoys a very extraordinary privilege. All persons who hold lands or pensions from the crown, are bound, by a particular regulation, to leave their bodies to be dissected, for the instruction of the students.

ABOLITION, the act of making void, or annulling; and, in our law, the repealing of any statute. When a prince granted liberty to a criminal accuser to give up the farther prosecution of the party accused, it obtained the name of abolition. Civilians employ it to denote remitting the punishment of a crime. It signified, in the *Roman Law*, the annulling of a legal prosecution, and of course differed from an *amnesty*, by which an accusation was extinguished for ever. *Abolition* also denoted the erazing of a person's name from the public list of the accused, which was hung up in the treasury. It was either public or private; the former like that under Augustus, when all the names were expunged at once; or private, when that was done at the motion of one of the parties.

ABOMASUS, or ABOMASUM, names which have been given to the fourth stomach of ruminating animals. It is from the abomasus, or fourth stomach of calves and lambs, that the runnet is obtained, for the coagulation of milk, or its conversion into curd. See ANATOMY.

ABOMINATION, a term employed in Scripture to denote the Hebrews, who, leading a pastoral life, are said to have been an abomination to the people of Egypt, on account of their sacrificing the animals which the Egyptians deemed sacred. The term *abomination* is likewise used in Scripture to denote idolatry, which, being frequently attended with licentiousness, is odious. Antiochus Epiphanes ordered the statue of Jupiter Olympus to be placed in the temple of Jerusalem, which commentators understand to be meant by the phrase of the prophet Daniel, the *abomination of desolation*; and the same expression employed by the evangelists, is referred to the Roman ensigns, during the siege of Jerusalem by Titus, because the representations of their gods were embroidered on them, and placed on the temple after it was taken.

ABORIGINES, in the most limited acceptation of the word, denotes a particular people in Italy, inhabitants of ancient Latium, now known by the modern name of *Campagna di Roma*. According to the opinion of St Jerome, the Aborigines were so denominated as being *absque origine*, the postdiluvian planters of the country; while others are of opinion that they were so called, as being originally Arcadians, who claimed to be born of the earth, and not deriving their origin from any people whatever. In a modern sense, it is employed to denote the original inhabitants of any country, in opposition to colonies, or new races of people from a distant region. Thus, the natives of Britain, in the time of Julius Cæsar, were the Aborigines of that country, in opposition to the Saxons and Danes, by whom it was afterwards subdued.

ABORTION, the premature expulsion of the fœtus. Solon and Lycurgus, the celebrated legislators of Greece, strictly prohibited every attempt to procure abortion. The practice was common among the Romans; and it is doubted whether any prohibition existed against it previously to the time of Antonine and Severus, who made it criminal only in the case of a wife procuring abortion, from resentment, to deprive her husband of the comfort of children. The punishment annexed was only temporary banishment. In the present day, it is a common practice, in different parts of the world. Before the revolution in France, the crime of procuring abortion was punished with death; but since that period, the punishment is twenty years imprisonment; and it ought to be generally known, that, by an act of the British parliament, passed in the year 1803, those who are guilty of procuring abortion, in the early period of pregnancy, or before the child be quick, are subjected to imprisonment or transportation; but in the latter period, or when the child has quickened, they shall suffer death. It is scarcely necessary to add, that, in the case of a woman's death, in consequence of medicines taken for the purpose of causing abortion, those who administer them are chargeable with the crime of murder; for this, it is obvious, must be considered equivalent to the exhibition of poison.

ABOUKIR, a small town between Rosetta and Alexandria, in Egypt; is supposed to be the ancient Canopus. It is built upon a rock, and seems to have been formerly an island. Aboukir is an inconsiderable place, has few inhabitants, and scarcely any trade; but it is celebrated on account of the splendid victory gained by Lord Nelson over the French fleet on the 1st of August 1798, and by a severe engagement between the Turks and French, which took place in July of the succeeding year, when Buonaparte obtained possession of the peninsula. It was taken by the British in 1801. Aboukir is 12 miles N.E. from Alexandria.

ABRAM, or ABRAHAM, in Scripture history, the father of the faithful, was the son of Terah, and the tenth in lineal descent from Shem, the son of Noah. It is supposed that he was born in the city of Ur in Chaldea. Accompanied by his father, Abraham left that city, and resided at Haran, in Mesopotamia, where Terah died. He then received the divine command to go to Palestine, which was inhabited by the Canaanites; and the promise was then made to him, that his descendants should become a great nation, and that a seed should be raised up to him in whom all nations of the earth should be blessed. Under the firm belief of the accomplishment of this promise, he took with him his wife, his family, and cattle, and settled in Canaan. He died at the age of 175 years, and was buried in the cave of Machpelah: but for the particular detail of the life of this patriarch, we must refer to the Scripture narrative by Moses. A great deal of traditionary history has been related of Abraham, little of which is worthy of notice; and it has been added, that he was profoundly skilled in many sciences, and was the author of several books; that he taught the Egyptians arithmetic and geometry, and instructed the Phœnicians in astronomy.

ABRASAS, or ABRAXAS, a mystical, or cabbalistic word, composed of Greek letters, which, according to the Grecian mode of numeration, are equivalent to 365. This word is also supposed by some to be the name of the supreme god of the Basilidian heretics; and that they wore gems, by way of charm or amulet, on which this word was engraven. According to Basilides, the founder of this sect, there are 365 heavens between the earth and the empyrean, to each of which an angel or intelligent being, by whom it was created, is appointed. Each of the angels was created by the superior angel,—thus ascending to the Supreme Being, or the first Creator of all; but of the origin and use of these gems, which have greatly occupied the attention of antiquarians, their opinions are quite unsettled.

ABRIDGMENT, in *Literature*, the reduction of a book into a smaller compass; is an occupation of great utility, both to the abridger himself, to enable him to become master of the contents of any work, and for the purpose of communicating to the public the more essential parts of any subject. The method of reducing the bulky works of the ancients came into general use about the fifth century. Some of those who were engaged in this occupation were satisfied with a mere abridgment of their authors, whose expressions were employed, or only inconsiderable alterations adopted. Some composed abridgments by extracting the materials from various authors, and clothing them in their own language; while others consulted several authors who wrote on the same subjects, took passages from each, and uniting them, formed a new work. The best maxims, the characters of persons, descriptions, and other topics which appeared most interesting, were preserved; and in this way, it is probable, many valuable fragments of antiquity have been rescued from oblivion.

The art of abridging is peculiarly useful, either in committing to memory, or in writing down what is delivered by public speakers; and for this purpose it is necessary that the plan and arrangement of the subject should be well understood, and then it will not be difficult to recollect and note down the leading parts of the discussion, and the arguments which are employed in support of the different topics and positions which are advanced. The abridger may then extend it in the form of a discourse, dressed in his own language, and thus materially improve his talents in composition. In abridging any printed work, the first thing to be attended to is its precise object, and then to study those parts of it which are most essential in attaining the object which the author had in view. When the abridger has reached these points, he is qualified to retrench redundancies, to clear up ambiguous expressions, and even to produce a more perfect work than the original.

ABRUZZO, a province of Naples, and anciently the country of the Samnites, a brave people, who were long distinguished for their successful hostility to the Romans. The Adriatic forms the boundary of this province on the north-east; and the river Pescara divides it into Abruzzo Citerior and Ulterior, of which Aquila and Chieti are the chief towns. The soil in many places is rich and fertile; rice, wheat, and other grain, wine, oil, fruit, and saffron, are abundant; but the want of roads and commodious harbours renders exportation difficult, and excludes the inhabitants from the advantages of an exchange of commodities for their redundant productions, so that they are very generally in great poverty and wretchedness. Liquorice is cultivated on the coast, and the produce of wool is considerable, from extensive flocks of sheep, which thrive well on the pastures of the more elevated regions in summer, and of the warmer plains in winter. A large extent of the province is mountainous and rugged, covered with thick woods, which afford shelter to numerous wolves and bears, whose predatory incursions, during the severity of winter, are often exceedingly destructive. The lynx or tyger-cat, and deer, are enumerated among the wild animals. The manufactures extend only to coarse woollen stuffs and pottery ware, the latter of which finds a ready market in Germany.

To the southward of Abruzzo Ulterior, lies the ancient lake *Fucinus*, now called *Lago di Celano*; and the canal or drain, for carrying off its superfluous waters, traverses this province. This canal was constructed by the Emperor Claudius at an immense expense, 30,000 men being employed for the period of eleven years. The extent of this canal is three miles; part of it is open, part is supported by masonry, and part is dug through a mountain. This lake, which exceeds forty miles in circumference, is described by travellers as a most beautiful and romantic expanse of water; but in consequence of the numerous torrents from the surrounding mountains, which are often swoln with rains or melted snow, its banks were frequently subjected to destructive inundations; and as great part of the canal is now filled with rubbish, the neighbouring plains are still liable to the same calamity.

ABSALOM, in *Scripture history*, the son of David, king of Israel, and the brother of Tamar, who was ravished by Ammon, their elder brother, by a different mother. Two years elapsed before an opportunity offered of revenging this injury, when the assassination of Ammon was perpetrated at a feast prepared by Absalom. To avoid his father's resentment, he fled to Talmai, king of Geshur, and remained with him three years; and he was no sooner restored to favour, than he stirred up the Israelites to revolt against David. Absalom's army was defeated; and in his flight through the wood of Ephraim, his hair was entangled in the branch of an oak tree, where he hung till Joab came up and pierced his body with three darts, although David had issued the most express orders to spare his life. When he heard of the fate of Absalom, he was thrown into the deepest affliction, and the pathetic lamentations which he uttered for the death of his rebellious son forms part of the sacred narrative.

The weight of Absalom's hair, which is stated at "200 shekels of the king's weight," has been a fertile subject of criticism among commentators, arising, no doubt, from the uncertainty of the precise weight of the shekel. According to the estimate of some, it was 6¼ pounds; by that of others, it is increased to the enormous quantity of 12½ pounds; while others reduce it to five ounces.

ABSCESS, in *Surgery*, a cavity containing purulent matter, so denominated from a word which signifies to *separate*, because parts naturally united, in consequence of injury or disease recede from each other by the secretion and accumulation of matter. See SURGERY.

ABSCISSA, or ABSCISS, is the segment of the diameter of a conic section, between its vertex and an ordinate. See CONIC SECTIONS, under MATHEMATICS.

ABSIMARUS, a short-lived emperor of the East, who owed his elevation to one of those sudden revolutions which are effected by the power of an army in unsettled states. He was proclaimed by the soldiers in the year 698. He succeeded Leontius, who, after mutilation, by having his nose and ears cut off, was thrown into a monastery. Justinian II. who had been dethroned by Leontius, aided by the Bulgarians, attacked and took Constantinople, and made Absimarus prisoner. Having both usurpers in his power, he commanded them to be loaded with chains, and while he enjoyed the barbarous satisfaction of standing with a foot on the neck of each of his insulted rivals, for the space of an hour, in the presence of all the people, the air resounded with exclamations from the fickle multitude, who sung, "Thou shalt walk on the asp and the basilisk, and tread on the lion and the dragon." After this cruel treatment, the dethroned monarchs were beheaded in the year 705.

ABSINTHIATED, a term used by older medical writers, and signifying a substance impregnated with wormwood, as wine or spirits, hence called wormwood wine, &c. Infusions of this kind are beneficial in cases of indigestion.

ABSOLUTE, in its general meaning, is expressive of something which is free or independent, which does not subsist in virtue of any thing as its cause, in which sense God is said to be absolute. The same word is employed to denote what is unfettered by conditions or limitations, as in the phrases *absolute obedience, absolute promise*.

ABSOLUTE NUMBER, in *Algebra*, is any pure number in an equation, or the known quantity which forms one of its terms; as in the equation $2x + 12 = 24$, the numbers 12 and 24 are absolute.

ABSOLUTION, in the *Civil Law*, is the sentence pronounced, after hearing the evidence by which a person charged with a crime is declared innocent. According to the forms of the Roman judicatories, when the pleadings were finished, three ballots were delivered to each of the judges: One was marked with the letter A. signifying *absolvo*, I absolve or acquit; another with the letter C. signifying *condemno*, I condemn; and the third, with the letters N. L. signifying *non liquet*, it is not clear, or, the case is doubtful; and the sentence pronounced corresponded to the majority of votes of condemnation or acquittal.

ABSOLUTION, in the *Canon Law*, is that act by which the priest, according to the forms of the Roman Catholic church, pronounces the remission or forgiveness of the sins of those who make full confession, and give evidence of sincere repentance.

ABSORBENT *Medicines*, are such substances as, if taken into the stomach, are supposed to have the property of combining with or absorbing acrid or redundant matters, which are preternaturally secreted in the digestive organs; such are, testaceous powder, or chalk, or crabs' eyes, or magnesia; and certain substances are applied externally to the skin, with a similar intention of absorbing acrid humours which are exuded in cases of inflammation.

ABSORBENT *Vessels*, or ABSORBENTS, in *Anatomy*, are minute and transparent vessels which have been detected in animal bodies, and which take up or imbibe fluids which come in contact with them. These vessels are divided into *lacteals* and *lymphatics*. The lacteals open on the internal surface of the stomach and intestines, and absorb the chyle or nutritious fluid, and convey it to the mass of blood, to repair the waste which it sustains in the course of the circulation. The lacteals derive their name from the fluid which they contain having a milky appearance. The lymphatics are so denominated, from

Absorption.

the lymph, or pellucid fluid, which they absorb and convey from the cavities and surface of the body. See ANATOMY and PHYSIOLOGY.

ABSORPTION, in *Physiology*, the function of the absorbent vessels, or the power by which they imbibe and propel their peculiar fluids. Some have attempted to explain this function, on the principle of capillary attraction, while others ascribe it to the pressure of the atmosphere, or to suction, which is only a different mode of expressing the same fact, since it depends on the same pressure. See PHYSIOLOGY.

ABSORPTION, in *Chemistry*, is that power or property, which some bodies possess, of absorbing or attracting others, in the state of liquid or elastic fluid. Thus, a sponge absorbs a large proportion of water; a piece of wood, or porous stone, exhibits the same property; water combines with different airs or elastic fluids, in proportion to its temperature; and fresh prepared charcoal greedily absorbs air or water. In some of these cases, the absorption is to be considered as a mechanical rather than a chemical action. But the process of slaking lime presents one of the best examples of the absorption of a liquid by a solid body, and is, besides, a case of chemical combination. Here a large portion of water unites with the lime, which falls down in the state of dry powder; and, during the process, great heat is produced in consequence of the evolution of the caloric, or heat which is necessary to retain the water in the liquid form. See ATTRACTION, under CHEMISTRY.

ABSORPTIONS *of the Earth*, an expression which has been employed by naturalists, to denote the sinking of extensive tracts of land, in consequence of subterraneous convulsions. Such absorptions are by no means uncommon in countries which are subject to earthquakes; and few, indeed, which are visited by calamities of this kind, are entirely exempted from their dreadful effects. Examples are not wanting, both in ancient and modern times. Pliny mentions, that the town of Curetes, with the mountain on which it stood, was entirely swallowed up. He records also a similar fate of the city of Tantalus, in Magnesia; and afterwards of the mountain Sypilus. Galanis and Gamalis, celebrated towns in Phœnicia, and the lofty promontory of Phegium in Ethiopia, disappeared, and left not the slightest vestige of their existence.

In more modern times, Picus, a lofty mountain in one of the Molucca isles, which was seen at such a distance as to be a useful landmark to sailors, was shaken by an earthquake, and sunk in a moment. An extensive lake, whose shores marked the limits of the base of the mountain, now occupies its place. In the year 1566, an entire province, in a mountainous district of China, was swallowed up, with all its inhabitants, and what was formerly dry land became an immense lake. Those parts of South America, in which earthquakes prevail, have suffered greatly from similar calamities; and in 1692, during a dreadful earthquake, great part of the town of Port-Royal, in Jamaica, with a large proportion of the inhabitants, sunk into the ocean.

The fall of mountains has been ascribed to a similar absorption of some part of the subterraneous materials which support their base. In the year 1727, a mountain in the south of France, forming part of the chain of the Cevennes, fell, with a tremendous crash, into the valley below, and in its progress overwhelmed an entire village, the inhabitants of which fortunately escaped, in consequence of being at some distance, celebrating a rural festival. But the most memorable calamity of this description took place in Switzerland, on the 3d September 1806, when the Spitzberg, a projecting cliff of the mountain Rosenberg, was suddenly precipitated from the height of 2000 feet, and overwhelmed in its ruins five or six villages, with nearly 2000 inhabitants.

Abstinence.

ABSTINENCE, in its general meaning, is the act of avoiding or refraining from something to which there is a strong natural or habitual propensity. But this word is employed particularly to denote a spare diet, or denying the appetite its full indulgence in certain kinds of food to which it has been accustomed. Many remarkable effects in promoting health, and protracting life, and some wonderful cures recorded by the older medical writers, are ascribed to abstinence. But it must be observed, that the abstinence here alluded to, is confounded with moderation and regular habits of life. Such, for instance, is the example of Cornaro, a noble Venetian, who had lived in dissipation and luxury till the age of forty, when he was seized with a violent disease, which threatened his life, and who, by the mere effect of abstinence, not only recovered, but enjoyed almost unbroken health to the great age of 100 years. But this, and similar cases on record, ought perhaps to be considered in no other light than as striking examples of the beneficial effects of temperance and regularity.

Abstinence is more frequently applied to those cases of animals which are either totally deprived of food, or live on a very small portion. Many animals live a long time under a total privation of food: Such, for instance, are those which become torpid on the approach of winter; but in these cases the animal functions are in a great measure suspended, and are only restored to their former vigour by the genial warmth of spring. The most remarkable examples of abstinence, or total privation of food, are found among the cold-blooded animals, as frogs and toads, serpents, lizards, and insects. A rattlesnake has lived many months without any food, whilst its health and vigour seemed in no degree diminished. Dr Shaw mentions, that two Egyptian serpents, which had been kept five years in a bottle, closely corked, had just cast their skins when he saw them, and were as brisk and lively as when they were first taken. Experiments have been made by Redi, Leuwenhoek, Buffon, and other naturalists, to ascertain how long different animals could live without food. A spider lived eight months; a beetle, three years, when it escaped; a toad fourteen months, and, in another instance, eighteen months; a land tortoise eighteen months; several dogs lived thirty-six days; a wild cat twenty days; a civet cat ten days; a badger a month; an eagle twenty-eight days; and wild pigeons twelve and thirteen days. Even human beings have afforded astonishing examples of living a considerable time under a total privation of food;

as in cases of shipwreck, when the crew had been thrown ashore on desart islands, or when persons have been buried under the snow, or confined in places altogether inaccessible.

Abstinence, as a religious observance, may be considered as either partial or temporary. It is partial, as in the case of the Jews, who abstained from particular kinds of food, according to the ordinances of their law; and on certain days of the week, as well as during the period of certain festivals, the Roman Catholics abstain from eating flesh. On the other hand, during some of the religious festivals among the Mahometans, a temporary abstinence from food is ordained, and they are strictly enjoined to observe it from sunrise to sunset. A similar abstinence was observed among some of the ancient sects of philosophers. The Pythagoreans were forbidden the use of animal food, except what remained of the animals offered in sacrifice. Their drink was pure water, or only a small portion of wine, in which they might indulge in the evening.

ABSTINENTS, a heretical sect which arose in France and Spain about the end of the third century, and are supposed to have derived some of their tenets from the Gnostics and Manicheans. They disapproved of marriage, and prohibited their followers from the use of flesh meat.

ABSTRACT, in its general acceptation, denotes something which is considered apart, or separated from other objects with which it is naturally conjoined.

Abstract, in *Literature*, is a sketch or compendious view of any subject treated in a larger work, but shorter and more condensed than an abridgment.

Abstract, or Pure Mathematics, considers magnitude or quantity generally, or without reference to any particular magnitude or number, as in arithmetic and geometry; and is opposed to mixed mathematics, or the application of mathematical science to the investigation of material objects; as, for example, when the properties of air and light are examined, constituting the sciences of Pneumatics and Optics.

Abstract Numbers, are assemblages of units, considered independent of any reference to particular objects; thus, 4 is an abstract number; but 4 trees is a concrete number, because it is conjoined with certain specific objects.

Abstract Terms, are words which express certain properties or qualities, considered apart from the objects in which they reside; as, brightness, redness, hardness.

ABSTRACTION, is that operation of the mind which is occupied in considering one property or quality of objects separate from others with which it is conjoined in nature. Thus, in the expressions, *red coat*; *red rose, red pink*, a certain quality, denoted by the term *red*, is said to belong to each of these objects. But, by the power of abstraction, the mind separates this property from individual objects, and considers it under the general term *redness*. In the same way, the mind proceeds in arranging and distributing objects possessing some common properties into groupes or divisions, according to colour, figure, density, or degrees of hardness, or some other common property, by which the groupe or division to which distinctive appellations are given, is characterized and known. This is called *generalization*, and is a very important mode of procedure in the acquisition of knowledge; for by this means the labour of investigation is greatly abridged and facilitated. See Logic and Metaphysics.

ABSURDUM, Reductio ad, *leading to an absurdity*, in Geometry, is a mode of demonstration resorted to by mathematicians, to prove the truth of a proposition, by shewing that the contrary is impossible, implies a contradiction, or leads to an absurdity.

ABTHANE, an honorary title of distinction, which existed in the earlier periods of Scottish history, the nature of which seems to be imperfectly understood by antiquarians. According to one explanation, the nobles, or *thanes*, held a middle rank between *abthanes* and *underthanes;* the first possessing a superior, and the last an inferior dignity. But according to another view, the thane, which, in the Saxon language, signifies, *minister of the king*, was appointed to attend to certain rights which the king reserved over lands granted to a bishop or abbot; while the abthane was the minister, or steward, of the ecclesiastical possessor.

ABUBEKER, or Abu-Becr, the immediate successor and confidential friend of Mahomet, was the first convert to the new faith, and his only companion in his flight from Mecca to Medina. He was originally named Abdulcaaba, *servant of the temple.* This was changed to Abdallah, or, *the servant of God;* and when the prophet married his daughter Ayesha, he assumed that of Abu-Becr, the *father of the virgin.* The new religion was in imminent danger of perishing on the death of its founder; an event which was thought by many of his followers to be impossible. But Abubeker, with the assistance of Caled, an able general, prevented a total revolt, and either reduced to submission, or punished with death, all who disputed or opposed his authority. His prudence and moderation powerfully checked the fanaticism of the disciples of Mahomet, after that prophet's decease; and having restored tranquillity within his own dominions, he carried his victorious arms into Syria. His celebrated general, Caled, laid siege to Damascus; and on the very day on which it capitulated Abubeker died, in the 64th year of his age, and 13th of the Hegira, and 635 of the Christian era.

Abubeker was distinguished as caliph (the name which all his successors assumed) for his prudence, equity, and moderation; for his indifference to riches and honours; his liberality to the poor, and to the military, among whom he divided his revenue. He collected the detached revelations of Mahomet, to which the Arabians gave the name of *Almoshaf*, or the book, the transcript of which was deposited with Hassa, the widow of Mahomet.

ABULFARAGIUS, Gregory, a native of Malatia, a city of Armenia, was born in 1226. He followed the profession of his father, which was that of a physician, but was afterwards created bishop of Guba, by Ignatius, patriarch of the Jacobites. He was a voluminous writer; but his Epitome of Universal History, which was published in 1663 by Dr Pococke, with a Latin translation, is considered as the most learned and valuable of all his works. He was well acquainted with the Greek, Syriac, and Arabian languages; and he was panegyrised by his cotemporaries as "the king of the learned, the phœnix of the age, and the crown of the virtuous." He died in 1286, in the 60th year of his age.

ABULGHAZI, BAYATUR, a prince of the Tartars, descended from the famous Jenghiskhan, was born in the year 1605; and having passed through a long train of disasters and misfortunes, he mounted the throne of Karuzm in 1645. During a reign of twenty years, by the courage and vigour of his administration, he made himself respected and feared by his enemies. This prince is one of the few recorded in history, who have laid aside the pomp of power, to descend into the peaceful quiet of retired life. In 1665, he resigned his sceptre into the hands of his son, and devoted the remainder of his days to literary pursuits. In his retirement he commenced a work, the genealogical history of the Turks; but his labours were interrupted by death, and the work was completed by his son and successor. It is written in the Turkish language; and being esteemed an authentic history of the Turks and Tartars, has obtained some degree of celebrity. It has been translated into many of the European languages.

ABUNDANT NUMBER, in *Arithmetic*, is a number the sum of whose aliquot parts exceeds the number itself. Thus 12 is an abundant number, because its aliquot parts or divisors, 1, 2, 3, 4, and 6, added together, are equal to 16. It is opposed to a *deficient* number, the aliquot parts of which, taken together, are less, as 14, whose divisors or aliquot parts are, 1, 2, and 7, which added together make 10; and also to a *perfect* number, to which its aliquot parts are equal, as 6, whose aliquot parts, 1, 2, and 3, added together, are equal to the number itself.

ABYDOS, an ancient town, built by the Milesians, on the Asiatic side of the Hellespont, or Strait of the Dardanelles. This place is frequently referred to by classical writers; it is noted in history as the scene of the story of Leander and Hero; and near it was the famous bridge built by Xerxes. As Abydos commanded the passage of the straits, its possession was deemed of great importance to those who were anxious to interrupt the communication between the Archipelago and the Euxine, or Black sea. The desperate resistance which the inhabitants of Abydos opposed to the attack of Philip, king of Macedon, is almost unequalled, in ancient or modern times. When it appeared that the city must fall into the hands of the enemy, the inhabitants vowed, in the most solemn manner, that they would put their women and children to the sword, and destroy all their property, rather than submit to a foreign yoke; and when the Macedonians entered the town, the citizens had actually begun to destroy each other. The work of death was only interrupted by the interference of the victorious enemy. This event took place about 200 years before the Christian era.

ABYDOS, an ancient town of Egypt, situated between Ptolemais and Diospolis Parva, and celebrated for the palace of Memnon, and the splendid temple of Osiris. This city, which was one of the most magnificent in antiquity, was reduced to a village in the time of Augustus, and now presents a heap of ruins. Not far from the ruins is the famous tomb of Osymandes, an edifice of extraordinary magnificence, which had a portico 60 feet high, supported by a double row of massy columns. This forms the entrance to a temple 300 feet long, and 145 feet wide, the roof of which is supported by 28 columns, 60 feet high, 19 feet in circumference at the base, and 12 feet distant from each other. The walls of these spacious apartments are covered with hieroglyphics, among which appear numerous animals, birds, human figures, and some Indian divinities. This remarkable edifice contains many subterraneous apartments; but the passages have been filled up with heaps of earth and rubbish by the Arabs, in searching for treasure.

ABYLA, the ancient name of one of the pillars of Hercules, on the African side of the Straits of Gibraltar, and opposite to Calpe, the other pillar, which is situated on the Spanish side.

ABYSS, in its general acceptation, denotes something which is profound; or, from the literal signification of the word in the Greek, from which it is derived, *bottomless*. In Scripture, this word is applied to the water which God created at the beginning, with the earth, and has been translated by the word *deep*. In the New Testament, the same word, which is translated *bottomless pit*, is supposed to denote hell, and to correspond with the *Tartarus* and *Erebus* of the ancients.

ABYSS is also a term used to denote an immense cavern in the earth, in which God is supposed to have collected the waters on the third day, which, in the English version of the Bible, is translated *seas* and *great deep*. According to some of the older geological writers, this collection of waters still exists in the central parts of the earth, and has a communication with the ocean. This opinion has been opposed by others, and has been the subject of a good deal of controversial discussion. See Woodward's *Natural History of the Earth;* and Cockburn's *Inquiry into the Truth and Certainty of the Mosaic Deluge.*

ABYSSINIA, a large country in eastern Africa, bounded by the Red sea on the east, part of the kingdom of Sennaar on the north, another part of the same kingdom and Kordofan on the west, and on the south by several deserts and mountainous districts, which separate it from Alaba, Gingiro, and Adel. It lies between the 7° and 17° N. Lat. and between the 33° and 43° E. Long. from Greenwich; being about 700 British miles long, and 500 broad. The inhabitants, who are dark-coloured, but without any of the negro features, have long professed the Christian religion, though on all sides surrounded by the followers of Mahomet, and by tribes not yet emerged from paganism. To this country various other names have been applied in different periods; but the term Abyssinia has nearly altogether supplanted them; and, accordingly, those of Upper or Higher Ethiopia, Abassia, Al-Habash, Cephenia, Etheria, &c. are rarely used in modern times.

Face of the Country.—The face of the country is mountainous; to which, in a great degree, must be ascribed a moderate, and, comparatively speaking, healthy climate. Another advantage arising from this inequality of surface is the number of rivers, streams, and lakes, which essentially contribute to the fertility of the soil. These, however, are not so extensively distributed as to supply the demands of the whole of Abyssinia; but, on the whole, few countries of similar geographical situation, are less frequently visited by excessive drought. One of the ranges of mountains which traverse this region, named Taranta, is on the east of the kingdom, extending in a direction nearly parallel to the Red sea. Another occupies the centre; and, besides a third range, towards the southern boundary, there are numerous detached groupes of less elevation in the intermediate plains. These add to the picturesque aspect of the country, and are well fitted for defence. The central range is known by the name of Lamalmon; that on the south, by Ganza. The former contains the mountains of Amhara, and Semena, which, according to one author, are the most elevated in the kingdom. The latter, from the circumstance of its exhibiting a semi-circular form, was imagined by Mr Bruce to constitute part of what have been long denominated the Mountains of the Moon,—an absurd appellation, given to an immense chain, supposed, on very inadequate proof, to run across the African continent. The conformation of the mountains, in general, is imperfectly known; few persons, if any indeed, competently acquainted with mineralogy, having examined them. From their magnitude, however, their mode of arangement, the appearance of their summits, and the circumstance of granite being frequently found to constitute a part of them, there is every reason to conclude that they belong to the class of primitive rocks.

Rivers, &c.—The principal rivers are, the Bahr-el-Az-rek, Abay, Abawi, Astapus, or Blue river, as it has been variously named, and which, for reasons it is unnecessary to state here, was imagined by Mr Bruce to be the Egyptian Nile, whose origin it was the chief object of his celebrated travels to ascertain; the Tacuz, or Tacazze, known to the ancients by the name of Astaboras; the Bahr-el-Abiad, or White river, conceived to be the chief branch of the Nile; the Maleg, said by some to join the Tacazze, and by others to augment the waters of the Abawi; the Mareb, remarkable for its depth and smoothness; the Jemma, a rapid river, equal in size to the Bahr-el-Abiad; and the Hawash, and Hanzo or Hanazo, two smaller but still very considerable rivers, which run toward the Red sea, or rather the Indian ocean, not very far below the straits of Babelmandel. Of the lakes may be mentioned, the Dembea, or Tzana, of variable size according to the season of the year, but at times estimated at 60 miles long, and 30 broad; the Zawaja, one of the sources of the river Hawash, in the south of the kingdom; and Haik, which, though of smaller extent, is of sufficient magnitude to merit distinction.

Climate, &c.—The climate of Abyssinia, it will readily be supposed, from what has been already said, is much modified by the peculiarities of its surface. It is cold and somewhat unkind in the highest region; agreeable and salutary on less elevated lands; whilst in the low plains and confined vallies, much inconvenience, and no small injury, are often experienced from the prevalence of moisture or excessive heat. The range of the thermometer is between 60° and 80°, rarely exceeding in either direction, and more rarely towards cold. The appearance of ice and snow, therefore, is utterly unknown in the inhabited parts of the country; but the popular legends make mention of the supposed miraculous occurrence of white rain, and a hard transparent substance on the surface of the water, on some very particular occasions; and this description is abundantly verified, for European faith at least, by the testimony of Mr Pearce, who was long enough in Abyssinia to have an opportunity of witnessing the occasional existence of both on the top of the loftiest mountains. The seasons are not uniform, but appear to vary in their duration and periods of approach, according to the situation with respect to the mountains. This accounts for the discordance in the relations of those authors who have treated of the subject. Perhaps, also, it is proper to admit, that, as in other countries, certain disturbing causes occasionally produce variations in the commonly observed uniformity. But, on the whole, we may conclude, that there is no great difference between the seasons of Abyssinia, Egypt, Barbary, and the Syrian states.

The soil, which must be various, cannot be reckoned ungenerous; for, if the industry and skill of the people were equal to its capability, it would yield every necessary, and many of the luxuries of life, in the greatest abundance. Neglected, or mismanaged as it is on their part, nature has done her's, in no illiberal manner, singularly favouring some districts, especially those which are watered by rivers, with most luxuriant and often renewed vegetation. Wheat, barley, teff, and other grains, are amongst the alimentary products; and of these there are sometimes even three harvests in the year. The first is usually about the end of November, the second in the end of February, and not unfrequently a third succeeds towards the end of March, immediately previous to one of the rainy seasons. Besides the articles now mentioned, different districts yield cotton, linen, wax, and honey, various aromatics, abundance of fruits of the richest kinds, and many other productions, the excess of which beyond the demands of the natives answers the purpose of trade with foreign countries.

Divisions.—Abyssinia has been variously divided at different periods; but its political divisions are so liable to changes, from causes to be afterwards specified, that even the enumeration of its several provinces, as given by Mr Bruce, who visited the country in 1769, is unsuitable to its present condition. That which we are about to detail is on the authority of the more recent information of Mr Salt, who divides Abyssinia into three independent states, viz. Tigré, Amhara, and the united provinces of Shoa and Efat.

Tigré and Amhara are distinctly separated by natural boundaries, viz. the high range of mountains in Samen, which extend from Waldubha to the south of Lasta, and the course of the river Tacazze along the base of that range. The character and language of their respective inhabitants form, besides, a striking cause of distinction, which it is exceedingly improbable that political circumstances should at any time altogether subvert.

Tigré, at present the most powerful state in Abyssinia, is bounded on the north by the Bekla, Boja, Takue, and Shangalla tribes; on the west and south-west, by the mountains of Samen; and on the east, south-east, and south, by the Gala, Doba, and Danakil tribes. It comprehends about 4° in Lat. and as much in Long., and is divided into several provinces. The central province is Tigré proper, from which the denomination of the whole is derived; and it is bounded on the north by the Marat, on the east by Agami, by Shiré on the west, and the river Warre on the south. In general it consists of ranges of hill-forts, intersected by deep gullies and well cultivated plains. Agamé, to the east of Tigré proper, is a rich and level country, considerably elevated above the sea. Its eastern frontier, which is the high ridge of mountains extending from Senofé to Taranta, its strong holds on the Taltal, and its vicinity to the Salt-plain, which is an object of so much consequence to Abyssinia, contribute greatly to the importance of this province. On the south of Agamé are the mountainous districts of Derra, Asme, Womburta, Desa, Muntilla, and Monos, forming part of the province of Enderta, which comprises also the territories of Moculla, Dirbah, Gambela, Upper and Lower Gibba, Wazza, Saharti, and Giralta. Antalow, the capital of Enderta, is well situate for defence against the attacks of the Galla, from which Abyssinia has so often suffered of late years: it has accordingly been chosen for the residence of the Ras or sovereign of the province, though Chelicut in its neighbourhood, which may be considered as a country seat, be his favourite place of abode. A long and narrow region, running in a direction from east to west, called Wojjerat, lies to the south of Enderta. It is said to be covered with forests, to abound in beasts of prey, and all kinds of game, and is much celebrated for its white honey. The small low district of Wofila, where the adventurous Galla have succeeded in intermixing with the native Abyssinians, is to the south of Wojjerat. In the same direction lies the almost inaccessible province of Lasta, noted for its mountains and soldiery; and to the north lie the two provinces of Bora and Salowa, which much resemble it in hilly aspect. Still farther to the north is Avergale, a narrow flat country, extending 50 miles along the eastern side of the Tacazze. On the western side of this river is the province of Samen, whose mountains are reckoned to stretch about 80 miles from north to south. Between the most northerly part of this extensive range and Tigré proper, is Temben, a valuable province, divided into several districts, each of which has its separate chief, or Shum, as he is called. It has been noticed, that the houses in this province, and in Avergale, resemble the ancient Egyptian temples, and are usually built without mortar. North of Temben is the province of Shiré, forming a sharp angle with the Tacazze, by which it is separated on its western side from the beautiful and fertile districts of Waldubha and Walkyt. The north-east province of Tigré is commonly called the kingdom of the Baharnegash, and comprises a great many districts, all of which are ruled by different chiefs.

Amhara, the second division of the kingdom, is no longer subject to it, having been subdued by the Galla, between whom and the people of Tigré there exists a state of perpetual hostility. Since their conquest of Amhara, the Galla have in great measure adopted the more civilized manners, the dress, and mode of living of the Abyssinians. The name of Amhara is still retained, probably on account of the language prevailing there. It comprehends the provinces of Begemder, Menna, Belessen, Foggora, Dembea, Tcherkin, Knara, Tchelga, Maitsha, Gojam, and Damot. Some of these are extremely rich, and at one time, indeed, constituted the most important part of the kingdom. Thus, Gondar, the capital, is situate in Dembea, one of these provinces; but the king, who still resides there, is almost entirely neglected, having but a few attendants, and keeping up a mere resemblance of the ancient dignity of his office.

Of the united provinces of Shoa and Efat, which form the third, or southern division of Abyssinia, and which are now entirely separated from the others by the Galla, the former is described as a high track of land, running north and south, and throwing off a number of small streams; and the latter, which is on a lower level, is celebrated for its fine pasturage and fertile vallies. It is said also to contain many large towns, and an immense number of monasteries. From all the accounts which Mr Salt received, he was inclined to think that Ethiopian literature might be found in a more flourishing condition here than in any other part of Abyssinia, and that the inhabitants retain more of the ancient customs and peculiar manners of their forefathers than either of the other two states.

The natural history of Abyssinia presents an interesting variety of objects.

Quadrupeds.—All the common domesticated quadrupeds are found in abundance. The Galla oxen, or Sanga, are remarkable for the size of their horns, some of them amounting to four feet in length, and to upwards of twenty inches in circumference at the base. Mr Bruce conjectured, that this peculiarity was the effect of disease, and that great pains were taken to encourage it. But in this he was entirely mistaken, as the observations of Mr Salt have shewn. Several specimens seen by him were in perfect health, three of them indeed so exceedingly wild that it became necessary to shoot them. The horns of one have been deposited in the Museum of the College of Surgeons in London, and a still larger pair adorns the collection of curiosities belonging to Lord Valentia at Arley Hall. The animal is not of greater size than is common to the genus; its colour is not peculiar; and both male and female are provided with these gigantic ornaments.

Wild animals are extremely numerous. This seems to indicate, either the unimproved state of the country, or the frequency of wildernesses and thick forests. Lions are found in the sandy districts bordering the Tacazze; but as the killing of one of them confers a certain degree of honour, it is probable they are not in great numbers. There are several species of the leopard tribe, some of which are said to be very fierce, and to prove destructive to children, and even men, occasionally carrying them away, if found asleep or unprotected. Hyænas exist in vast numbers, and are exceedingly ferocious. The howling of this animal is very peculiar. It consists of three distinct deep-toned cries, succeeded by a few minutes silence, when they are repeated.

Wolves, foxes, and jackals, as well as several species of lynx, are common; antelopes, and wild goats of various kinds, abound in some districts, with wild boars, porcupines, hares, squirrels, rats, &c. Elephants are met with in all the forests which border on Abyssinia. They are hunted for their teeth, by the Shangalla, a tribe of negroes to the north of Tigré. The wild forests of Wojjerat are frequented by a species of rhinoceros having two horns. These constitute an article of trade in the east, where they are used as handles for swords and daggers. The skins are employed for shields.

The buffalo is common in some parts of Abyssinia. That singular animal, the giraffe, or camelopard, is occasionally seen; but his shyness and timidity confine him to the most unfrequented parts of the country. His skin is an article of barter; and the hair of the tail is converted into an instrument for brushing away flies which are so troublesome in the hot season. The zebra and wild ass are found in the southern provinces. The mane of the former is much sought after for making a sort of collar to adorn the war horses of the chiefs; but its scarcity is probably the reason why only a few of the principal men have the privilege of wearing it. The hippopotamus and crocodile are found in the large rivers. The latter being in great numbers, and often of an enormous size, justly excite the dread of the natives at the thought of bathing, or even going near the water, unless with the utmost precaution to avoid danger from their attacks. Mr Salt had a good opportunity of proving the impenetrability of the hide of the former animal to common musket balls. Several shots were fired at one of them, and appeared to strike him, as was believed, from his angry-like noise and suddenly plunging deep into the water. Shortly afterwards, however, he rose again, without seeming to be hurt; and though another charge was made on him, there was no reason to think that he received any material injury.

Birds.—Abyssinia is plentifully supplied with birds, and their variety is very considerable. Mr Bruce has given a description of two belonging to the falcon genus; one of these he denominated the Golden eagle, by way of distinction. Dr Shaw ranks it among the vultures, terming it the "Bearded vulture." Mr Salt again, from its general appearance, and the great vigour and animation which it displays, inclines to class it with the eagles, calling it the African bearded eagle. Of one shot by him, the extent betwixt the tips of the wings exceeded eight feet. In addition to the second species named by Dr Shaw, the Occipital eagle, and which is rare in the country, there is a third, not before noticed, which Mr Salt proposes to designate by the name of the "Abyssinian white-breasted Lanner," the whole of its breast being of a clear white colour. It is about the size of a common falcon; its feet and beak are of a blueish tint, and its general colour is a deep brown, verging to black. This bird is held in high veneration by the natives, who will on no account suffer it to be killed. From several superstitious notions concerning it, and its resemblance in form to a figure he frequently met with in the hieroglyphics in Egypt, Mr Salt conceives it to be a species of the hawk, venerated by the ancient inhabitants of that country. Immense flocks of vultures are to be seen in Abyssinia, especially in the rear of an army, which, either by instinct or experience, they appear to expect will supply them with provisions; in this, generally, they are not disappointed. By the beneficent order of nature, these ravenous creatures feast on the remains of the slaughtered cattle, and the bodies of the slain and diseased soldiers, which would speedily, in such a climate, render the atmosphere destructive to animal life. At other times, and in other places, they feed on shell-fish, the wild beasts which have fallen by the hands of the hunter, or such smaller animals as their own strength or ferocity, stimulated by hunger, can overcome. The ostrich is somewhat rare. Herons are common, as well as numerous species of water-fowl; and the whole country is said to abound with red-legged partridges, quails, snipes, lapwings, &c. &c. Only one species of parroquet has hitherto been discovered. Pigeons, larks, and thrushes, are abundant.

We may now notice some of the less known, or, till Mr Salt's time, non-descript birds. *Bucco Saltii*, a new species so named by Lord Stanley, who has contributed notes to Mr Salt's appendix, in honour of that traveller as its European discoverer. This bird bears some affinity to the doubtful barbet of Latham, but may be distinguished from it. The length is about seven inches. Its bill is of a blackish horn colour, rather more than an inch in length from the gape to the tip, and about three quarters of an inch thick at the base, with two notches in the edge of the upper mandible, and a sort of indentation in the lower, but without any channel on the bill as in Latham's bird. The general colour of the plumage on the body is black; but the whole of the face, from the crown, round by the eyes and the ears, as far as the breast, is bright red; the wings are dusky; except the primaries, the quills are margined with yellowish green; and the legs and claws are dark. This bird, like the common woodpecker, clings to the branches of trees. The *Certhia Tacazze*, or splendid creeper, is one of the most beautiful birds of the kind. The head, neck, breast, upper part of the belly, the back and rump, the upper coverts and bend of the wing, exhibit a metallic lustre of the greatest brilliancy, partly green, partly purple; whilst the wings, which are dusky, have an edge of deep blue, and the lower part of the belly, the legs, and claws are black. The tail is of a bluish-black colour, but with large edges of a bright steel blue, and would be round in shape, did not the two middle feathers exceed the rest in length, nearly two inches. This bird is eight inches and three quarters in length; and its bill, which is much bent, and of a black colour, is an inch long. The *Tanagra erythroryncha*, or red-billed tanager, is the name given by Lord Stanley to a bird, of which Mr Salt saw vast numbers, especially wherever there were droves of cattle. It resembles the African beef-eater, in size, the arrangement of the feet, and the general colour of the plumage. The peculiarity in the habit of this bird is his feeding on the backs of cattle, whence he picks out a species of grub, engendered there during the hot weather, and which, without his friendly appetite, would prove extremely distressing. The *Merops furcatus*, or fork-tailed bee-eater, is above nine inches in length; has a black bill, about an inch and a half long; is, in general, of a bright yellow-green colour, but in some lights shews a golden, and, in others, a chesnut tinge; the chin and throat are bright yellow, edged with a line of bluish-green, and below the latter there is a straight bar of ultra-marine blue; the under parts of the body, and the tail coverts, are of a bluish-green. The tail, as the name implies, is forked, and the legs are weak, and dusky, with a reddish tinge. A list of more than 60 rare birds, in Mr Salt's publication, testifies the richness and variety of this department of Abyssinian natural history.

Insects.—Of the insects found in this country, those most requiring notice are, a species of fly called *tsaltsalva*, or tlatsalva, and the locust. The former, though little larger than a bee, is extremely formidable. Fortunately he is rarely encountered, and is principally confined to places where there is a black loamy soil. The wound he inflicts is extremely difficult to heal, and often gives rise to inflammation and gangrene, ending in the death of the sufferer. Mr Salt has completely confirmed the previous reports concerning the destructive powers of the locust. During his stay in an island on the coast of the Red sea, a flight of these insects, in a few days, destroyed nearly half of its vegetation; and he had convincing evidence, that it was no unusual thing for them to lay waste very extensive tracts of land. In addition to what Drs Russel and Shaw, and other writers, have said, as to these creatures being sometimes eaten in different countries, this gentleman informs us, that the wandering tribes of Yeman and Dankali commonly use them as food,—first of all broiling them, then separating their heads from their bodies, and devouring the latter, in the same manner as Europeans eat shrimps and prawns. This is certainly a suitable retaliation. But it is surpassed by what they experience from bustards, lapwings, and other birds, which contrive, in a summary way, to swallow them without any culinary or decapitating operation.

Fishes, &c.—We have no satisfactory account of the fishes found in this country; and, according to Mr Bruce, there are not many serpents, as had often been reported before his time. Of the individuals of the latter class, we may mention the *boa* snake, which is sometimes found in the low country of Abyssinia, and a species of horned viper, called *cerastes;* but the descriptions of them, and of the mode of incantation, as it is called, which has been practised on the latter, will be noticed in our natural history of those animals.

Plants.—The geographical situation of Abyssinia, its many local advantages, and the differences of soil and climate which it presents, secure to it the greatest beauty, and most abundant variety of vegetation. Indeed, nearly every plant, which requires either a very low, or a very elevated situation, great warmth and moisture, or a cold and arid soil, may be expected to adorn it. Fruits, flowers, and aromatics, are produced in the greatest perfection; and to these must be added a number of plants, which ingenuity has made subservient to the necessities and comforts of our species, or experience has ascertained to prove serviceable in alleviating or removing disease. But we could not presume to enter upon a specification of individuals; for Mr Salt, in his list of new and rare plants, collected during his stay here, enumerates more than a hundred species above what Mr Bruce had observed.

Both Mr Bruce and Mr Salt, who seem to have possessed a taste for natural scenery, were struck with the general luxuriance and beauty of this country. They have, accordingly, written under the evident impulse of an excited fancy, so as to produce no small degree of interest and pleasure in the reader. Perhaps, then, we could not do greater justice to this part of our subject, or, indeed, to the account of Abyssinia in general, than by giving a view of the most striking objects that were presented to them. Mr Bruce's work, however, has been so long before the world, and is so universally read, as to render any such labour, with respect to it, unnecessary. A few notices, therefore, are all we shall derive from it; but of Mr Salt's more recent publication, we shall avail ourselves in an ampler manner. The following abstract will serve also to introduce, and connect together, all the accounts which it is necessary to detail respecting the manners and customs of the people.

Bruce's Journey.—Mr Bruce left Arkeeko, a town near Masuah, or Massowa, on the 15th of November 1769, intending to proceed to Gondar, the capital of Abyssinia. Having changed his course from south to west on the 17th, he arrived, on the same day, at a range of mountains, over which he could find no other passage than what had been produced by torrents of water, which often, in this climate, come on with such rapidity and force as to prove highly alarming, if not dangerous to the traveller. Till the 20th, his journey was either along one of these, or on the banks of a small river, well shaded by sycamore trees, some of which were above seven feet in diameter. On that day, he reached the mountain of Taranta, which presented still greater difficulties than he had yet experienced. The ruggedness of the path, the frequent occurrence of immense gaps or fissures, occasioned by the excessive rains, and the obstructions produced by large fragments of rocks which had tumbled down from their original connexions, would have been sufficient to deter any less spirited adventurer. The eye was often delighted, however, in the appearance of trees, especially on the lower and middle regions; they were chiefly the Kolqual, olive, and cedar, which, in any situation, would afford a pleasing effect: And, on the top, a village of shepherds, flocks of sheep, and cattle of various kinds, some of them of a very beautiful white colour, besides a plain, on which wheat had been sown, administered the comfortable thought, that, even here, the liberal hand of nature had distributed the marks of her indulgence and providential care.

The western descent was equally rugged and difficult; but, on approaching the town of Dixan, the road considerably improved. Dixan, which is the first town in Abyssinia on the side Mr Bruce entered, is situate on the top of a hill of a conical shape, surrounded by a deep valley, and having no other access than by a path which winds round. Between Dixan and Adowa, lay a fertile and tolerably well cultivated country, producing several kinds of grain, and a variety of trees and flowers. Adowa, once the capital of Tigré, did not contain above 300 houses, but it occupied a large space, as the houses were generally encircled with plantations of the wanzey tree. It is on the declivity of a hill, and is watered by three rivulets. The houses are of stone, cemented with mud, the use of lime being almost confined to Gondar. The town of Axum, in its neighbourhood, once the capital of the empire, justly merited his next attention, on account of its former grandeur, and of the ruins, which are still contemplated with veneration. Siré, the next town he visited, is larger than Axum, and is said to contain about 600 houses. The intervening country has a very fine appearance; and a considerable part of the road lay over the remains of a magnificent causeway. Siré was noted for a cotton-cloth manufactory. On leaving this place, he traversed an extensive plain, covered with grass, and occasionally presenting a few detached hills. He soon afterwards crossed the river Tacazze, and then arrived at the mountains of Samen. Of the difficulties of passing these remarkable heights, it may be allowed that he has given a faithful report; but, in his description of the hills themselves, especially as to their forms, he has made, perhaps, rather unfair demands on the credulity of his reader. It required, indeed, great confidence in that principle, to assert, that some of these hills are like pyramids, pitched on their points, with their bases uppermost! Mr Salt assures us, he did not see a single instance which corresponded with such a description; and most readers, it is presumed, even allowing a good deal to fancy, would incline to deny the existence of such anomalies without the aid of his authority. Mr Bruce, with great perseverance, and much toil, reached the top of Lamalmon mountain, on the north-west part of the high land of Samen, of which he has given an interesting account. It is surmounted by a large plain, from which issue several springs, the sources of the principal rivers in this portion of Abyssinia. On approaching Gondar, the country improved in cultivation. His account of this capital, and of the various events in which his residence in Abyssinia engaged him, will afford much entertainment to the reader.

Salt's Journey.—Mr Salt, in both his journies in this country, set out, as Mr Bruce had done, from Arkeeko, in the direction of Dixan.

Arkeeko is an assemblage of miserable huts, inhabited by a set of rogues and half-civilized savages, who have contrived, whilst losing the rude virtues of their original state, to imbibe the worst vices of people more advanced than themselves. It is scantily supplied with fresh water from six wells, about a mile and a half distant; where it is usual for men, women, and children, to assemble in the evening, for the purpose of collecting and carrying it in skins, as is common throughout eastern countries. Passing these wells, to which the name of Illerbehey is given, Mr Salt reached a rising ground called Shillokeab by Mr Bruce. The road onwards to Weah, which is a small stream or torrent, lay over a rugged ridge of low hills, the basis of which consisted chiefly of granite, rising above a bed of micaceous earth; and the face of the country was nearly covered with the thorny Acacia, whose sun-burnt leaves afforded little repose to the wearied eye. A short distance from Weah, which is conjectured to be about 18 miles from Arkeeko, there is a forest of girá trees; and a little beyond this, the mountains commence, along whose ravines and declivities there is a winding road, which continues as far as Taranta. Some encampments of the Hazorta, a wandering tribe, and a village or two, were passed on the way. In both his journeys, Mr Salt found the thermometer to stand above 80°, near the same situation, in the months of February and July. The hills now met with, are generally described as composed of burnt brown stone, with a few layers of white spar; and, at one point, we are told, a rock was found, which contained so much iron as to affect the compass. Some springs and natural cisterns were occasionally seen. Torrents were frequently encountered; and both Mr Bruce and Mr Salt, it may be remarked, experienced a dreadful storm, nearly at the same place. A few very pleasant spots, called Sadoon, Tubbo, &c., partly described by Mr Bruce, yielded the refreshments of water, some fruits, game, and, above all, the enjoyment of beautiful scenery. The Hazorta, Welleihah, Bedowee, and many other tribes, had taken up their abode at various points of this course; some of whom were, perhaps, nearly as much to be dreaded as any of the wild beasts which occasionally roared around them. It was found practicable, however, to get through both, without any very material inconvenience; and, at last, the pass of Taranta was reached, which Mr Bruce had described in so terrifying a manner. Immense difficulties, of course, were anticipated by Mr Salt in his first visit to this noted region; but his experiencing how easily he could overcome them in three hour's time, including several delays, so far moderated his apprehensions on his second journey, that he found leisure to amuse himself with the many beauties and rarities which presented themselves.

The view that bursts upon the traveller when he attains the height of Taranta, is said to be one of the most magnificent that imagination can delineate; "extending over the abrupt mountains of Tigré, to the pinnacled and remote heights of Adowa, and singularly diversified with patches of vegetation, extensive forests of Kolqual and numberless intersecting vallies." The thermometer, on the summit, varied from 59° to 66° in the month of July.

A remarkable change of climate was experienced on reaching the wild and rocky district that stretches from the foot of the mountain towards Dixan. The sun was hot and scorching; vegetation had a parched appearance; the brooks were dry; and the cattle had been driven off in search of pasture. Many of the rocky mountains, in the country round Dixan, are planted with villages constructed much in the same manner, only with flat-roofed houses, having neither windows nor chimneys. The place of the latter is badly supplied by two pots of earthen ware, rising out of the roof. A chapel, the only public building in Dixan, is held in great veneration by the priests and people in general, who have a great fondness for crosses, and a strong propensity to kiss whatever they hold sacred. But their religion, unfortunately, seemed to have no efficacy in reclaiming them from the vices of idleness, ignorance, and dirt—a defect, too serious in its consequences to be compensated by the foolish habit of uttering some jargon, profanely denominated prayers, on the most trifling occasions.

Marriages, &c.—Here we may mention several peculiarities, noticed as general with this people. Circumcision is practised. Boys marry at fourteen years of age, and girls sometimes so early as ten. The laborious occupations devolve, as is not unusual in half-civilized countries, on the female sex. Polygamy is allowed; but there is always one wife to whom the law allows a superiority in point of consequence, however the affections of the husband be elsewhere disposed of. Marriage itself is generally held to be a merely civil institution, the priests rarely officiating at the ceremony. There is indeed a holier kind, at which they assist, when the parties take the communion, and this is reckoned to be indissoluble—a very sufficient reason why, in a country where licentiousness is on the increase, the common mode of coming together, which allows of very easy separation, is now universally preferred. It is curious, that the wife always preserves her own name. She is entitled also, which is a still better institution, to recover the whole of her dower, in the event of the husband's misbehaviour occasioning her to quit his home: but it is lost on her own infidelity being proved—an event, perhaps, not of very easy discovery, as the law requires her to be caught in the act. Another peculiarity, of no small interest, has often been aimed at by the fair sex in other regions; the ladies of rank are accustomed to assume a high degree of superiority over their husbands!

South from Dixan lies the plain of Zarai, which, Mr Salt says, reminded him of the vale of Evesham in Worcestershire. It was highly cultivated, and disposed in ridges, for the convenience of irrigating the land; a practice not unusual in this country. Still further south, beyond the village of Ascariah, and a pretty steep declivity, there is another fine plain, called Serawé, which forms a part of the western boundary of the mountains of Taranta, which have a remarkably wild appearance from this position. Onwards is the picturesque village of Abha; and there are several other villages scattered throughout this part of the country. The church at Abha is partly excavated out of a rock, rather difficult of access, and apparently not so often visited as that at Dixan. A weekly market, held in the immediate vicinity, attracted much more notice; man's physical wants, here, as elsewhere, commonly obtaining most of his regard. Not less than three hundred persons had assembled to barter their various goods, such as horses, cattle, skins, butter, iron wrought and unwrought, &c. &c. much in the same manner, and no doubt with equal avidity, as in any English village; and nearly as many more were met with on the road, in straggling parties, conveying their merchandize; a pretty good test of the population and prosperity of the place.

In his first journey from Abha to Antalow and Chelicut, Mr Salt went by the east of the Devra Damo, and Haramat mountains; and in his second, he took the western side of this ridge. The former route lay through a number of villages, most of which are small and inconsiderable. The country, in this direction, exhibited very various appearances; as insulated rocks, difficult mountain passes, hills of remarkable forms, extensive flats, cultivated vallies, rich pasturage, many plants of great beauty, vast herds of cattle, and flocks of sheep. On the whole, making allowance for peculiarities in manner and habit, a good deal of hospitality was experienced; and, in general, maize, the intoxicating beverage commonly drunk in Abyssinia, and which is prepared from honey, fermented with barley, and strengthened by a bitter root called taddo, was supplied in very liberal doses. This is the liquor which Mr Bruce calls hydromel. The other course conducted Mr Salt to Logo, a large town near the river Seremai; the village of Legote, which bore a resemblance to Dixan; a remarkable pass, called Kella, a word signifying, in the Abyssinian and Arabic languages, "a castle," and given to it on account of the shape of the rocks in its neighbourhood; a very rugged mountainous dictrict, where the path was so steep as to require the travellers to dismount from their mules; a very extensive plain, stretching from the hills of Agame and Haramat, in a westerly direction towards the river Tacazze; another pass, leading to the district of Giralta; and the towns of Mugga, Gibba, and Moculla, situate in the rich and fertile plain of Gambela. Of the information collected in these two tracks may be mentioned a few particulars, illustrative of Abyssinian manners, &c. The bad contrivance of the houses with respect to chimneys, exposes the people so much to smoke, that even many of the children were nearly blinded by it, and almost every woman advanced in years had lost either one or both eyes. On the death of near friends, the Abyssinians go into deep mourning, both men and women clothing themselves literally in sackcloth and ashes. They shew also their affection for the dead, by tearing the skin off their temples; a practice something similar to what prevailed amongst certain ancient people, and is now found in some of the South-Sea islands, viz. cutting and maiming the body as a token of grief. Lent is observed by the higher classes with very particular attention.

The unfortunate dissensions which existed during both his visits to this country, prevented Mr Salt from going to Gondar. But the friendly disposition of the Ras Wallad Sélassé enabled him to traverse Tigré in any direction he chose, and contributed materially to his opportunities of acquiring information on every subject he deemed worthy of his regard.

Eating Raw Flesh.—One of the most extraordinary relations contained in Mr Bruce's account of this country, and which, perhaps, more than any thing else exposed him to censure, was that of a practice which he attributed to the people, of cutting portions of flesh from the bodies of living cattle, and serving them up quite warm, and without preparation, to the table. The barbarity of this action was thought so extreme, that perhaps any man's veracity would have been questioned who should have asserted its reality. There required nothing more, then, in addition to certain other very debateable points, to bring on him the charge of falsehood. Mr Salt seems to have gone into this common accusation, during his first journey. His observations did not prove the alleged enormity, though they were ample enough to ascertain a very considerable approach to it, in the common practice of eating slices of flesh, called *brinde*, taken hot and quivering from the slaughtered animal. His own account of a feast of this sort, therefore, is abundantly horrible and disgusting. To be sure, the life, at least the sentient principle, was not present, to give the exact amount of Bruce's previous statement; but a little candour might have suggested the possibility of complete coincidence, in certain situations, different from those in which he himself happened to be placed. Accordingly, in the narrative of his second journey, he is actually induced to make mention of scenes of barbarity, which, to use his own words, "appear strongly to corroborate the account given by Mr Bruce!" The statement is made by Mr Pearce, one of his establishment, and is too curious to be omitted. "Mr Pearce went out with a party of Lasta soldiers, on one of their marauding expeditions; and in the course of the day they got possession of several head of cattle, with which, towards evening, they made the best of their way back to the camp. They had then fasted for many hours, and still a considerable distance remained for them to travel. Under these circumstances, a soldier attached to the party proposed "cutting out the shulada" from one of the cows they were driving before them, to satisfy the cravings of their hunger. This term Mr Pearce did not at first understand; but he was not long left in doubt upon the subject; for the others having assented, they laid hold of the animal by the horns, threw it down, and proceeded, without further ceremony, to the operation. This consisted in cutting out two pieces of flesh from the buttock, near the tail, which together, Mr Pearce supposed, might weigh about a pound; the piece so cut out being called "shulada," and composing, as far as I could ascertain, part of the two "glutei maximi," or larger muscles of the thigh. As soon as they had taken these away, they sewed up the wounds, plastered them over with cow-dung, and drove the animal forwards, while they divided among the party the still reeking steaks. The animal, after this barbarous operation, walked somewhat lame, but nevertheless managed to reach the camp without any apparent injury; and immediately after their arrival it was killed by the Worari, and consumed for their supper!" Mr Salt immediately afterwards remarks, that the fact of this practice being occasionally adopted was certainly placed beyond all doubt, by the testimony of many persons, who declared that they had likewise witnessed it, particularly among the Lasta troops.

Feasts, Amusements, &c.—*Brinde*, though a favourite dish, is by no means the only one that constitutes an Abyssinian entertainment. There is considerable variety of fare in the houses of persons of rank. Cowheel, grilled mutton, curried fowl, fish of different kinds, with an abundance of fruit, yield sufficient enticements to the indulgence of appetite. The people, especially those of rank, when entertaining, shew a good example in doing justice to the feast, eating and drinking enormously; and it seems to be considered as essential to kindness, that they should press their guests to do the same. Solicitation to this effect, however, is not here as in some other countries the only means adopted to overcome the reluctance, or satiated feelings of their friends. On the contrary, the host would be thought very deficient in politeness and hospitality, if he did not actually put his victuals into their mouths, much in the same manner, we learn from Mr Salt, as boys feed young magpies. A very modest man, therefore, in such liberal hands, would stand no small chance of being crammed to death. Marriages, births, and all other convenient occurrences are taken advantage of, to administer festivity to this active and lively people. Their rejoicing is pretty much alike on all such occasions, and is always accompanied by most circumspect regard to the substantials of life. Their mirth, however, which almost invariably degenerates, or improves, as they no doubt think it, into intoxication, is productive, at least amongst the higher ranks, of very few quarrels; and Mr Salt says, he never knew an instance of any one drawing his knife on such an occasion. In their private parties, a great degree of freedom is enjoyed, and the sexes are by no means restrained in their very natural desire to associate. Their conversation does not seem to be the most refined, or altogether very delicate, even in presence of the ladies, who do not scruple to *hear* things with a good grace, and some apparent satisfaction, which elsewhere would be so totally unintelligible to them, as not to produce a single emotion. The young women, however, are said to be well educated; and no doubt the early marriages of the country are very beneficial, as the husbands in general are fully disposed to watch the preservation of their morals. Children are treated with severity, and those who are illegitimate do not inherit the father's property, but are considered nearly in the light of servants. Land descends from father to son, and if there is no son, to the brother. All the children, however, and the relations, have a claim to a maintenance. The poor and the distressed are, on the whole, charitably assisted, and slaves are well treated. Pilfering and dishonesty are far from being rare; and an eagerness for presents is very universal. The people are fond of amusement. Chess is one of their favourites. The indulgence in comic humour is not unusual among them. They have a sort of rude poetry, in which they delight. Musical instruments of a simple kind are pretty common; and some of their pic-

Abyssinia.

tures are not destitute of ingenuity. Few of their manufactures are important;—those of coarse carpets in Samen and at Gondar, from the wool and hair of sheep and goats,—of knives at Adowa,—and spears and razors at Antalow, may be reckoned the chief. The implements of husbandry in use, are very rude; the plough, for example, is shaped out of the root and branch of a tree, to which, sometimes, a ploughshare of iron is added. It is drawn by two oxen, and guided by men only; but, in all the other departments of husbandry, the women have the larger share of labour. Their greatest toil, perhaps, is that of clearing away weeds, which the luxuriance of the soil frequently renews. Reaping is exclusively committed to females.

In his visit to the antiquities of Axum, Mr Salt had full opportunity to correct several errors into which Mr Bruce had fallen, and also to ascertain some points of interest in the history of Abyssinia. The particulars are too numerous to be noticed here. He was less fortunate, in being prevented, as we have mentioned, from going to Gondar. Any account, therefore, we can give of that capital, must be collected from the previous information of Mr Bruce, and such reports as his repeated inquiries procured him. This, however, is perhaps little to be lamented, as, even admitting the full effect of the opinion which the natives entertained of it, there is not much reason for solicitude as to either the minuteness or the grandeur of the description. The town has neither walls nor fortification. The palace is the principal building. But there are many churches, for the splendour of which, the Portuguese, who formerly had great influence here, must be allowed to claim merit. Gondar is situated on a hill of considerable height, and occupies a large space, as the houses in general are only one story high. It is said to contain about ten thousand families.

Government.—Of the government of Abyssinia, it is extremely difficult, for reasons already mentioned, to give any satisfactory account. In former days it was undoubtedly monarchical, and of the most absolute kind, the will of the sovereign being supreme, and his power irresistible, at least by any thing established in behalf of popular feeling and interest. The throne was hereditary in one family; but the individual who filled it was commonly elected by the ruling minister, who frequently nominated an infant for the successor. The consequences, as might easily be foreseen, were almost perpetual disputes and animosities, amongst the persons of the blood-royal. To prevent mischief from this cause, it was usual to confine the members of the royal family in the mountains of Week-ne or Way-gne, and in other fastnesses, in a state of complete seclusion from the business of the state, and, indeed, the common concerns of life,—a peculiarity in Abyssinian history, of which Dr Johnson has availed himself, in his beautiful fiction of Rasselas. This custom has been abolished for several years, and the princes now usually live in a kind of dependent condition on the chiefs of the different provinces, who may be said to have shared among them the power and consequence of royalty. This being the case, and Abyssinia having, in fact, dwindled into a sort of rival and uncombined aristocracy, it is less necessary to occupy room in any account of the national revenue, the kind and number of state officers, or other peculiarities of constitution and government, which form so essential a part of the history of most nations.

Money, &c.—In place of coin, or even of massive gold and silver, the Abyssinians employ pieces of salt, obtained originally from the salt plain, and cut into different sized pieces, for the medium of trade. Cotton cloths sometimes answer the same purpose. Recently, it seems, foreign coins have been introduced, which, in more favourable circumstances of the country than have long existed, would, probably, from its much greater convenience, give rise to a national currency of the precious metals. Perhaps a small kind of glass beads, which are commonly used in the minor payments, is to be considered as the more important approximation to such an advantage, as indicating the universal acquaintance with the operation of what may be called a representative system of exchange. The Abyssinians have measures of capacity and weight, which, in their various subdivisions and modes of adjustment, indicate a suitable degree of attention to the necessary trading occupations.

History.—The early history of Abyssinia is involved in the greatest obscurity, and seems to present difficulties which it is impossible to solve. To ascertain even the origin of the people who have so long inhabited this country, would lead to discussions of no ordinary compass or perplexity. Till lately, indeed, the opinion of Ludolf, that they were derived from the Arabians, was so commonly received, that it might be assumed, unsupported as it was, and liable to serious objections, without apprehending the smallest opposition, or any unfavourable imputation. It is not the least merit of Mr Salt, that he disputes the evidence on which this opinion was founded,—for it is praise-worthy to arrest the despotism of fictitious authority; but, in addition, he has assigned reasons of at least a very plausible appearance, for the supposition that Egypt, and not Arabia, is the country whence the Abyssinians proceeded. The only strong objection that seems likely to prevent the general adoption of this supposition is, what the late very learned editor of Bruce's Travels, Mr Murray, remarked, as to the similarity between the Geez and Arabian languages. But this is readily enough explained by Mr Salt, on the principle which that gentleman himself maintained, viz. that the Hebrew, being the most ancient language in existence, is the common stock from which they have been derived. This reply, it is obvious, is merely an *argumentum ad hominem*, and may not obtain the assent of those who deny the major proposition. Besides, as it might easily be shewn, the consequences of this proposition, even admitting its truth, are of so general an application, that we must discard it entirely from the investigation, unless we mean merely to prove, what is not disputed in this case, that the Abyssinians and the Arabians are descended from Noah. It would have been better, perhaps, if Mr Salt had chosen a more special ground for the defence of his opinion, and had been at some pains to inquire, or at least to state, what probable events had preserved the resemblance of language, whilst the institutions, modes of building, dress, written characters, and other peculiarities of one of these people differed so materially, as he affirms they did, from those of the other. Now, in this respect, we think he might have been most materially aided by the labours of the industrious Bryant, who perhaps has done more towards the elucidation of this point of history, though merely incidental to the peculiar objects of his research, than any previous or subsequent author. We refer the reader to his Analysis of Ancient Mythology, especially that part of it which treats of Cushan, or Ethiopia, as it has been commonly called. He will there discover a reason for much of the obscurity and contradiction, to be found in those writers who have treated of the origin and early history of the people to whom the term of Ethiopians has been applied, in a circumstance not attended to by them. We mean, that the term Ethiopia, which is not, as is usually and absurdly imagined, a word of Greek original, alluding to the dark or burnt-like countenances of the people, but a term of sacred import, in fact a title of the chief Deity, was not confined to that region in Africa which, in modern times, has been so denominated. On the contrary, there were several countries which bore the name, in consequence, no doubt, of their inhabitants being fellow-worshippers of the same God, known to them by that appellation. We shall find, in fact, an Ethiopia in most places where the descendants of Cush or Chus, so noted for their wanderings, had taken up their abode. Thus the sacred Scriptures speak of three countries, to which the name has been given; viz. one in Arabia, on the borders of the desert, near the land of Midian and the Red Sea; the second, that which is to the south of Egypt, on the western side of this gulf; and a third, which comprehended the regions of Persia, Chusistan, and Susiana, and which was watered by the eastern branches of the river Tigris. But these were not the only countries so called; for Mr Bryant has adduced evidence, that, not only a region still farther to the east than the last mentioned, but also the Colchis of the Greeks, part of Syria and Phœnicia, Arabia Felix, Egypt itself, nay, even a district in Spain, near the straits of Gades, or Gibraltar, as it is now called, besides several other places, had obtained this appellation, and that unquestionably, for the very same reason. The original settlement of the family seems to have been in the region of Babylonia and Chaldea, from which one large branch, preserving for a long time the name of Cuseans, in honour of their progenitor, in addition to that derived from their religion, extended southwards to the country afterwards known by the name of Arabia. Another branch, for we shall not trouble ourselves with the smaller divisions, retaining also both names, but not for so long a period the latter one, and acquiring a new title from their principal occupation, viz. Auritæ, or shepherds, went into Egypt, and for a time settled in a place long afterwards denominated Goshen,—a word, most probably, derived, by a mere difference of dialect, from the term Cushan, which again is evidently very strictly referable to the boasted origin of the people from Cush, the grandson of Noah. Both Arabians and Abyssinians, it may be remarked, glory in having descended from Ham, the father of Cush. If what we have now said be correct, their mutual claim is a just one, and we have no difficulty in understanding how, in one of the most permanent characteristics of a people, that of language, they should still offer some traces of resemblance and of identity of progenitorship. The reasons why in many other respects they differ, it will be easy to assign, in few words. The Arabians were the original and the only inhabitants of the country whither they went on leaving the primitive settlement, and were, therefore, no way exposed to receive modifications of their own peculiarities of language, religion, or institutions. Whereas, the other branch was immediately brought into contact with the descendants of Mizraim, whom it found in possession of Egypt, and whose deep-rooted fastidiousness, and disdain of novelty, would, in all probability, require a very decided sacrifice of the distinguishing features of all strangers attempting an intercourse with them. Even the subsequent conquest, and long dominion of Egypt, which these people effected, could not be accomplished without very important changes in their own economy; and these, it is quite easy to imagine, must have arrived at the greatest height, when they were at last effectually opposed by the people of Upper Egypt, and obliged to abandon the country, after a cruel tyranny of nearly three hundred years duration. We conceive, then, that the people who inhabited what is properly denominated Ethiopia, are the descendants of some of those Cuseans who successfully invaded Egypt, but who were at last driven out in various directions a considerable time before the arrival of the sons of Jacob in that country.

The conjectures now stated, which it would no doubt require much room and considerable research to substantiate, will afford an easy method of reconciling some otherwise inexplicable discrepancies in the history of Abyssinia, besides accounting for several remarkable instances of similarity between them and two other nations, those of Egypt and Arabia, who were nevertheless very widely distinct from each other. But we must leave the subject for the curious reader's investigation.

The city of Axum, already spoken of, was the first which these emigrants built; and this the Abyssinians *assert*, on the authority of their traditions, to have taken place in the time of Abraham. It was from this city, that the Romans, in after times, gave the name of Axomites to the Abyssinians. Many ages elapsed from this commencement of their power, till we are furnished with any satisfactory information respecting their progress as a nation. We learn, certainly enough, that they were joined by stragglers from Egypt and other countries,—a circumstance which probably gave rise to the term Habesh, signifying 'convena,' an assemblage of different people; and that they were noted for their commerce, and its attendants, wealth and civilization. Among the doubtful, if not the impossible, events concerning them, it is sufficient to specify the conquest of their country by Moses the Jewish legislator; the visit of one of their sovereigns, viz. the person called in Scripture the queen of Sheba, to Solomon at Jerusalem, and her pregnancy by that monarch; the consequent introduction of the Jewish religion into Abyssinia; the invasion of the country by Shishak, king of Egypt; and the conquest of it by Cyrus the Great. As to these and several other incidents, which it is unnecessary to mention, we shall merely remind the reader of what we have alreay said respecting the application of the word Ethiopia, as affording a ready solution of seeming paradoxes and real absurdities.

We have evidence, though few particulars, of the conquest of Abyssinia by Ptolemy Evergetes, one of the successors of Alexander. It is still more clearly established, that the Romans, in the time of Augustus, carried their victorious armies into some of its provinces, and that Candace, the queen of Meroe, one of its chief cities, and probably the sovereign of the country, contrived to obtain very honourable terms from that prince, who, in all probability, thought its complete subjugation to be unworthy of his regard. Queens of the same name, Candace, are said to have reigned in Ethiopia for several generations. One of them is mentioned in the book of the Acts of the Apostles: Yet, it is singular, that this name is not found in any of the lists of kings of Abyssinia furnished by Mr Salt from the ancient chronicles of this people. Perhaps there is reason to think, that a very different nation from that of which we are now treating is alluded to in both these cases. In short, till about a century or two after the Christian era, the history of Abyssinia is nearly altogether unknown to us. Then, however, it begins to assume consistency. This is owing to its commercial connection with Egypt, and the introduction of the Greek language. By the former circumstance, both the people of this country, and the Arabians of the opposite coast, who had long carried on a very extensive trade with India and Africa, were brought into notice in the Roman empire; and by the latter, a medium of communication was established, which served to produce a more general attention to their transactions. But the declining affairs of the Roman empire, the great distance of this country from the seat of power, and the still vague accounts of it which prevailed, were obstacles to the production of the natural benefits to be expected from this advantage.

Abyssinia shared, however, in the effects of the conversion of Rome to the Christian faith. Accident, not design, introduced it into the former, in the early part of the fourth century. It soon took root, and pervaded every part of the government. Abyssinia became dependant on the patriarch of Alexandria, to whose spiritual labours it has almost always since proved an addition of solicitude and perplexity. Its ecclesiastical affairs, indeed, form the most interesting portion of its modern history. The reason is easily stated. In fact, scarcely any public transaction in which the Abyssinians were engaged for many centuries, had not a reference to what they, perhaps, more than almost any other people, might denominate a contention, not always very successful, for "the faith once delivered to them." Abyssinia acquired consequence with its religion; and an alliance which Justinian made with it in the sixth century, cannot be said to have demeaned that Emperor. Considerable proficiency in arts and sciences, the entire possession of the Red sea, the conquest of Arabia, may be allowed, in addition to their professing at least a kindred doctrine, to redeem the Abyssinians of this period from the imputations of savageness and insignificance. Had these advantages been permanent, or had the friendship of Rome been equalled by its ability to assist in the common cause, there is every reason to believe, that the arms of Mahomet would never have contributed to the agency of his imposture; and thus the world would have been deprived of one of the most humiliating proofs of the weakness and caprice of mankind, when assailed by a fanaticism which has both sensuality and the sword to enforce it. The exception in favour of this people, abandoned by their friends, declining in their commerce, disheartened by their calamities, as they were, is one of the most singular spectacles in history. The most expectant admirer of their resolution, however, must have failed in his hopes, had not the fortunate discovery of the passage to India, by the Cape of Good Hope, brought seasonable aid to their exertions. The immediate consequence of the arrival of the Portuguese in Abyssinia, which followed this discovery, about the middle of the sixteenth century, was a more effectual opposition to the Mahommedan power than it had hitherto experienced in this quarter. The victories of De Gama, the leader of these enterprising and warlike Europeans, secured, for a time, the peace of Abyssinia, and revived in it the languishing spirit of improvement and civilization.

The connection between Abyssinia and Portugal, it ought to be remarked, was of an earlier date than the important discovery of the practicability of doubling the southern cape of Africa; and in a great degree, indeed, it may be said to have contributed to the accomplishment of that event. There cannot be a doubt, at least, that the accounts which the priests of the former country gave, at Jerusalem and Alexandria, of the eastern regions with which their countrymen continued to trade, were instrumental in exciting the attention of the commercial states of Europe to the probability of renewing an intercourse with them, which in former times, and by another route, had been found profitable. King John II. following the example of his grand uncle, Prince Henry, the enlightened instigator and patron of those plans of discovery in which the Portuguese were at this time so eagerly occupied, was the first to take advantage of these accounts, and of the medium through which they were reported. Peter de Covilham, one of the persons sent out by him towards the east, in search of more particular information, having gone from Alexandria to Cairo, Suez, and Aden, sailed thence across the Indian ocean, and reached Calicut on the coast of Malabar. On his return to Cairo he was met by two Jews, whom the king, with his usual foresight, had ordered out with fresh instructions. One of these carried home the account of the observations he had made during his interesting expedition; and, with the other, Covilham set out from the island of Ormus, in the Persian gulf. Thence he returned to Aden, and ultimately arrived in Abyssinia, where he was well received by the Emperor Alexander, and elevated to very important state offices. To his judicious communications during the long residence he made in this country, which commenced about 1490, we must ascribe the encouragement the Portuguese received to prosecute their efforts towards discovery; whilst, on the other hand, his advice, in some critical emergencies, induced the Abyssinians to have recourse to an alliance with that power, as alone capable of retrieving their affairs from the ruin that threatened them. An embassy to the Court of Lisbon, under Matthew, an Armenian, was graciously received. A return was made in 1520; and thus was effected a direct intercourse between the two countries, which promised the most important results to both.

A just opinion of their superiority, enhanced by gratitude for considerable benefits, secured the attachment of the Abyssinians to their European allies. Probably this had been consolidated by a scrupulous regard being shewn, on the other part, to their ancient prejudices, which would certainly almost have given way to the lenient influence of moderation and a respected example. It was undoubtedly impolitic and unreasonable afterwards to condemn and anathematize the minor differences of a creed, which, when first discovered, had been in general considered a cause of the greatest exultation. Such, however, was the conduct of the Portuguese. Their admiration of the Abyssinian faith, which operated so essentially to the interests of this country, when first visited, was speedily converted, by an unrelenting bigotry, into a source of the most absurd and oppressive exactions. These could not be made palatable, even by the insidious arts, or the useful favours, with which the Jesuits, who were appointed to the labour, sought to add new lustre to the spiritual triumphs of Rome. When pressed by difficulties, or threatened by calamity, the emperors would promise obedience as an essential condition of the assistance required. But performance was a tardy follower on the relief obtained. In a few instances, indeed, the vows which distress extorted were kept when it was removed; and, on one occasion, especially, a Catholic patriarch had the satisfaction to receive the homage of an Abyssinian monarch, and his abjuration of the Alexandrian faith.

For similar and still greater success, the really meritorious Paes was indebted, not less to the extreme prudence and consideration which he had exhibited since his arrival in this country, about 1600, than to the immense superiority which the Jesuits, whom he employed in a controversy, displayed over their feeble opponents, the native priests. The people, however, were far less docile, and seemed in general to be insensible alike to the painful instructions of experience and the policy or devotion of their monarchs. Tumults, rebellions, and bloodshed, testified their abhorrence of the novelties attempted to be imposed on them, and their full and invincible determination to believe and to worship as their fathers had done. Extermination seemed the only measure fitted to accomplish the views of the frantic and obstinate Mendez, who succeeded Paes in the patriarchate; and to this, apparently, neither the disposition of his heart, nor the suggestions of his judgment, presented any obstacle. The army, however, paused in the work of destruction; and the infatuated emperor, Socinios, had the misery to survive the slaughter of his subjects and the universal resistance of his impious decrees. An act of toleration, the re-establishment of the ancient religion, and the resignation of the crown to his son, which were the last measures of his reign, were the surest tests of the madness by which it had been actuated, and of the extreme fallibility of Popes and Jesuits in directing the affairs of his kingdom.

Facilidas, his successor, pursued a different line of conduct, though, in one respect, the resemblance was obvious. The principle of intolerance, in fact, was the same in both, but the objects on which it was exercised had varied. Mendez and his brethren were ordered to leave the kingdom, but delaying their departure, were either executed or sold as slaves; and the Roman Catholics, throughout Abyssinia, were commanded, on pain of death, to renounce their religion. This does not seem, on the whole, to have proved a very difficult task, and few persons availed themselves of the opportunity of martyrdom which it afforded. Some feeble attempts were occasionally made by other missionaries, during this reign, to introduce or revive the faith of the Romish church; but they were uniformly unsuccessful. Thus, then, may be said to have ended a contest for religion that had lasted upwards of a century; and, to use, with some modification, the words of the eloquent Gibbon, "the gates of this solitary realm seemed for ever shut against the arts, the sciences, and the fanaticism of Europe."

The disorder brought on by these impolitic efforts to subvert the popular faith, was not confined to the period in which they were made. The whole machine of government became deranged; irregularity and confusion marked all its operations; fear and distrust pervaded all ranks of the people; and usurpers and aliens seized upon the throne. Factions and revolutions within, and the attacks of barbarous neighbours, fill up the remaining history of this unfortunate kingdom, and seem naturally enough to have proceeded from this disorganizing cause, though its influence was long overlooked in the abundance of newer dissentions. The arrival of missionaries from the same church, in 1751, revived its memory. Impelled by the same zeal, they commenced their labours in the same manner, operating on the hopes and fears of the emperor and his court. But all their exertions were fruitless, and ended in equal disappointment, from the reluctance and aversion of the people.

Of the complete failure of this perhaps final effort of the "Propaganda," notwithstanding its early promise on royalty at least, the reader will find a translation of an interesting document in Mr Salt's appendix. Mr Bruce, who has drawn up an able summary of Abyssinian history, does not appear to have been acquainted with this production, though an observation in his original memoranda alludes to an event corroborative of its contents. To the works of these enterprising travellers, we must necessarily refer for information respecting the minuter particulars of Abyssinian history.

Before concluding, however, we shall make a few remarks on the present posture of affairs in this distracted country. The chief of Amhara, when Mr Salt left Abyssinia, was Guxo, who originally had the command over Begemder and the eastern provinces only, but who had greatly enlarged his dominions by the conquest of Damot and Gojam. This rendered his power absolute on the western side of the Tacazze, and his recent connexions with the southern Galla have served to confirm it. He is said to be able to bring 20,000 cavalry into the field; but this force, which constitutes the main part of his army, is inadequate to offensive war against Tigré, although quite sufficient for the defence of the conquests he has already made. It is probable, however, that no long time may elapse, ere the Galla, in union with him, shall have acquired strength enough, not only to overrun the provinces of Shoa and Efat, already detached from Tigré, but also, by the conquest of that state itself, to complete the subjugation of the kingdom. The reduced and daily weakening condition of the government rendered such an event extremely probable previously to Mr Salt's visit; and it is obvious from his account, that, unless some friendly aid be given, no effectual struggle can much longer be made to restore the ancient splendour of Abyssinia, or to prevent it from passing into the list of extinct empires. How far this is to be lamented we shall not conjecture; but that almost any assistance, however small, on the part of the British government, might prove available against its occurrence, seems fairly enough to be inferred from the effect already produced by that gentleman's visits, in augmenting the consequence of Tigré, and giving it a preponderance over the other states. The possession of two small field-pieces, which he was directed to take as a present to the Ras, and which he was fortunate to convey in safety, notwithstanding many difficulties, will enable that chief to retard the threatening fate of his country. But he would require still greater help to secure its independence, or to establish its dignity. The principal obstacle to such assistance is, the want of communication with the coast of the Red Sea, through which alone any intercourse with Abyssinia can be conveniently carried on. Besides the intervention of the Dumhoeta, and other tribes, Massowah and Suakem, two considerable ports, offering the easiest access to it, are at present possessed by the deputies of the rulers of Jidda, whose exactions and unfriendly conduct prevent merchants from carrying on any steady or profitable commerce with this region. It is not to be doubted, however, that a respectable force under the British flag, already so dreaded, would easily accomplish any purpose which it might be necessary to put into execution. Mr Salt argues for this measure as essential to the safety of our Indian possessions, which he thinks threatened, though surely with very remote danger, by the increase of power on the part of these hostile rulers. They are said already to command both sides of the gulf, by several armed ships of four and five hundred tons burden, besides having a fleet of *dows*, carrying each from six to eight guns, and manned by the desperate ruffians composing the population of Jidda. Without going the length of Mr Salt's apprehensions, we concur in opinion as to the advantages of at least protecting some port on the Abyssinian coast. The important benefits resulting to the Abyssinians from this measure, would undoubtedly bequeath on them the debt of gratitude; still, however, a new and probably large demand for English and Indian goods, the acquisition of a cordial ally to watch over our interests in a quarter where danger has been suspected, not to speak of the satisfaction arising from generosity towards an ancient Christian power, reduced to implore our kind offices,—might prove amply remunerative of any expence or trouble which we bestowed on the enterprise. It is no doubt gratifying to think, that the arduous contest in which we have so long been occupied, has not altogether prevented the attention of our government to this very interesting point. The mission of Mr Salt, with a present from our Regent, may be allowed to form the basis of some hope in behalf of Abyssinia. And now, (August 1815,) that our efforts have ended so gloriously for our arms, it is reasonable surely to think, that still greater regard will be shewn to the superstructure. If so, the suggestions of Mr Salt, we have no doubt, will be effectually adopted. The most complete success may be anticipated; and we should have another, and perhaps not the least pleasing instance, in this most extraordinary age, of the power and liberality of Britain in restoring the ancient order of kings! Far be it from us to applaud such efforts, if our national morality were to be violated in their display, or if even hostile powers should have the slightest grounds to charge our interference with selfishness or dishonesty. But the apprehension seems unnecessary. We, at least, are convinced, that the conduct, which, on political grounds, it would be prudential in our government to adopt in this case, may be defended on principles strictly recognizing the rights and the real interests of every other power that might happen to be concerned in its success. On the whole, perhaps, the reader will agree with us, that the Abyssinians want neither inclination nor ability to become a powerful people, and that the untoward political circumstances with which they have long contended, rather than any deficiency of character or unkindness of nature, prevent them from sharing in the benefits which free intercourse, and the cultivation of mutual interests confer on more fortunate nations. Separated as she now is from the sea, shaken by internal convulsions, and beset on all sides by malignant rivals, Abyssinia, nevertheless, is able, by the warlike spirit of her people, the intelligence of her chiefs, and the remains of an emulation, which was formerly indeed more successful, to command respect and forbearance from her hostile neighbours. She is still of consequence, therefore, in the scale of nations, and could scarcely disparage any power that might incline to make her greater. The experiment would at least be meritorious, and would hazard little. Who knows, but that, in after times, its results may be registered amongst the brightest examples of British beneficence and policy?

ACACIA, is the trivial name of several plants, the flowers of one of which are employed by the Chinese in painting on paper, and in communicating a beautiful and durable yellow to cloth. The same word denotes the extract, or inspissated juice, obtained from the *Mimosa Nilotica*; and a similar preparation from unripe sloes, which is sometimes employed as a substitute, is called *German acacia*.

ACACIA, a name which has been given to the figure of a roll, or bag, in the hands of consuls and emperors, which is represented on ancient medals. It is supposed by some to be a handkerchief rolled up, with which signals were made at the public games; or, according to others, it is a purple bag filled with earth, which was carried by some of the consuls and emperors, as an emblem or memorial of their mortality.

ACACIUS, ST. bishop of Amida, who flourished about the year 420, and was greatly distinguished by his charity and humanity; a remarkable instance of which is recorded, in the redemption of 7000 Persian slaves, who were perishing with hunger, at the expence of the church plate, which was sold for this beneficent purpose. When they returned in safety to their own country, Veranius, their king, was so impressed with this noble act of the humane and generous bishop, that he anxiously desired to see him. An interview too place, and produced the happy effect of establishing a peace between the Persian prince and Theodosius I.

ACADEMICS, the name by which the disciples of an ancient school of philosophy are distinguished. Socrates was the founder of this philosophy; and Plato first established a school for teaching it, in a garden, or grove, near Athens, which had been bequeathed to the citizens by a person of the name of Academus, for the purpose of gymnastic exercises; and hence the school was called the *Academy*, and its disciples *Academics*. Three periods, characterized by the diversity of doctrine which prevailed, mark the progressive history of this celebrated school, and have received the distinctive appellations of the *Old*, or *Ancient*, the *Middle*, and the *New* Academy.

Plato, and his immediate successors, ascribed the difficulties which oppose the discovery of truth, not to the nature of things, but to the imperfection of the human faculties, and therefore recommended modesty and diffidence, caution and circumspection, to those who would successfully pursue it; and while this method of acquiring knowledge was followed, the school was denominated the Old or Ancient Academy. But new teachers arose; and, disregarding the sound maxims and cautious mode of procedure inculcated by Plato, introduced subtleties and refinements formerly unknown in his system. At the head of these innovators was Arcesilaus, who assumed it as a principle, that no difference existed between truth and falsehood, or, at least, that it could not be discovered. He rejected the testimony of the senses, and the authority of reason. Those who adopted this sceptical philosophy are known by the name of the *Middle Academy*. When Carneades, a native of Africa, was placed at the head of the Platonic school, he abandoned the more absurd and obnoxious opinions of Arcesilaus, and introduced various modifications into his doctrine. He and his followers, one of whom, Philo of Larissa, is celebrated by Cicero for his learning, eloquence, and attractive manners, constituted the *New Academy*. Antiochus was the last teacher of this school during its establishment at Athens; and after his resignation, in the 175th Olympiad, the groves of Academus were disturbed by the horrors of war, the professors were dispersed, and the school itself was removed to Rome.

ACADEMY, in modern times, is used to denote a society of learned men established for the improvement of arts and sciences; and it is also applied to public and private seminaries for the instruction of youth. For an account of Academies of both descriptions, as well as of associations for similar and other purposes, under the name of Society, see INSTITUTION.

ACANTHUS, or BEAR'S BREECH, a genus of plants belonging to the class *Didynamia*. The same word is sometimes used to denote an ornament, resembling the leaves of a species of acanthus, on the capitals of the Corinthian and Composite orders of architecture.

ACAPULCO, a seaport town of Mexico, situated on a bay of the Pacific ocean. It is distinguished by the name of a city, although an inconsiderable place, and containing only about 400 families, chiefly composed of negroes, mulattos, and Chinese. The houses are ill constructed, and generally thatched. The climate is extremely sultry; and the air being frequently loaded with vapours, is insalubrious. On this account the Spanish inhabitants retire from the coast, excepting when business requires their attendance during the arrival of the ships from the islands in the Pacific ocean. The productions of the surrounding country are cotton, maize, fruits, and tobacco. Cattle and sheep are also abundant. The harbour of Acapulco is commodious and extensive, and capable of receiving 500 ships. It is defended by a fort, furnished with a small garrison, and mounted with large cannon. The trade of Acapulco is considerable. A ship sails annually to Manilla, and another returns loaded with the rich productions of the East. The arrival of the Chinese ship, or galleon, presents a new scene. Merchants come from most parts of South America, but chiefly from the provinces of Mexico, and form an extensive encampment in the vicinity of the town, for the conveniency of exchanging cochineal, European toys, and nearly half a million Sterling of silver, for precious stones, Persian carpets, silks, muslins, drugs, spiceries, tea, and gold works. A large proportion of the goods brought by this ship are conveyed to Mexico on the backs of mules and horses; from thence they are carried to Vera Cruz, to be shipped for Europe. Acapulco was taken and plundered in 1580, by Sir Francis Drake. N. Lat. 17° 10', W. Long. 101° 40'.

ACARNANIA, an ancient country on the Ionian sea, separated by the river Achelous from Ætolia, and from Epirus by the gulf of Ambracia. It was a free state, governed by a prætor, with other subordinate magistrates. The inhabitants are represented as an effeminate and dissipated race, but remarkably jealous of their liberty, as well as inflexibly faithful in observing their treaties. As the Acarnanians were strongly attached to Philip, king of Macedon, every attempt was made by the Romans to seduce them from their fidelity. Leucas, their capital, being betrayed by some Italian exiles into the hands of Lucius Flaminius, this event so intimidated the whole country, that the cause of Philip was universally abandoned, and the people remained under the protection of the Romans till the fall of Corinth, when their country formed a constituent part of Achaia. Their year, it is said, consisted only of six months. The modern name of this country is la Carnia.

ACARUS, the Tick, or Mite, a genus of insects belonging to the order *Aptera*. See ENTOMOLOGY.

ACATALECTIC, in *Prosody*, denotes such verses as have all their feet or syllables complete.

ACATHISTUS, a solemn hymn, or vigil, sung in the Greek church, on particular occasions, in honour of the Virgin, for having thrice delivered Constantinople from the invasions of the barbarous northern nations. The term signifies *without sitting*, because the people stood while they celebrated this festival.

ACCAIA, otherwise called *Laurentalia*, were solemn festivals celebrated by the Romans in honour of *Acca Laurentia*, the nurse of Romulus, the founder of their city.

ACCELERATION, signifies the increase of velocity, or the continued accession of velocity in falling bodies, or in bodies passing along an inclined plane, or moving round a fixed centre. See MECHANICS.

ACCELERATION *of the Moon*, is the increase of the moon's mean motion, compared with the diurnal motion of the earth. See ASTRONOMY.

ACCELERATION *of a Planet*, is, when its real diurnal motion exceeds the mean diurnal motion. This inequality arises from the change in the planet's distance from the sun, which is continually subject to variation, the velocity of the planet being accelerated in that part of its orbit which is nearest to the sun. See ASTRONOMY.

ACCELERATION *of the Stars*, is the difference of time between the diurnal revolution of the sun, and the diurnal revolution of the fixed stars, by which they rise and set 3′ 56″ sooner daily. See ASTRONOMY.

ACCENDONES, or ACCIDONES, the name of certain persons among the Romans, whose office it was to excite and animate the gladiators and combatants, in their public exhibitions. The term is derived from a word which signifies to *kindle* or *inflame*, or from another, which signifies to *approach*, or *come near to*.

ACCENSI, in the Roman armies, were the supernumerary soldiers, intended to supply the places of those who were wounded or slain in battle. They were chosen from the fifth class of citizens, and being considered raw troops, were placed in the rear of the army.

ACCENSI, an inferior order of officers, who attended the Roman magistrates, called assemblies of the people, and summoned parties to appear before the judges.

ACCENT, in *Grammar*, is a particular character or mark put over a syllable, by which the management of the voice, in pronouncing it, is to be directed. The Greeks and Romans employed three characters for this purpose, and were the same with those which are used in Britain, viz. the *acute accent* (′), by which an elevation of the voice is marked; the *grave accent* (‵), which denotes a depression of the voice; and the *circumflex accent* (˜), which being composed of the two former, and originally marked thus (ˆ), denotes first an elevation and then a depression of the voice.

ACCENT, in *Music*. Such parts of a bar are said to be accented, as naturally receive the emphasis or expression, whether of the voice or of instruments.

ACCESSION, in *Law*, a mode of obtaining property in things closely connected, or dependent on each other, as in the case of the proprietor of the soil having right to its productions, the proprietor of cattle having right to their offspring, and the proprietor of land on the sea-shore, or on the banks of a river, having right to any additions to that land by the deposition of soil. This is distinguished by the name of *natural accession*. In the case of artificial additions to land, as in building houses, and planting trees, such houses or trees belong to the proprietor of the land, and not to the person who built or planted them. This is called *artificial accession*.

ACCESSION, among *Physicians*, is employed to denote the paroxysm of a disease; while politicians apply it to the succession of a prince to the throne, on the death of his predecessor.

ACCESSORY, or ACCESSARY, in *Common Law*, denotes a person guilty of a felonious offence, not actually or primarily, but by participation, such as by concealing, advising, or commanding. An accessory, before the fact, is one who prevails with another to commit felony, though not present at the perpetration of the deed; or he who receives, assists, or comforts any person guilty of murder or felony, of which he has a clear and distinct knowledge. But all concerned in rioting, mobbing, and similar offences, and in the highest species of crimes, as high treason, are regarded as principals.

ACCESSORY NERVES, in *Anatomy*, two nerves which arise from the spinal marrow of the neck, and are distributed to the muscles of the neck and shoulders. See ANATOMY.

ACCIDENT, in general, denotes any casual event. Among *logicians*, it is used for whatever is not essential to a thing, as a man's money or clothes; for such properties in any subject as do not essentially belong to it, as whiteness in paper; and all qualities indiscriminately are termed accidents, in opposition to substance, as hardness, bitterness, smoothness, &c.

ACCIDENT, in *Grammar*, denotes any property of a word which is not essential to the definition of it. Whatever its meaning may be, it is either primitive or derivative, simple or compound, which are said to be its accidents. So the accidents of a noun are gender, number, and flection, and the accident of an adjective is comparison. See GRAMMAR.

ACCIDENTAL COLOURS, are those which are produced by the continued action of light upon the eye. If a small square of red paper be placed upon a white ground, a border of light green, surrounding the red square, is perceived. If the eye be removed from the red square, and directed to another part of the white ground, a square of light green, inclining somewhat to blue, and of the same size with the red square, is distinctly perceptible. This imaginary green colour is the accidental colour of the red; and its impression remains upon the eye, till it is effaced by impressions from other objects. Buffon, who first prosecuted this curious investigation, made similar experiments with squares of different colours, all of which were placed on a white ground, excepting the white square, which required a black ground; and he found that black is the accidental colour of white; white, that of black; red, that of blue; purple, that of green; blue, that of yellow, and green, that of red.

ACCIPENSER, or STURGEON, a genus of fishes belonging to the order *Cartilaginei*. See ICHTHYOLOGY.

ACCIPITER, signified, among the Romans, a hawk, which was regarded as a bird of a bad omen, on account of its being extremely carnivorous; although we are informed by Pliny, that in the case of marriage it was looked upon as a bird of a favourable omen, as it never devours the hearts of other birds, thereby intimating, that no differences in the connubial state ought to reach the heart. It was worshiped as a deity by the inhabitants of Tentyra, an island in the river Nile.

ACCIPITRES, the first order of birds in the system of Linnæus. See ORNITHOLOGY.

ACCLAMATION, a confused noise or shout, is the manner in which the public usually express their approbation or applause; but, in a more limited acceptation, it denotes a certain form of words, uttered with great vehemence, and in a kind of musical tone. Acclamation is distinguished from applause; the former is an expression of approbation by the voice, the latter by the hands. Applause was only bestowed on those who were present, and it was confined to men; but acclamation was given to the absent, and sometimes extended to women; and it was often accompanied with applause.

Acclamations formed a remarkable feature in the manners of the ancients, and they were of different kinds, as nuptial, military, theatrical, &c. In the nuptial ceremonies of the Greeks and Romans, acclamations were exhibited on the evening of the marriage, and the morning after, in the form of songs, in which the praises of the newly-married party were celebrated. Military acclamations were employed by the Roman armies at the election of their commanders; and in the moment of engaging the enemy, they shouted out, *Victory!* A similar practice obtained among the Greeks; and, it may be added, has prevailed both among ancient and modern nations. At the conclusion of a war, the victorious army extolled the praises of their leader; and on the return of the army, while they proceeded to deposit in the capital the spoils they had taken, their acclamations were re-echoed by the citizens. The theatrical acclamations of the Romans, which, in the earlier ages of the Commonwealth, were simple expressions of approbation and applause, became afterwards confused and disorderly shouts, and were at last converted into a kind of regular concert. This form of musical acclamation was known in the time of Augustus; it was greatly improved by Nero, who seems to have appointed a master of his band, which consisted of 5000 soldiers, who, on a given signal, began to chant his praise, which was repeated by the spectators. Acclamations were also given to the children of emperors, to favourites, and magistrates who presided at the public games. Similar expressions of approbation and applause were introduced into the Roman senate, and were exhibited on account of the election and proclamations of the emperors. Among both Greeks and Romans, it was not unusual to hold public assemblies, to hear the works of their poets and other authors recited; and those who were anxious for reputation had measures preconcerted that the acclamations should be loud and general. The solemn assemblies of the church were not exempted from this tumultuous manner of expressing approbation; but the violation of the solemnity usually attached to religious duties was at last suppressed.

It is quite unnecessary to add, what is known to every reader, that the different kinds of acclamation, excepting the last, are very prevalent in modern times—so prevalent, indeed, that they seem to form an essential part of many of our popular assemblies.

ACCOLADE, a certain ceremony, anciently observed in conferring knighthood; but concerning its precise nature, the opinions of antiquarians are not agreed. While some suppose, that it signified the embrace or kiss which princes gave to the new knight, as a mark of regard, and hence the origin of the word, which implies embracing, or taking around the neck,—others think, that it means a blow on the chine or back part of the neck, on the same occasion. The kings of France, in the early part of the history of that nation, conferred the gilt shoulder belt, by kissing the knights on the left cheek. The blow was in use among the ancient Normans. In this manner, William the Conqueror conferred the honour of knighthood upon his son. The blow was, at first, given with the naked fist, for which a stroke with the flat side of a sword was afterwards substituted.

ACCOMMODATION, is the application of one thing or event, by analogy, to another, in which some real or supposed resemblance exists. This term is chiefly applied to the interpretation of one part of Scripture by means of another; and, as might be expected, commentators are by no means agreed to what extent this principle of accommodation ought to be carried in the explanation of sacred history. According to the views of some authors, a prophecy of Scripture is said to be directly fulfilled, when the event foretold actually happens; and it is said to be indirectly fulfilled, when an event happens to any place or people similar to what befel another at a former period. In this latter sense, the prophecy or passage containing it referred to, is said to be applied by way of accommodation. An example of this kind is taken from the words of Isaiah, which were spoken to the people of his own time, and are said to be fulfilled in those who lived in the time of our Saviour, and are accommodated to them: "Ye hypocrites, well did Isaias prophecy of you, saying, This people draweth nigh unto me with their mouth, and honoureth me with their lips, but their heart is far from me." The same words were afterwards addressed, or accommodated by St Paul, to the Jews of his time. It has been asserted by some, that the rites and observances of the ceremonial law were of Egyptian origin, and were thus accommodated by Moses to the peculiar views and modes of thinking among the Israelites; and it is farther asserted, that the primitive church applied or accommodated many Jewish and heathen ceremonies to the system of Christian worship.

ACCOMPANIMENT, in *Music*, denotes the instruments which accompany a voice in the performance of any composition, to add to its general effect. Accompaniments are employed on the stage, as well as in the choir, and in recitative as well as in song. In modern times, the accompaniment is a different part from the song. Accompaniments were likewise employed among the ancients; and, in the theatre, it would appear that a different set of instruments was adapted to the chorus from that which accompanied the recitative. It is generally supposed, that the ancient accompaniment consisted only in playing in octave; although some think that a passage in Plato implies that actual symphony, or music in parts, was performed.

ACCOMPLICE, a person who is associated with another in the commission of a crime. By the general rule of law, the accomplice is subjected to the same punishment with the principal offender; and, according to the law of Scotland, his evidence against associates is not admitted, excepting in cases of treason, secret crimes, and some others, which are specified in the statute; but to remove every motive to give false testimony, he receives a full pardon before his evidence is required.

ACCUBATION, derived from a word which signifies to *lie down*, is a posture of the body, between sitting and lying, and it is generally applied to the posture of the Greeks and Romans at meals. It was introduced by the Greeks, and from them was adopted by the Romans; for, in the earlier periods of the republic, this practice was unknown. A Roman meal was conducted in the following manner: A low round table was placed in the dining-room, and around it two couches, called *biclinium*, or three, *triclinium*, were arranged. These couches were covered with a kind of bed-clothes, and furnished with quilts and pillows, for the accommodation of the guests. Three persons usually reclined on each couch. They lay on their left sides, with their heads on the pillow, or on the left arm, while the back was supported by cushions. The head of the second was placed near the breast of the first, separated by a pillow; and the third person was in the same relative situation with the second. The middle place was regarded as the most honourable. Before the guests came to table, they put on a dining garment, and pulled off their shoes or slippers, that the couch might not be soiled.

ACCUSATION, a charge brought against a person supposed to be guilty of some crime, at the suit of a private individual, or of a public prosecutor. Among the Romans, there was no public prosecutor; private persons, whether aggrieved or not, or otherwise interested, might prosecute for public crimes. In Britain, all accusations for public crimes are made at the suit of the crown, or of private parties who are interested or aggrieved. According to the English form of criminal procedure, the case of a person charged with a crime is investigated by the grand jury before he is put upon his trial. This form of proceeding is only observed, in Scotland, in cases of high treason. In all others which come before the supreme criminal court, the Lord Advocate is the public prosecutor, and in the inferior courts the procurator-fiscal; and if they should think proper to decline to bring the accused to trial, the private party aggrieved, with the concurrence of the public accuser, which must be granted, may institute a criminal action. See Law.

ACCUSATIVE, is the fourth case of Latin nouns, by which the termination of motion or action, or the connection between the agent and the object acted upon, is expressed. Thus, *Ille amat Deum*, He loves God; in which the action of loving proceeds from the agent, and terminates in, or is exerted towards God. See Grammar.

ACEPHALI, from a Greek word, signifying *without a head*, is the denomination of certain heretical sects who had no head or leader. These sects appeared in the fifth century. Some maintained that the body of Christ was incorruptible before the resurrection; others held a contrary opinion; and, while some asserted that there are three distinct natures in the Trinity, others believed that our Saviour was ignorant of some things. Each of these sects was characterised by distinctive appellations. A similar denomination was given to bishops who were exempted from the jurisdiction of their patriarch.

ACER, the maple or sycamore tree, a genus of plants belonging to the class Polygamia.

ACERRA, in *Antiquity*, denotes an altar which was constructed by the Romans in the apartment of a person deceased; and, on this altar, incense was burned till the time of burial. The original intention of this custom, it is supposed, was to conceal or destroy infectious smells; but it seems to have been converted into an expensive funeral ceremony; for, by the laws of the twelve tables, the practice is prohibited. The same word corresponds with *thuribulum* and *pyxis*, and denotes the small pot in which the incense and perfumes were burnt. It corresponds also with the *censer* of the Jews, and the *incense-pots* of Roman Catholics.

Among the Chinese, a custom similar to that of the Romans prevails at this day. A room is decorated with mourning; an altar is erected, on which the image of the deceased is placed; and all who approach to it bow four times, and offer oblations and perfumes.

ACETATES, in *Chemistry*, are salts formed of acetic acid and alkaline, earthy, or metallic bases. See Chemistry, *Index*.

ACETIC ACID, in *Chemistry*, a production of vegetable fermentation, corresponding with radical or distilled vinegar, and existing ready formed in some plants. See CHEMISTRY, *Index*.

ACHÆANS, a people of Greece, who inhabited ACHAIA *propria*, a district or province of Peloponnesus. The name is derived from Achæus, the son of a king of Thessaly, who was exiled from his own kingdom, and fled to Laconia, a province of Peloponnesus. His descendants drove the Ionians from Achaia, and seized their kingdom, which consisted chiefly of twelve cities, with no large revenues, and no great extent of territory. A republican form of government was established, wise laws were framed, and their administration was entrusted to upright and prudent magistrates. Firm, and united within itself, feared and respected by its neighbours, this small state continued to flourish and preserve its liberty and independence till the time of Alexander the Great, when it was distracted and weakened by jealousies and political dissensions, and became an easy prey to a foreign yoke, or a fit subject of oppression to domestic tyranny.

In the 280th year before the Christian era, when Pyrrhus invaded Italy, the Achæans recovered their independence; the tyrants were banished, the ancient league was renewed; new states were united under it; and the whole of Greece, excepting the Lacedæmonian territory, included. A public council or assembly was formed, consisting of deputies from each state, and met twice annually for the purpose of managing the affairs of the commonwealth. The president of this assembly was the commander of the army.

The Lacedæmonians, the rival neighbours of the Achæans, were the first to disturb their tranquillity. To resist their power, they were forced to form an alliance with Philip, king of Macedon, by whose aid they were successfully supported, and peace was established. But when the Achæans declined to promote the ambitious views of the Macedonian monarch, he became their determined enemy. This conduct led them to form an alliance with the Romans against Philip; and when the war was finished, they obtained possession of Corinth, and were again permitted to resume their ancient constitution. Nine years afterwards, the city of Lacedæmon was conquered, and became part of the Achæan confederacy. The Achæan state was now the most powerful of any in Greece, and it was greatly respected by all surrounding nations. But it was soon after disunited and enfeebled by internal dissensions; and becoming an object of jealousy to the ambitious views of the Romans, it was invaded by that people. In the 146th year before the Christian era, Mummius, the Roman general, defeated the Achæans, and plundered and burnt the rich city of Corinth; soon after which the celebrated confederacy was dissolved, and Greece became a Roman province.

ACHAIA, a name under which early writers and poets seem to have included the whole of Greece. In the times of the Roman state, this name was applied to the whole territory which constituted the Achæan league; when that league was dissolved, Greece was divided by the Romans into two provinces; one including Macedonia and Thessaly, and the other Achaia, which comprehended all the other states of Greece. Achaia Proper is limited to a small district of Peloponnesus, extending westward along the bay of Corinth, and bounded by the Ionian sea. The modern name is *Romania Alta*.

ACHEEN, ACHE, or ACHEN, a kingdom in the north-west of the island of Sumatra. See SUMATRA.

ACHILLÆA, yarrow, milfoil or sneezewort, in *Botany*, a genus of plants belonging to the Syngenesia class.

ACHILLEID, or ACHILLEIS, the name of a poem, in which the author, Statius, proposed to celebrate the life and adventures of Achilles; but he died before he proceeded farther than the infancy and education of his hero.

ACHILLES, one of the most celebrated heroes of ancient Greece, was the son of Peleus and Thetis, and was born at Phthia in Thessaly. Innumerable fables are related of this hero. To render him invulnerable, his mother immersed him in the river Styx; and it was expected that no wound could be inflicted, excepting on the heel by which he was held; but this supposed charm was not effectual, for he was wounded in the arm by a lance, in battle with the Trojans. Achilles was entrusted to the care of the centaur Chiron, to be instructed in horsemanship and martial exercises; and, to fit him to bear toil and fatigue, he was fed with honey, and the marrow of lions and wild boars. His mother, Thetis, endeavoured to keep him from the siege of Troy, by disguising him in female apparel, and concealing him at the court of Lycomedes. He was discovered by Ulysses, and persuaded to follow the Greeks, among whom he greatly distinguished himself by his bravery and heroism; but being disgusted with Agamemnon for the loss of Briseis, retired from the camp, and nothing could rouse him but the spirit of resentment to revenge the death of his friend Patroclus. In an engagement with the Trojans, he slew Hector, and dragged the dead body, fastened to his chariot, thrice round the walls of Troy. While Achilles was in the temple, treating about his marriage with Philoxena, the daughter of Priam, he was wounded in the heel by Paris, of which wound he died, and was buried in the promontory of Sigæum. After the fall of Troy, in obedience to the dying request of Achilles, the Greeks sacrificed Philoxena on his tomb, that he might enjoy her company in the Elysian fields. When Alexander the Great visited the tomb of Achilles, he placed a crown upon it, in honour of the Grecian hero, and said, "Achilles was happy in having, during his life, such a friend as Patroclus, and, after his death, a poet like Homer." The death of Achilles happened about 1183 years before the Christian era.

ACHMIM, the ancient Chemmis and Panopolis, is a celebrated city of Upper Egypt, and is situated on the eastern bank of the Nile. Abulfeda, a writer in the beginning of the fourteenth century, describes Achmim as a large town, and its immense temple as one of the most splendid monuments of antiquity. This temple, the ruins of which afford ample proof of its former magnificence, is without the limits of the present town. The stones of which it was constructed were of enormous size. Some have been removed to be employed in the construction of a mosque, some are heaped up in the squares of the town, and others, whose magnitude has defied the efforts of modern ingenuity to displace them, remain as a memorial to distant ages of a spot which the sublime genius of ancient architecture had rendered sacred. Many of the stones are covered with hieroglyphic figures. On one stone, four concentric circles are inscribed in a square. The innermost circle contains the figure of the sun; the next circle is divided into twelve parts, on which twelve birds are represented; the third, divided in the same way, exhibits the figures of twelve animals; and on the fourth, which has no divisions, twelve human figures appear. M. Savary, from whom this description is taken, supposes that these divisions and figures represent the twelve months of the year, and the twelve signs of the zodiac; and this seems probable, from the Egyptians being the first who thus divided the year. The angles of the square are occupied by the four seasons, and on each side is seen a globe with wings. The French traveller thinks it probable, that this temple was dedicated to the sun, and that the whole of the hieroglyphics mark his passage into the signs of the zodiac, and his annual revolution.

Achmim is at present under the dominion of an Arab prince; and, though greatly circumscribed in extent, the streets are spacious and clean, and a regular police is established. Agriculture and commerce are prosperous, and the manufacture of cotton stuffs and pottery is considerable. But the most extraordinary object of the traveller's attention, is what may be denominated the serpent establishment, for the cure of diseases. More than one hundred years ago, Scheick Haridi died at this place, and was so much venerated for his sanctity by the Mahometans, that they erected a splendid monument to his memory, to which people flocked from all quarters, to offer up prayers. A priest, taking advantage of their credulity, persuaded them that Haridi's soul had entered into the body of one of those harmless serpents, which are abundant in the country. He taught it to obey his voice, and to perform wonderful tricks, and at last pretended to cure all diseases. The serpent was confined to the tomb of Haridi, and produced only on proper occasions. The priest who had established this lucrative trade, found successors who were equally disposed to persevere in it, and who saw the advantage of impressing a belief of the serpent's immortality, of which they ventured to exhibit a public proof. The serpent was produced, and cut in pieces, in presence of the Emir, and placed for two hours under a vase; and when the vase was removed, a serpent, exactly the same in size and colour, appeared. This miraculous event was spread abroad, greatly increased the reputation of the serpent, and attracted crowds of suppliants. When the serpent appears at the bottom of the tomb, and approaches the suppliant, it is regarded as a sign that the disease will be removed; but it is understood that a present has been previously offered, and is expected to be proportioned to the rank and wealth of those who solicit the serpent's healing influence.

ACHRADINA, one of the four cities or divisions of Syracuse, is represented as the most extensive and most beautiful part of that celebrated city. The public buildings were of the most magnificent description, among which are enumerated the forum, with its splendid porticos; a prytaneum of remarkable elegance; a spacious senate-house; and a superb temple, dedicated to Jupiter Olympius.

ACHRAS, or SAPOTA PLUM, a genus of plants belonging to the Hexandria class.

ACHROMATIC, a Greek word, which is expressive of want of colour, is a term applied to telescopes which are so constructed as to remedy the aberration of the rays of light, whether it arise from the figure of the lens or speculum, or from the unequal refrangibility of the rays. See OPTICS.

ACIDS, in *Chemistry*, an important class of substances, which, when applied to the tongue, excite the sensation called *sour*; which change the blue colours of vegetables to red; unite with water, almost in all proportions; and combine with alkalies, earths, and metallic oxides, forming compounds which are denominated *salts*. See CHEMISTRY.

ACIS, in *Mythology*, the son of Faunus and the nymph Simaethis, was a beautiful shepherd of Sicily, and beloved by Galatea. Polyphemus, one of the giants of Ætna, stung with jealousy and resentment, seized him, and dashed out his brains against a rock, after which he was changed into a river, which took his name; but, according to the Sicilian authors, Acis was a king of this part of the island, and was slain by Polyphemus, from a similar motive.

ACIS, a river of Sicily, greatly celebrated by the poets, which issues from a cold spring at the foot of mount Ætna. Its waters, which were held sacred by the Sicilian shepherds, and were famous for their sweetness and salubrity, are now impregnated with sulphureous vapours. The modern name of this river is Aci or Jaci.

ACOEMETÆ, the name of a religious sect which arose in the fifth century, and is expressive of their practice of keeping up constant worship in their churches; the rule of which is derived from the apostolic precept,—*pray without ceasing*. To observe the literal import of this precept, the establishment was divided into three parties, one of which was always occupied in religious duties, so that the church service suffered no interruption.

ACONITUM, ACONITE, wolfsbane, or monkshood, a genus of plants belonging to the Polyandria class. Winter aconite is a species of the genus Helleborus.

ACORUS, sweet flag, or sweet-smelling rush, a genus of plants belonging to the Hexandria class; one of the species of which is sometimes employed in medicine.

ACORN, the fruit of the oak-tree; in some countries, during scarcity, is employed as food, while in others, such is the diversity or caprice of taste and fashion, it is introduced at table, and considered a delicate part of the desert.

ACOSTA, URIEL, a learned Portuguese, the history of whose life presents a singular picture of wavering principles and versatile opinions, and affords a useful lesson of the fatal consequences of unsteady conduct. Acosta was born at Oporto, about the end of the sixteenth century. His father was descended from a Jewish family, but had embraced the Roman Catholic faith, in which also the son was educated. He received a liberal education, made considerable progress in science, and at last devoted himself to the study of law. At an early age he had accustomed himself to look on the dark side of things, and at last gloomy forebodings of futurity seemed entirely to take possession of his soul. Still, however, in the midst of religious doubts and mental perplexities, he continued his professional studies, and was appointed, in his twenty-fifth year, treasurer in a collegiate church. But the more he examined the religious system in which he was educated, the more he was dissatisfied with its peculiar tenets, and the more he dreaded the eternal fate of his soul. As his family were of Jewish extraction, it seems probable that he was not altogether free from some remains of the old leaven; but, whatever influence this might have on the change which he contemplated, he began to study Moses and the prophets; the consequence of which was, a determination to become a convert to the Jewish religion. The vigilance and zeal of those who superintend the propagation and establishment of the Roman Catholic faith, did not permit him to make a public avowal of such a change in the country where he now resided. Resolved to surmount every difficulty that opposed the accomplishment of his purpose, he resigned his office; accompanied by his mother and brothers he removed to Holland; and having submitted to the requisite ceremonies of the Jewish law, they were all admitted members of the synagogue of Amsterdam. Gabriel, his former name, was exchanged for that of Uriel. But this change in his religious belief had not the desired effect in quieting the unsettled state of his mind; new scruples arose, and new doubts, which it could not solve, presented themselves in rapid succession. He was little guided by prudence in expressing his opinion on those points on which his mind was not satisfied; and even had no hesitation in using violent invectives against those who supported the peculiar tenets which he did not approve. Sentence of excommunication was pronounced against him: and it was executed with such vigilance and severity, that even his own brothers were prohibited from addressing him in the streets. He published a book in his own justification; soon after which, a treatise on the immortality of the soul, in which Acosta was reviled as an atheist, appeared. This produced an answer, in which he attempted to confute that doctrine. Popular clamour was now excited against him; he was insulted in the streets; and he was not safe in his house, from the violence of the multitude. The irritated Jews applied to the civil power, and declared him the enemy of all religion. He was thrown into prison, subjected to a heavy pecuniary penalty, and all the copies of his works were seized and destroyed. After this severe persecution, and fifteen years exclusion from the Jewish church, he subscribed a formal recantation of his errors, and was again admitted into its bosom. But a few days only had elapsed after this event, when he was charged by his nephew with want of conformity to the laws of the synagogue in meats and drinks. He was again excommunicated. Having passed seven years more of his life, in some measure as an outcast from society, and being encouraged to hope for some remission of the severity of the discipline required, he declared his willingness to submit to the sentence of the synagogue. But he was deceived; the most rigorous penance was enforced; he was subjected to the ignominious punishment of receiving thirty-nine stripes; and he was laid on his back at the door of the synagogue, that every one might pass over him. Unrelenting persecution made Acosta desperate; he resolved on self-destruction, which he afterwards perpetrated; but he previously attempted to destroy his principal enemy, by shooting him with a pistol as he passed his house. This attempt failed. He instantly shut the door, and having another pistol in readiness, shot himself. This event happened at Amsterdam, about the year 1645. A posthumous work of Acosta, entitled "*Exemplar humanæ vitæ*," or a specimen of human life, which is supposed to have been written a short time before his death, was published by Limborch, with a refutation and criticism annexed. The strange character which Acosta exhibited, his love of controversy, and his vacillating temper in matters of religion, may perhaps be partly ascribed to the intolerant spirit of the times, but chiefly, it would appear, to a certain degree of alienation of mind.

ACOUSTICS.

Acoustics, a term derived from the Greek word to hear, is used to denote that science which treats of the nature, properties, and laws of sound. It has been divided, like the kindred science of Optics, into Diacoustics and Catacoustics—the former, respecting those sounds which come directly from the sounding body to the ear; and the latter, those which are reflected from other bodies before they reach that organ. The distinction, though undoubtedly just, obviously involves a theory, and is perhaps improper, therefore, in the commencement of an elementary treatise, more especially when the science itself is in a state of infancy. The correct division of any science must necessarily follow the acquisition of a knowledge of the materials composing it, a proper enumeration of the most important facts, and a cautious induction of general laws from them.

Sound, to use the language of Dr Johnson, is that which is perceived by the ear. This, indeed, is scarcely a logical definition, properly so called; but it sufficiently implies, though it does not express, what is meant by the word, in the judgment of all who have the faculty of hearing. It must be allowed, too, the merit of accuracy, as well in restriction as in comprehension. The ear perceives nothing but sound, and is the only organ which does perceive it.

The first part of this assertion requires no other proof, than an appeal to every man's experience. A seeming objection to the latter clause, arising from the circumstance of certain sounds being perceived when the bodies producing them are applied to the forehead, teeth, &c., although the ears be stopped, will be found, on inquiry, to have no real weight. In all of these cases, the organ of hearing is operated on through the medium of bones, membranes, cavities, &c.; for it is not essential to the perception of sound, that the external ear be affected, though this is materially conducive to its perfect discriminating power. The case of Mitchell, a boy born blind and deaf, whose history has been given by Mr Dugald Stewart, in a paper read before the Royal Society of Edinburgh, does not suggest any thing against this explanation. The disposition he has shewn, since infancy, to ring or strike objects against his teeth, may be accounted for on two principles, quite consistent with it. Either the nerves of hearing are not entirely wanting or useless in his case, so that he acquires some information by them,—or his teeth, by a process little or not at all attended to by others, furnish him with sensations, by means of which he perceives the relative hardness, or some other properties of bodies. This latter is probably the more correct conclusion, and might be amply supported by analogies drawn from the histories of many other individuals, who have been deficient in an organ of sense.

The ear alone, then, perceives sounds, and nothing but sounds. These are very various, and, either by the constitution of our nature, or the result of experience founded on it, communicate to us very different sensations, emotions, and information. They are signs, in fact, by which we learn to distinguish a multiplicity of objects, and that in so accurate a manner, that, to take one example for many, we can recognise a friend by his voice, without any intimation to our other senses, amongst a vast number of persons, all using the same language and speaking in the same tone. The power of which this organ may become possessed, in marking differences, as in the case of the blind, who are led, of necessity, to cultivate it, is scarcely conceivable by those who confine themselves to its more common attainments, and make up the deficiency by the other senses. How far its structure is accommodated to the purposes for which it is manifestly designed, and the manner in which it is affected by the variety in the tones and strength of the sounds it is subjected to, fall to be discussed elsewhere. The business of this article is quite distinct; and it is sufficiently important, not to require the interest of anatomical demonstrations, or the disquisitions of physiology, as an incitement to attention. We shall remark, however, as necessary to guard some readers against one bane of true philosophy and just logic, the drawing general conclusions from particular premises, that the ear differs so considerably in different orders of animals, that it is extremely difficult, if not impossible, to say what parts of its mechanism are essential to the faculty of hearing in general, or to what peculiar purposes the specific modifications of individuals are subservient.

Phenomena of Sound.—However constructed, it is certain the ear is requisite for the perception of sound. Let us now inquire what it is that produces sound, or, to speak more cautiously, what are the occasions on which the phenomena of sound take place? The investigation may be conducted in the following manner. A rumbling kind of noise attracts our attention: We remember to have heard something like it, when a cart passed over the street. We infer this to be the case at present, and we are not mistaken. Another sound is heard, similar to what we have often perceived when a certain rope was pulled in an adjoining room, and that rope, we know, is connected with a bell, which is made to ring on such occasions. Presently a confused noise occurs, for which we can assign no precise reason: But we refer it, by a rapid process of reasoning on past experience, to the fall of a heavy body on the floor above us. The conclusion is perfectly correct. Now follows an agreeable succession of soft and delicate sounds, which we ascribe, with equal confidence and truth, to a musical instrument called a hand-organ, that is played on by a man at a short distance from us. Immediately a beggar boy solicits charity in a whining tone of voice; and, on observing him, we remark his lips to be moving. In all of these cases, and in a vast variety of others, we discover, that the bodies from which the sounds appear to proceed, have been subjected to some kind of motion. Hence, after multiplying our observations, and finding no exception, we come to the conclusion, that motion is essential to the production of sound, or, at least, that there is a constant conjunction between sound and some sort or degree of motion in the body whence it proceeds. All bodies, we soon remark, do not give out sound with equal ease. Their nature, shape, and situation, appear to have some influence, both on the comparative facility and the kind of sound. The metals, especially, if in certain degrees of thinness, in certain shapes and magnitudes, are remarkably sonorous; glass, china, and stone-ware, have the same property. Other substances, and even the same substances in different states, or placed in peculiar circumstances, are made to sound with much greater difficulty, and the sounds which proceed from them are of shorter duration. We have instances of this kind, in earth, sand, most masses of stone, woollen, and other cloths, &c. Even the sonorous bodies before mentioned, when filled with these substances, or caused to press closely and for a considerable portion of their magnitude upon them, are rendered less fit for the production of sound than they were before. A few observations, and some familiar experiments soon point out some of the conditions on which these differences depend, or with which, at least, they are invariably united.

Having ascertained that sound is always connected with motion, it seems reasonable to enquire, what is the sort of motion most favourable for its production, or that is constantly associated with it. Let us, therefore, examine the states of those bodies which are remarkable for the freedom and duration of their sounds, at such times as they are producing them. We have a singular example immediately before us, that promises a little aid in our research. A long knife, spatula, or paper-folder, being pressed on the table by the fingers of one hand placed within an inch or two of the point, and in such a manner that the remainder of the blade may project beyond the edge of the table, immediately gives out a very peculiar and somewhat musical sound, as soon as the handle is pushed downwards by the other hand, and then allowed to spring up to its former position. During the continuance of the sound, and as often as it is produced, the fingers, by which the blade is still pressed on the table, experience a tremulous motion. We discover also, that as we either apply more fingers to the blade or remove some of them from it, vary the force by which we press it on the table, diminish or increase the quantity of the blade thus pressed, &c. we alter both the sounds produced and the tremulous motions accompanying them. This simple instrument, in short, may be so managed, and has been so managed, as to produce several notes, and to emulate, if not excel, most of the music of savages. Again, if a thin but large plate of copper or iron be struck in such a manner as to yield a durable sound, we shall easily perceive, by a finger gently applied to it, that it undergoes a very similar action. This may even be discovered by the eye, if some light substance, such as sand or dust, be strewed over its surface. When a glass vessel, partly filled with water, is made to sound by a wet finger passing artfully round the brim, as in the case of the musical glasses, we may distinctly observe an undulating or trembling appearance of the surface of the water, always when the sound takes place; and this motion, it cannot be doubted, is communicated to it by the glass, to which alone the moving force is originally applied. Minnows confined in the vessel, as we have sometimes noticed, appear to be sensible either of the sound or the motion thus produced. The atmospherical air contained in sonorous bodies of a particular shape, may be put into some corresponding motion by the same or different means. Thus, when a large bell is rung, or caused to sound by a blow, a person near enough to its mouth is quite sensible of a peculiar agitation of the air around him; and in some cases, as of bells of an enormous size, the vibrations of the atmosphere are so great as to prove very unpleasant. When a gong, or any such instrument, is sounded, the hand applied to the opening, even at some distance from the edges, is sensible of a tremor being communicated to it. In all such cases, and a thousand might be mentioned, it is most manifest, that the motion with which sound is, somehow or other, connected, is of a tremulous or vibratory nature, and that it is not confined to the body from which the sound seems to proceed, but is propagated to the contained fluid and ambient atmosphere.

That the nature of the body put into this sort of motion is comparatively of little consequence as to the production of sound, is proved by the fact, that every substance capable of being brought into a state of tension or elasticity, so as to admit of vibrations, is capable also of giving out sound. The nature of the substance must, of course, be considered so far, as that the proper condition for its vibrations may be effected, as this varies in different substances; but further it is unimportant in the general phenomena now considered. Metals, and other hard substances, must be in the state of thin pieces, or of hollow shapes, or in certain situations. Soft and very flexible substances, on the other hand, require to be stretched, or drawn tight. Hair, silk, catgut, strings of various materials, metallic wires, &c. when thus treated, become sonorous in so remarkable a degree as to be peculiarly adapted, and to be commonly employed, for musical instruments. The last class of substances we have mentioned, deserves still greater attention, as affording an excellent illustration of the conclusion we have already arrived at, as to the connection between sound and vibration, and as giving some curious information with regard to the modifying effect of changes in the latter, on the kinds and duration of the former. The examination of the action and musical product of strings, in fact, has brought Acoustics within the range of mathematical reasoning, and raised it, in consequence, to a place among the accurate sciences. It has not proved ungrateful for the elevation;—but, on the contrary, by suggesting some improvements and facilities in calculation, has afforded another example of that mutual subserviency of interests, by which the progress of the sciences has been so rapidly accelerated in modern times.

We shall now advert to the most important facts respecting this branch of our subject, and state, with as much simplicity as possible, what are the conclusions to which they lead. First, however, it is necessary to apprise the reader, that sounds are said to have strength and tone, and that these words mean very different qualities. To the first we apply the epithets, loud, soft, forcible, gentle, &c.; the latter we denominate high or low, sharp or flat, acute or grave, &c.; and by a little attention to the application of these terms, the qualities themselves will be better understood than by any definition we could assign. The distinction is of some importance. Lord Bacon seems to allude to it when he says, "The strength of a voice or sound makes a difference in the loudness or softness, but not in the tone." Tone, pitch, key, are often used synonymously.

Fundamental tone.—If a string that is stretched between two points, or that is suspended from a peg, having a weight attached to the lower end, be drawn a little out of the perpendicular line, and then let go so that it may return to its former position, it will be observed to vibrate several times on both sides of that position. During its vibration it also emits sound, varying in strength from greater to less as the vibrations become fainter, and at last totally ceasing together with the vibrations. If all circumstances remain the same, the sound thus produced has always the same tone, though it differ much in point of strength. This is generally denominated the *fundamental sound or tone* of the string. All strings have not the same fundamental tone; and, even the same string varied, as we shall immediately specify, is capable of giving out very different tones. Thus, if it be made longer or shorter, thicker or smaller, or be stretched by a greater or less weight or force, its sound will be altered. Universally, changes in any of these three circumstances, the length, weight, and tension of the string, are accompanied with corresponding changes in the sounds produced. What these changes are, may be briefly stated. If we diminish the length, we heighten the tone, that is, make it sharper. The same effect is caused by reducing the weight of the string, or by increasing the force that distends it. On the contrary, lengthening the string, increasing its weight, and diminishing its tension, make the tone deeper, *i. e.* more grave. Obviously, therefore, a difference in any two of these circumstances, may be compensated for by a variation of the third, provided we are acquainted with the exact proportions in which they are related to each other; and hence we can cause several strings either to give out the same notes, or to sound very different ones. On this fact is founded the construction of most of the stringed instruments used in music.

Now, the only particular in which these three modifying circumstances are found to agree, or, in other words, the only thing common to them all, is the power of varying the time in which a vibration of the string takes place. This is a most important observation, as it subjects the vibrations of musical strings to a calculation similar to that used in the case of pendulums, and of course gives rise to certain rules, or formulæ, which are of great utility in the practice of Acoustics. In alluding to these, which it is necessary we should do, we shall study to avoid mathematical intricacies either in substance or form, as our object is not to appear learned, but to be extensively useful; for which purpose, to be readily comprehended, is an essential condition.

The motion of any part of a string, from a point where it has been drawn out of its original or quiescent position, to a corresponding point on the opposite side of that position, is called a single vibration; so also is the motion from this last point to the former one, or the return. Both together, that is, the motion of the string from its point of inflection to its return to it, after having reached a corresponding point on the opposite side of the plane of inflection, constitute what is denominated a double vibration. Perhaps the terms semivibration and vibration, would be more appropriate, as there does not appear to be good reason for varying from the language applied to the parallel case of pendulums. We shall not, however, contend for words, and therefore abide by the current expressions.

Harmonical curve.—Now, it is found, that the times of the vibrations of a string are always the same, whatever may be the distances to which it is inflected from its quiescent or initial position. The times, in other words, are independent of the distances, a string always accomplishing its vibrations in equal portions of time, whatever may be the amount of its departures on either side of its original position. The velocity, therefore, must be different, being greater in the larger distances and less in the smaller; and this may be made obvious to the eye, in the case of a string continuing for some time to sound the same tone, but becoming gradually fainter as its vibrations occupy less space. The tone is dependent, as we have said, on the time of the vibration. Whilst the vibration, therefore, is performed in the same time, the tone is the same; and *vice versa*, if the tone be the same, the vibrations are effected in the same time. These two things are inseparably connected. The distance, therefore, or space through which the string vibrates, like the weight of a pendulum, does not form an element in any mathematical expression of the time of the vibrations, which, accordingly, is stated in terms of the length of the string, its weight, its tension, and the velocity which a body acquires in falling, for a second of time, by the action of gravity. If we substitute letters or numbers, therefore, in place of these terms, we may obtain certain algebraical or arithmetical equations, constituting the problem of the musical chord, which agrees exactly with the results of experiments on strings whose vibrations admit of being numbered. The problem was first resolved, in an intricate manner certainly, by our countryman, Dr Brook Taylor, and afterwards more simply by the illustrious D'Alembert. The particular curve which a string must form in order that all its vibrations be isochronous, or performed in the same time, has been called, from the former gentleman, who ascertained it, the *Taylorean curve*, and sometimes, from its properties, the *Harmonical curve*. A knowledge of its nature unfolds all the intricacies of vibrating strings and aerial pulsations, and is consequently the very basis of musical science. We shall content ourselves at present with a few deductions from the formula above alluded to. If two strings have the same length and weight, their times of vibration will be inversely as the square roots of the forces stretching them; and the number or frequency of their vibrations will be directly as these square roots. If the length and tension be the same, the number of the vibrations will be inversely as the square roots of the weights of equal lengths of the strings. If the weight of equal portions and the tension be the same, the frequency will be inversely as the lengths. We can tell, therefore, the number of vibrations which a string will make in a second of time; and, as the tones are dependent on the times, we can determine them also, and compare them together, on mathematical principles.

Comparison of Sounds.—Having ascertained so much with respect to musical strings, we are obviously in possession of a measure to which we can refer the tones of other sonorous bodies; for the sound of any body can be compared with that of a string of known length, weight, and tension. On adjusting the latter to the former, so that the two may be in unison, we conclude, on the general principles now established, that the number of vibrations performed in a given time is equal in both cases. A well practised ear is quite competent to this adjustment in all cases; and occasionally some phenomena occur, of a very striking nature, to point it out, even to those persons who cannot boast of such an acquisition. We mean the consentaneous vibration and corresponding tone of two or more bodies in unison, if near to each other, when only one of them is touched so as to sound. For example, we have observed the human voice, when raised to a certain tone, to be accompanied by the sounding of a guitar-string that happened to be in unison with it. A drum, when beat on, will occasion the vibration of another drum at a distance, as may be seen by the motion of dust or sand put on it. The deep tones of an organ not unfrequently produce vibrations in the wooden forms used in church-pews. There are many other instances of the same sort. May not the inclination, sometimes scarcely resistable, which persons of a musical talent and voice feel to join in a concert, depend, in great degree, on some involuntary principle of a kindred nature?

The analogy between the vibrations of strings, and those of other sonorous bodies, is obviously greatest when the latter are brought into a state of tenuity and elasticity, so as most to correspond with the former. We have already specified wire. To this may be added rods, rings, cylinders, and thin plates of metal, membranes of any kind when drawn tight, in short, all bodies which can be brought into a state admitting vibrations, as strings do, on both sides of a fixed axis. Other bodies, however, nay, even the same bodies, by particular management, may be made to vibrate in a different way; viz. longitudinally, or from end to end; and some bodies, perhaps, scarcely ever vibrate in any other manner.

Here a new field of inquiry opens upon us. We can scarcely imagine, that the same laws which we have hitherto contemplated, will apply to circumstances apparently so widely different. The densities and elasticities of the bodies, not to mention the modes in which they may happen to be fixed during our examination, may reasonably be expected to require consideration, and, of course, to modify the formula used to denote the vibrations. Additional difficulties present themselves; and this part of Acoustics, in consequence of the comparatively recent and limited attention bestowed on it, is still very imperfectly understood. A few general observations are all we shall hazard on the subject.

Modifications of Sound.—The circumstances affecting the pitch or tone of bodies vibrating longitudinally, independent of the mode in which they are fixed, are conceived to be four; viz. their length, their specific gravity, their elasticity, and the rate at which this last quality is varied, by compression and expansion. The three first are principally concerned in the case of solid bodies, though not excluded from those of fluid and aerial bodies, to which, again, the last mentioned circumstance has almost an exclusive reference.

These modifying causes, it will readily be understood, do not all equally affect the tones of bodies. Generally, the tone is made acute by an increase of the elasticity of the sonorous body; and the diminution of the length and specific gravity has the same effect. The precise proportions are not easily determined; but it has been remarked, that a diminution of the length to one-half, of the specific gravity to one-fourth, and augmenting the elasticity four times, have nearly corresponding power. The length is commonly much easier varied than either of the other circumstances, and is more usually had recourse to. An increase of elasticity, indeed, is readily enough accomplished by an elevation of temperature. But this is confined to narrow limits, and cannot be used in general as a source of permanently heightened tone, at least to a great degree. We may see the effect of increased temperature to raise the tone, in the case of such instruments as the flute, hautbois, &c. When long played on, or held to the fire, they give out much sharper sounds, to the great vexation of violin performers, who frequently break their strings in attempting, by additional tension, to preserve the unison. The tightening of tambourines, drums, battle-doors, &c. by the application of heat, on the same principles, raises their tones.

As the different elastic fluids operated on in some of Mr Dalton's experiments were found to expand, and to suffer contraction, with the same increase or diminution of temperature, it is evident, that the last of the four circumstances enumerated may be assumed as equal, in the case of different bodies of this sort, at the same temperatures. These bodies, therefore, may be considered as differing in density only. The difference of temperature, however, is clearly an element in any expressions used to denote the relation subsisting between the same or different elastic fluids. Hitherto, we may notice, the utmost obscurity pervades this part of Acoustics, which, at best, perhaps, can only be considered as simply curious. That many singular, and, probably important facts, remain to be disclosed, however, may be confidently believed. Experience teaches us to be cautious in setting limits to discovery; and accident often reveals what no wisdom or science on the part of man could have possibly anticipated. A very striking fact, noticed, we believe, by Dr Higgins, may probably lead to results of no ordinary import. We allude to the peculiar sound occasioned by the combustion of a small stream of hydrogen gas, when surrounded by a glass or porcelain tube. This, as far as we know, has neither been satisfactorily explained, nor followed up by suitable experiments on other elastic fluids. The tones of bodies vibrating longitudinally, are ascertained to be more acute than those of the same bodies when vibrating laterally. We infer, therefore, that their vibrations are quicker in the former case, and, as they are not so loud, that they occupy less space. But it is, perhaps, impossible to determine the number of vibrations in these cases, especially in solids. Some conclusions have been ascertained, of a very general, but still a very useful nature. Two or three may be specified.

If any given body be either fixed or free at both extremities, the number of longitudinal vibrations performed by it in a second of time, will be the same; and consequently, on the general principle, the tone will also be the same. If it be free at one end, and fixed at the other, we must reduce its length one-half, in order to make it give out the same tone. The case of elastic fluids is similar, and hence, we establish a very important analogy between aerial pulsations and the longitudinal vibrations of solid bodies. It would perplex most readers, perhaps, to pursue the comparison throughout, and to apply the modifications which the different natures of the two classes of bodies require. Nor is it necessary to enter upon it for any practical purposes. We shall merely mention, therefore, that the column of air in a tube or wind instrument is to be considered as the sonorous body, and that its vibrations are occasioned by the alternation of condensed and rarified particles or layers throughout its length, whilst the whole is moved longitudinally by the original impelling cause. The fact noticed by Dr Higgins, to which we have already alluded, may be conceived to confirm this solution, and to be itself, in turn, explained by it.

Harmonics.—Thus far of the fundamental tone or sound of bodies, as connected with their vibrations, whether laterally or longitudinally. An additional fact, curious in itself, and presenting difficulties of a peculiar nature, leads us to the consideration of what have been termed *harmonics*. The fundamental tone is not the only sound given out by a musical string. On the contrary, this expression is used to discriminate it from other sounds, with which it is often, and, in some cases, invariably associated. To these additional sounds, from the circumstance of their concurrence with the fundamental note in the production of an agreeable effect on the ear, the term harmonics has been applied. Every ear, it ought to be remarked, cannot distinguish them. But a little attention will generally enable a person to obtain this power, particularly as to what are called the twelfth and seventeenth, the octave usually coalescing with the fundamental note, so as only to be discovered by a well practised observer, whereas the other two, which arise later, are easily enough detected. If the harmonic notes be very acute, they will not easily be recognised, as the ear is not familiar with their range of tone; on the other hand, where the fundamental note is extremely grave, it is apt to escape being noticed in the harmonics associated with it. The reason plainly is, that the ear, though it may be accommodated to a vast variety of tones, is commonly much more acquainted with those which are intermediate between the very high and the very low, and is consequently better able to compare them together.

We can scarcely imagine that these harmonics are dependent on any thing else than the principle to which, after a most unexceptionable induction, we refer the production of the fundamental tones. Nature, we may be allowed to say, is sparing in causes, and fruitful in effects, contrary to the puny wisdom and limited agency of man, who has to multiply his instruments, and vary his plans, in order to accomplish a small variety of purposes. On this presumption, then, we might even, *a priori*, decide, that these harmonics are regulated by the general laws of vibrations, which we have ascertained to exist in every case of the original or parent sound; that they are, in short, modifications of the greater vibrations of the strings. Experiment fully warrants this conclusion; and, accordingly, it may now be held as an authentic part of the science. The observations of Professor Robison, Dr Thomas Young, and others, put it beyond doubt, that besides the vibration of the whole string, on which the fundamental note depends, there take place several vibrations of parts of the string, either in the same or in different planes, and that these are the source of the fainter, but acute sounds, which we are now considering. Still it must be allowed, the subject has not received that elucidation which its curiosity, at least, would prompt one to desire. In concluding it, we shall briefly observe, that strings are not the only sonorous bodies which are capable of producing harmonics; for those bodies which vibrate longitudinally, and also wind instruments, have been discovered to yield such sounds. The experiments of Dr Chladni on the former, have afforded no slight confirmation of the views above stated, as to the connection of harmonics with subsidiary vibrations of the sonorous bodies. The secondary sounds of wind instruments may be traced to similar minute vibrations of the columns of air, from whose greater movements the fundamental sounds derive their origin. This last remark leads us to regard the atmospherical air as itself capable of vibrating, and, consequently, of giving out sound; and we may enquire, whether other fluids, elastic or nonelastic, may not produce similar effects? The subject has been partly anticipated already, but demands additional remarks.

The proposition, that all fluids, whether elastic or nonelastic, may be made to vibrate and to become instrumental in the production of sound, seems the just inference, from most extensive observation. We shall not specify particular examples. It is of more consequence, perhaps, to remark, that this proposition is, in fact, but part of a general conclusion, which every reader will be prepared to admit, on the ground of his own experience, in addition to what has been said, viz. that all bodies, by proper management, are capable of giving out sound; and that, in producing this effect, they suffer vibrations. Farther, it is an obvious deduction from this, in conjunction with a well known fact, that sound requires time to be propagated from one place to another, that the vibrations of the sounding body are first communicated to the adjoining portion of the ambient medium, thence to another portion, and so on successively, till it reach the ear of the observer. The impression there made, it will, at once, be conceived, excites the sensation of sound, and, according to its force, and kind, and frequency, occasions that variety of sensation which is so important in our intercourse with the external world. That the same medium between the sounding body and the ear is requisite for the production of this sensation, appears from the fact, that the sound of a bell, placed in the receiver of an air pump, becomes gradually more and more faint as the air is withdrawn, and, at last, is scarcely audible; it would, no doubt, be completely lost, if a perfect vacuum could be formed; and, on the admission of the air, the sound of the bell again becomes distinct.

That water conducts sound, is easily shewn, and must be known to most persons. Professor Robison made a decisive experiment on the subject. He immersed his head under water, at the distance of 1200 feet from a bell made to ring in the same medium. The sound of it reached him. Divers, a few feet under water, hear what is said to them. The sound occasioned by a stone struck forcibly on the bottom of a river or pond, can be perceived. The gurgling of rivulets, &c. may be referred to the same principle. A calm sea is known to convey sound to an immense distance. Thus, whales can frequently discover the boats that go in pursuit of them; and, accordingly, a breeze producing a ruffled sea, is preferred by the Greenland fishermen. *Lastly*, we may notice, that fishes are provided with organs of hearing, which would be useless if water did not convey sound; and they may, in fact, be easily perceived, at times, to be affected by it.

Certain solid bodies, it is well known, propagate sound with great rapidity, and that, apparently, without the medium of the air or any other fluid; and, universally, those solids answer the purpose best, which are most adapted to transmit impulses or vibrations. Metals are peculiarly fitted for it, but not all in the same degree; and, to these, may be added glass and wood, and many other substances. The experiment, as far as we know, has not been performed; but it cannot be doubted, that if the end of a rod were placed so as to be struck or scratched when under an exhausted receiver, it would vibrate, and consequently communicate sound at the other end, out of the receiver, as readily as in the open air. This experiment, and a similar one in the case of a condenser, both of which, we think, might easily be contrived, would go far, perhaps, to determine whether or not the tone or pitch of sonorous bodies continued unchanged in different degrees of density of the inclosed fluid.

Velocity of Sound.—The velocity of sound, as may easily be collected, from what we have already mentioned, is different in different media. The genius of Newton subjected it to calculation, at least in the most important case, that of the atmospherical air. His reasoning was not altogether unexceptionable, and his conclusion made the velocity less than what experiment proved it to be. On the whole, however, his principles have been confirmed; and a suggestion of La Place has pointed out a reason for the difference of results, founded on a chemical principle of known and very extensive agency, viz. the effect of the condensation of the aerial particles concerned in vibration, in giving out heat, and so increasing elasticity, or diminishing density. Newton's calculation brought out the velocity at 1057 feet *per* second. The experiments of Dr Halley determined it to be 1142; those of the Florentine academicians, 1148; of the French, 1109; Bianconi, so low as 903; Walker, so high, at one time, as 1526; and of others, very variously. The mean has been taken at 1130; and this tolerably well corresponds with La Place's suggestion in favour of Newton's hypothesis. Whatever estimate we take, it seems certain, that the velocity of sound through air, is the same as that of an impulse; and hence a confirmation of the opinion, so often stated, that sound and vibration are intimately connected. If additional support were needed, we have it afforded in the case of every substance through which we can trace the velocity of both. This, indeed, is so great, in general, and more particularly in the case of solids, that it is perhaps impossible to compare any of them together in this respect. One thing, however, is clearly to be ascertained, that the sound and the impulse are transmitted, *i. e.* proceed with equal or the very same velocity. On the whole, then, it seems absolutely impossible to hesitate for a moment, in admitting the general inference to which all the facts we have enumerated point, and with which every reasoning we have thought ourselves justified in making on them concurs, that sonorous bodies communicate their vibrations to the adjoining medium, and that these, being conveyed to the ear, occasion the sensation of sound. But here we pause, and abandon all attempts at explanation. How these things are brought to pass, we cannot say. The speculation, we conceive, is utterly fruitless, and we are little disposed to indulge in conjecture. We must confess our ignorance; for we really cannot tell, why impulse produces vibration, not colour; or what is the reason, that vibrations, communicated to the ear, are followed by the sensation of sound, and not by that of taste. We have reason to be contented with the constitution that the Creator has given us, and its adaptation to the circumstances in which we are placed. But we should think it presumptuous in this, or any other case, to say to Him, "Why hast thou made us thus?" or, "Why is the world thus formed?" though it be our employment to investigate his works, and our happiness to discover their perfection.

Practice of Acoustics.—The practice of Acoustics is plainly deducible from the ascertained laws of the vibrations of sonorous bodies, and the reflection of sound. To the former, might properly enough be referred Music, which may be considered as, in fact, a part of Acoustics. Its importance, however, and its magnitude, in conjunction with certain circumstances, dependent, apparently, on peculiar principles in the human mind, have occasioned it, and perhaps advantageously, to be always treated of in a separate treatise, to which we refer. But a few remarks fall in with the present subject. The sounds employed as the elementary parts of this delightful art, are the product of different sources, in all of which, however, vibration appears to be the proximate cause. The tension of strings, the elasticity of solid bodies, that property of the air by which it is rendered susceptible of vibrations, and the conjunction of two or all of these agents, furnish us with all the variety of notes, which, when succeeding each other, according to certain rules, constitute melody, or, when associated together, and similarly arranged, form the still more powerful and nicer branch of the musical art, denominated harmony. Tension may be held as the chief agent in many of the stringed instruments; as, the harp, guitar, violin, piano-forte, &c. Though, even in these, to a certain degree, another agent is employed, the elasticity, and perhaps the reflecting power, of what is called the sounding board. We have other examples of tension as a musical power in the case of the drum and the tambourine.

Elasticity seems the only agent in the musical tones of the bell, harmonica, gong, stacada, musical glasses, &c. We have examples of simple wind instruments, in the flute, flageolet, syrinx, &c. and of mixed ones, in the clarionet, hautbois, trumpet, bugle, &c.

The same sonorous body, as we have already remarked, may produce a variety of sounds at one time. These are generally such as might result from the vibrations of aliquot parts of the body, but they are not the same in every individual substance. In chords and open pipes, the series of parts concerned in this effect may be represented by the natural numbers; in stopped pipes, by the odd numbers only; whilst, in the case of rods and bells, it is scarcely possible to discover any determinate proportion between the fundamental and secondary or harmonic sounds, and, therefore, between the entire and the partial vibrations which occasion them. It is singular, that, in the cry of the peacock, certainly far from being a musical bird, there are two notes, one grave, the other acute, and that the latter is the octave to the former. The braying of the ass appears to be an assemblage of a great many notes, concords and discords, uttered all at once. A selection from these, or the proper management of them in series, would undoubtedly be very agreeable. The animal, however, has not the art requisite for this effect. In the feathered tribes we have many examples of great musical power, and exquisite taste. The instrument, in all of them, is to be sought for in the muscles of the larynx, made elastic seemingly by an effort of the will, and caused to vibrate by the forcible ingress and egress of the air. These muscles, according to Mr John Hunter's observation, appear to be the strongest in the best singers. The nightingale has been particularly noticed in this respect; and this accounts for the great distance at which its notes can be heard, not less, it is said, than half a mile, in a calm evening. The science of this bird has been long celebrated. Mr Barrington was able to discover sixteen different beginnings and endings, in the compass of its song; and he remarked also, that the intermediate notes were varied in their succession with so much judgment, as to give a most pleasing effect. The warbling of many birds may be said to yield harmonic sounds, which differ in different species, and appear to be dependant on some conscious exertions of the songster. The shake of some of them may be remarked not to consist of the alternation of two contiguous notes, as is usual in instrumental music, but of notes separated by a wider distance, as thirds, fifths, &c. This is done so rapidly at times, as to have nearly the effect of chords. At other times, the notes thus connected do not naturally harmonize, and the effect is consequently disagreeable. Here we speak of human auditors only, as it is probable that both the performer and his kindred are highly gratified by the exercise.

It is when the sounds combined together are related to each other, in a manner so that the vibrations admit of a common period after some alternations, that we experience a pleasing concord. Where the proportions between the associated sounds are simplest, in general we have the greatest satisfaction. And yet the ratio of equality in the frequency of vibrations, which constitutes unison, is not particularly agreeable. A little greater difference even than the proportion of two to one, or the octave, as it is called, is requisite to high musical power. Thirds and fifths, when conjoined with the fundamental tone, produce the finest harmony. But this, when long continued, or frequently recurring, becomes wearisome, and hence the necessity, as composers and performers well know, of occasionally changing both the fundamental sounds, and the proportions of the associated ones. The judicious introduction of discords, on the same principle, and as giving a peculiar expression or character to a composition, must be allowed a high place in the excellencies of the modern science.

Æolian Harp.—There is one instrument which so strikingly illustrates and exemplifies what we have now said, and which is really of so pleasing and remarkable a nature, that we must be allowed to occupy a little room in its description. The reader will perceive, we allude to the Æolian harp or lyre. This instrument has been denominated Æolian after Æolus the god of the winds in the ancient heathen mythology, from the circumstance of its being played on by the impulse of a stream or current of wind, independent altogether of any voluntary performer. It consists simply of several catgut or wire strings stretched over a sounding board, and brought into unison by an equal but slight degree of tension. In this state, when exposed to a gentle breeze of air, as at a chink of a window, it yields the richest variety of sounds, in almost every possible association and series, according to the variable force by which it is made to vibrate. Several modifications of the structure of this instrument have been proposed and carried into effect, but, in all of them, it may be remarked, the same principle, of having the strings in unison, has not been retained. Now, as it has been distinctly proved, that a single string can yield every change of harmony, according to the mode in which its various parts are affected, it is obvious that a combination of strings, brought into unison, and caused to vibrate by the ever-varying influence of a current of air, will produce an almost infinite variety of sounds. The strings, however, rarely vibrate throughout their whole length, so as to yield the fundamental notes, but most commonly are occupied with some of the harmonics. As any part of a string by the peculiar manner in which the wind blows on it, may become, as it were, a whole, and so give out a fundamental note, which again has its own harmonics, arising from the vibrations of its aliquot parts, it is evident, that a source is opened, in this very simple instrument, of almost every variety of concord, and every wildness of discord that may be requisite for the most enchanting effects. Perhaps the only thing necessary to render the Æolian harp one of the finest musical instruments, is the expression of design, or the production of air, as it is called. But of this, it is probable, from the mode in which its powers are excited, it will ever remain destitute. The only method that seems likely to redeem it from this great deficiency, is, to subject it in some suitable modification of structure, to the pipes of an organ. We hint this without having any considerable expectation that the due attention to all the circumstances of the case will ever be bestowed to render it even subsidiary to the powers of that noble engine, far less to raise it to supreme rank among manageable agents of music.

Reflection of Sound.—The reflection of sound is, apparently, obedient to the laws which regulate that of light. In both cases, the fundamental proposition holds, that the angle of reflection is equal to the angle of incidence. On this principle, then, it is easy to explain some curious and well-known phenomena.

Echo.—An echo is simply the repetition of sounds occasioned by the reflection of vibrating portions of air. The bodies producing it may be either plane or curved; and the circumstance of roughness and smoothness of surface, seems little to modify the effect. Hence, walls, rocks, the sides of hills, groves of trees, &c. are found to answer the purpose, perhaps, equally well. As sound moves very rapidly, it is evident, that the reflecting surface must be at a certain distance, in order that a portion of time may elapse between the original sound and the reflection of it to the ear of the observer that admits of being appreciated. If the distance be under 50 feet, the two sounds come so closely after each other as to be confounded together, and, therefore, it is imagined there is no echo. A distance of about 90 feet from the reflecting surface is sufficient for a single echo, that is, for one that repeats a single syllable immediately after it has been pronounced. For an echo that may repeat a dissyllable, double this distance is required, &c. Compound echoes, or those which repeat the same sound several times, are occasioned by different reflecting surfaces, situated at proper distances. We have good examples of them when cannon are fired in the neighbourhood of woods, mountains, and the sea. The sound may be distinctly observed to recur at short intervals for several seconds. It is highly probable, that the clouds are reflecting bodies. Thus, the rolling of thunder seems to be a reverberation from them, aided by some of the other bodies already mentioned on the surface of the earth; and it is quite easy to understand, how a single electrical discharge may occasion all the noise we hear in one peal. The distance at which this discharge takes place, it may be worth noticing, is pretty readily ascertained, by reckoning the time between the flash of lightning and the first of the noise. About four and a half seconds, or, which is nearly equivalent, five pulsations of the artery at the wrist of a person in good health, may be allowed for the passage of sound over the space of one mile. The same remark is, of course, applicable to the case of discharges of fire-arms, &c.

The third or fourth repetition of a sound is not necessarily weaker than the preceding ones, but, on the contrary, is sometimes louder. This has been noticed, for example, in the echo at the lakes of Killarney in Ireland. It is observable also, in certain situations, when thunder or a cannon is heard. The reason is obvious. There are more reflecting surfaces in the wider sphere, than are sufficient to compensate, by returning pulsations, for the superiority of distance gone over.

Whispering Galleries.—Sounds striking on concave surfaces are reflected from them, and after reflection converge to points which are the foci of these surfaces. It follows, therefore, that the ear may be so placed in one, as that it shall hear a sound better than when situated nearer to the point of the first impulse: again, in the case of two concave surfaces placed opposite to each other, persons in their foci may carry on a discourse which shall be inaudible to others who are intermediate. The construction of whispering galleries is founded on this principle. It has been usually found, that buildings of an elliptical or octagonal form answer best for this purpose.

Speaking Trumpet, &c.—The operation of speaking and hearing trumpets has been attempted to be explained on the principle of the reflection of sound. But there is some difficulty in the application. In general, indeed, we may remark, too much stress has been laid on the analogy between the reflection of sound and of light. On the great scale, no doubt, the resemblance is very striking; but we shall probably err, if we conclude, that the laws of light are perfectly appropriate to every minute portion of sound. Many experiments, and some very nice observations, are needed, to ascertain the peculiar differences in the two cases, or to warrant us to explain any phenomenon of the one on the known principles of the other. If analogy alone were to govern us, why, we would ask, do we give the preference to light over sound? Ought we not to give fair play to both, and so explain the phenomena of the former by what we have discovered as to the vibrations, &c. connected with the latter? The thing is absurd. Analogy, then, may mislead us.

The speaking trumpet is intended to convey the sound of the voice in a particular direction, and to a greater distance than it can reach without such aid. A hollow cone, or cylinder, of almost any kind of substance, will answer; and seems to produce the effect, principally, by preventing the diffusion of the aerial particles, till they have been subjected to a greater impulse in one direction than they would sustain if unconfined. The hands, it is well known, can be applied to the mouth so as to accomplish this purpose to a certain degree. Sailors commonly have recourse to this natural auxiliary.

The hearing trumpet somewhat corresponds in form, &c. to the speaking trumpet. It has the effect of augmenting the intensity of sound, and is therefore employed by persons who hear imperfectly. The pulsations collected by it, at the larger opening, are conceived to be directed through the tube in a condensed form, so as to come upon the ear at the smaller end with a more forcible impulse. A good deal of the effect, however, ought to be ascribed to the circumstance of the ear being secured from the distracting influence of any lateral sounds. The hand applied hollow over the ear, with an opening in front, is found to assist the hearing, probably, on both principles, but more particularly the latter.

Invisible Girl.—What are called acoustic tubes, are merely pipes, usually made of metal, employed to convey sound to a distance. They are applicable to a variety of purposes; and when combined, as they may readily be, with reflecting surfaces, are capable of producing very amusing effects: The singular deception, called the invisible girl, which was exhibited some years ago, is of this sort, and excited no small degree of interest in the attempts to explain the nature and construction of the apparatus.

A short description will easily make it understood. A large hollow metallic ball, in which are inserted four trumpets, is suspended by ribbons or slender silken cords within a frame of wood; and between this

Acoustics. frame and the ball and trumpets, all connection seems to be cut off, excepting by means of the cords or ribbons. But in two of the upper rails of the frame, there is a small opening directly opposite to two of the trumpets. These openings are covered with a fringe, or concealed by any other contrivance, to prevent them from being observed; and they communicate with a tube which passes through the two horizontal rails, is continued through one of the upright rails of the frame, and under the floor of the apartment to an adjoining room. At the termination of this tube, the accomplice, generally a lady, sits, and applying her ear to the tube, hears what is said by any person speaking near any of the trumpets; and, as the reply comes in a weak and rather indistinct voice through the tube, and is reflected from the hollow ball, it seems to proceed from the ball itself; and in this consists the deception. To see what is passing in the room, an opening is made in the partition, and filled with glass, which also is carefully concealed.

Sound-Boards.—The sound-boards sometimes used in churches, &c. in order to aid the speaker's voice, are to be considered as operating entirely by the reflection of sound which they occasion. They are not found advantageous in theatres, as their distance from the speakers is necessarily too great to admit of their being sufficiently operated on by the voice. They are generally constructed of a thin broad piece of wood. But the best shape for them does not appear to have been accurately determined. The precise purpose for which they are intended, and the nature of the building in which they are to be erected, require particular consideration. The sound post of a violin, and some other instruments, is not only useful as a prop between their two sides, or back and front, but seems to have a musical effect, both as a reflecting surface, and as being susceptible of vibrations.

Acquapendente || Acre.

ACQUAPENDENTE, a town in Italy, which is situated on a mountain, derives its name from a fall of water in its vicinity, and is 57 miles north from Rome.

ACQUARIA, a small town in the district of Modena in Italy, is 12 miles south from the city of Modena, and celebrated for its mineral waters.

ACRA, or ACARA, in *Geography*, formerly a separate kingdom on the coast of Guinea in Africa. Before the French revolutionary war, the English and other powers had strong forts and factories on this coast, with each of which was connected a separate village. These villages or towns, it is said, are all known by the name of Acra. N. Lat. 5° 40′ W. Long. 0 14′.

ACRA, one of the hills of Jerusalem, supposed to derive its name from the fortress erected upon it by Antiochus.

ACRAGAS, in *Ancient Geography*, a town of Sicily, derives its name from its situation on a steep rock. This place was called Agrigentum by the Romans; and the inhabitants are represented as having magnificent houses, and being immersed in luxury.

ACRE, the ancient Ptolemais, a sea-port town of Syria, is situated on an extensive plain, which is surrounded by a ridge of mountains on the north and east; on the south by a semicircular bay extending to mount Carmel; and on the west by the Mediterranean. Acre is celebrated, both in ancient and modern history, as the scene of many splendid warlike deeds, and, consequently, has often changed masters. Ptolemy, from whom it derived its name, surrendered it to his mother Cleopatra. The Saracens were in possession of Acre at the beginning of the 12th century, and in the holy war they were driven from it by the Christians. Saladin, the sultan of Egypt, had obtained possession of it in 1187; and in 1191, it yielded to the united arms of the Christians, after a siege of three years, and the loss of 100,000 men. In the course of the succeeding century, Acre acknowledged various sovereigns; and when the Christians were driven from Jerusalem, it became their principal town in Syria, and constituted the general emporium of trade between the eastern and western parts of the world. But, in consequence of the excessive licentiousness which prevailed in the city, plunder and robbery became common in the surrounding country. To correct these abuses, the sultan Kahlil proceeded against Acre with a great army, and, after a siege of 33 days, took the town by storm, when 60,000 Christians were either massacred or reduced to slavery.

From the time of the expulsion of the Crusaders, Acre remained in a state of desolation till it was fortified in 1750, by Daher, an Arabian Scheik, who long maintained his independence against the Ottoman government, and was at last basely put to death by its emissaries, in the 86th year of his age. In 1799, Acre again became the scene of war. The French advanced to it in the spring of that year; and as the fortifications were in a ruinous state, and mounted with a few rusty iron cannon, some of which burst every time they were fired, the pacha, Djezzar, was about to abandon the place, when Sir Sidney Smith, with a squadron, anchored in the road of Caiffa. The British admiral encouraged the pacha to hold out, and sent an engineer to assist him in fortifying the town. Acre was invested by Bonaparte himself, but all his exertions were repulsed by the activity and bravery of the British; and at the end of 61 days, having suffered many severe losses, the French raised the siege. In 1759, Acre suffered considerably from an earthquake; and in the succeeding year, 5000 persons fell victims to the plague.

Acre is one of the chief towns on this coast; the houses are built of stone, with terraced roofs; the streets are very narrow; but some of the public edifices are distinguished by their grandeur and elegance. The mosque is described as one of the finest specimens of eastern architecture; the splendid fountain is reckoned superior to the celebrated buildings of a similar description in Damascus; and the Bazar, or covered market, is spacious and elegant. The heavy rains of winter produce accumulations of water, forming lakes in the vicinity of the town; and the exhalations in summer, render the air unwholesome. The soil is fertile, and, in some places, well cultivated.

The harbour of Acre is commodious and well sheltered. The chief part of the trade consists of corn and cotton, but it is entirely monopolized by the pacha. Acre is 24 miles S. from Tyre, and 45 N. from Jerusalem. N. Lat. 32. 40. E. Long. 39. 23.

ACRE, in its original signification, from the word *acher*, Saxon, or *aker*, German, a field, was applied to any open ground of no determinate extent; but it is now used as the universal measure of land in Britain. The English acre contains four square roods of 40 perches or poles each, and each perch of 16½ feet. The English acre includes 10 square chains, of 22 yards each, or 4840 square yards. The Scotch acre contains four square roods, each rood equal to 40 falls, and each fall equal to 36 square ells. The Scots acre is also divided into 10 square chains, and the chain is 24 ells in length, divided into 100 links. The English acre is about three roods and six falls of the standard measure of Scotland. The Irish acre is equal to one acre, two roods, and about 19¼ perches English.

ACRE-*fight*, an ancient form of duel, fought by the Scotch and English, with sword and lance, on the frontiers of the kingdoms. It also obtained the name of *camp-fight;* and hence the appellation of champions, because the combatants engaged in the open field.

ACRIDOPHAGI, or LOCUST-EATERS, as the Greek words of which it is formed import, an ancient people of Ethiopia, who lived on locusts, according to the exaggerated narrative of Diodorus Siculus, a credulous historian, who lived about half a century before the Christian era. The following description of the unfortunate locust-eaters of Ethiopia, is given by that author: "Their complexion was deep black; they were of small stature, and, in general, short lived; but they were, at the same time, extremely active. They had neither herds nor flocks, but depended entirely on locusts for their food. The close of their life was most miserable. Winged insects of different kinds were ingendered in their bodies, at first about the breast, and afterwards over the whole frame; and, while the insects forced their way through the skin, an intolerable itching, which terminated in the most excruciating pains, was produced; and, at last, the miserable sufferer expired, under the most severe agony, and uttering the most dreadful cries." The same author records, that this people collected immense quantities of locusts, and having abundance of salt in the country, they preserved them for future use. The marvellous part of this relation has undoubtedly arisen from the groundless belief, that the production of insects in the body was the necessary consequence of feeding on locusts.

The term, locust-eaters, which has been a copious subject of discussion, both in ancient and modern times, ought not to be limited to any particular nation or people; for, whether from inclination or necessity, no such people could possibly exist. Those countries which are subject to the calamitous visitations of the locust, furnish also the richest crops of grain and herbage; so that the ordinary animal and vegetable food, when it can be had, must be preferred to that of any of the tribes of insects. But, if the subsistence of any nation depended solely on the locust, it would, indeed, be most precarious; since, fortunately, in regions that suffer most from the ravages of that insect, intervals of several years happen, during which not one makes its appearance. In this period, therefore, the locust-eaters, having no other resource, must perish. But the difficulty admits of an easy solution, from the consideration, that the accounts of all authentic travellers agree in stating, that locusts are eaten chiefly in times of scarcity; and, in some parts of Africa and Arabia, they are sometimes sold in the public markets. The latest account of the use of locusts as food, is given by Mr Campbell, the missionary traveller in Southern Africa; who says, that the Bosjesmen or Bushmen, are supplied in summer with locusts, which they dry and pound into powder, to be used as a substitute for flour. The term *bark-eaters* would not be less appropriate to the poor Norwegians, who, in times of famine, use the bark of certain trees, either alone or mixed with a scanty portion of grain, than that of locust-eaters to the people inhabiting those countries which are visited by that destructive insect.

The passage of Scripture which narrates, that St John the Baptist *fed on locusts*, has been a frequent subject of discussion among commentators. While some have supposed, that the word, translated *locust*, signifies the tops of certain trees, others think that it refers to quails or some other birds. But the prevailing practice in eastern countries, in times of scarcity at least, removes the difficulty, and shews that the literal import of the words may be at once admitted. And perhaps the simple fare, and humble garb, of the forerunner of Christ, were meant to be expressive of the unobtrusive character of the dispensation of the Gospel.

ACROATIC, or ACROAMATIC, denoting something profound or abstruse, is the denomination of those instructions which Aristotle delivered to the favoured or more advanced disciples; and is used in opposition to *exoteric*, which was applied to his public lectures, which, it is probable, were of a more popular character.

ACROCERAUNIA, in *Ancient Geography*, a range of mountains which divide the Ionian from the Adriatic sea, so called from being often struck with lightning, and frequently referred to by classical writers. *Monti della Chimera*, is the modern name.

ACROPOLIS, in *Ancient Geography*, the citadel of Athens, and one of the divisions of that city, as its name imports, was built on an eminence, and had nine gates or entrances, the principal of which was by a magnificent flight of steps of white marble.

ACROSPIRE, an old term in *Vegetable Physiology*, denoting the shooting or germination of grain, is chiefly applied to the process of malting, and corresponds with *radicle* and *plumula*, which are more commonly employed.

ACROSTIC, derived from two Greek words, signifying *extreme* and *verse*, is a species of poetical composition, in which the first letters of the verses form the name of the person or place intended to be commemorated. But this artificial effort of the muse is rarely recognized, even in the humbler departments of modern poetry.

ACROSTICHUM, Fork-fern, Wall-rue, or Rusty-back, a genus of plants belonging to the class Cryptogamia, and order Filices.

ACT, in the language of the English universities, denotes the thesis defended in public by candidates for degrees. For degrees in arts, it is denominated a philosophical act; for those in divinity, a theological act. At Cambridge, the appellation of *commencement* is given to the same solemnities.

ACT, in dramatic poetry, denotes the parts or divisions of a play, in which the progress of the story is interrupted for the purpose of relieving the audience and the actors. The division into regular acts formed no part of the drama of the Greeks; but the necessary pauses were filled up with choruses and similar interludes. The Romans first divided dramatic pieces into five acts, of which there are examples in the comedies of Terence, and the tragedies of Seneca; the same division has been adopted by modern writers. See POETRY.

ACT of FAITH, or *auto da fe*, in the church of Rome, denotes a solemn day, appointed by the Inquisition, for the punishment of those convicted of heresy, and the absolution of those who have been acquitted of that charge. The day fixed for this purpose usually falls on some great festival. See INQUISITION.

ACTA DIURNA, or ACTA POPULI, is the name given to a Roman news-paper, which, under the authority of government, detailed such occurrences as usually appear in similar periodical works of modern times. The following extract from Petronius, is a specimen:

" On the 26th July, a slave was put to death for uttering disrespectful words against his master.

" On the same day, a fire broke out in Pompey's gardens; it began during the night, in the steward's apartments."

ACTÆA, herb Christopher, or Baneberries, a genus of plants belonging to the Polyandria class.

ACTIAN GAMES, in *Roman Antiquity*, were instituted by Augustus, in memory of the victory obtained over Mark Antony at Actium. They were celebrated in honour of Apollo every fifth year.

ACTIAN YEARS, called also the era of Augustus, commenced at the time of the battle of Actium.

ACTION, in its general acceptation, denotes the exertion of power, and is usually employed in the same sense with *act*, although some grammarians apply the first to common or ordinary transactions, and the last only to such as are remarkable; and others suppose that the former properly belongs to the power that acts, while the latter has a reference to the effect produced.

ACTION, in *Law*, is a suit or process in a court of justice, and is employed in the same sense as it was by the Romans, from whom the phrase is derived.

ACTION, in *Mechanics*, denotes either the exertion which one body or power produces upon another, or the effect which is the result of that exertion. See MECHANICS.

ACTION, in *Oratory*, is the accommodation of the countenance, voice, and attitudes of the body of a public speaker, to the emotions of the mind, or to the subject on which he addresses an audience. See ORATORY.

ACTOR, in the drama, is one who represents some part or character on the stage. Among the Greeks, with whom dramatic exhibitions originated, a simple chorus only, who sung hymns in honour of Bacchus, constituted the whole entertainments. A declaimer, who recited the adventures of heroes, was introduced by Thespis, for the sake of variety. Æschylus changed the declamation into the form of dialogue between two persons, and Sophocles added a third, that the performance might assume a more natural aspect. To this number, the actors in the Greek drama were limited; and the Romans adopted the same rule in tragedy. In comedy, the number of actors was not restricted. In modern times, the number is regulated by the nature and incidents of the piece to be performed.

Among the Greeks, actors were greatly respected and highly honoured. The Roman actors were degraded from their rank as citizens, and, in a great measure, excluded from society; and it is curious to observe, that a similar diversity of public opinion prevails in modern times. In Britain, the degree of respectability attached to the profession of an actor, depends on his moral character; but in France, actors are despised, as they were formerly at Rome.

ACTRESS, a woman who performs a character on the stage. Actresses were not known among the ancients; for female characters were performed by men, who wore masks for the purpose.

It is supposed that female actors first appeared on the English stage in the time of James I.; for it is recorded, that his queen performed a part in a pastoral; but professional actresses were probably first iutroduced during the licentious reign of Charles II. At that period, female performers were regarded as persons of infamous character; but, in the present day, the same remark is here equally applicable as to actors; for the degree of respect in which they are held corresponds with the propriety of their moral conduct,

ACTS OF THE APOSTLES, the name of one of the books of the New Testament, which contains the history of the Church during the first 30 years after the ascension of Christ, to the year 63. It was written by St Luke, and dedicated to Theophilus; to whom also he addressed his gospel. It contains the accomplishment of several promises made by Christ to his followers, and a beautiful representation of the manners of the primitive Christians; it is written in purer Greek than some of the other books of the New Testament: it was allowed to be canonical by the council of Laodicea; and, in all subsequent ages, this has been universally admitted. See SCRIPTURES.

ACUNA, CHRISTOPHER D', a Spanish Jesuit, born at Burgos, and, while in his 15th year, admitted into the society; in 1612, was employed as a missionary in South America; and, under the aus-

Acupuncture || Adam.

pices of the Spanish government, explored the great river Amazons, from its source to its junction with the Atlantic ocean. Soon after his return to Spain in 1640, he published an account of the discoveries of his voyage on this magnificent stream. This voyage occupied ten months, from the time he left Quito till he reached Para, at the mouth of the river. This book was suppressed by the Spanish government, to prevent, it is supposed, the Portuguese, who had become masters of the Brazils, and the regions contiguous to the river Amazons, from deriving any advantage from the information which it contained. A French translation was afterwards published.

ACUPUNCTURE, which signifies pricking with a needle, is a surgical operation, not unusual in Japan, China, and some other eastern countries. It is performed by pricking the parts affected with a silver needle. This operation is employed in head-ach, lethargy, and many other diseases, and seems to be analogous to the operation of scarifying and cupping in European countries.

ADAGIO, in *Music*, is a term which signifies, that the passage thus marked should be performed in slow time; when the word is repeated, the movement is to be slower; when it is used as a substantive, as, "to play an adagio," it is expressive of a slow movement.

ADAM, the first man of the human race, was formed by God on the sixth day of the creation. The etymology of the name has often exercised the ingenuity of the learned; and it has been variously traced to words in the eastern languages which signify *red earth*, *to resemble*, *to be beautiful*, and *to be first*. Adam was made of the dust of the earth, and God *breathed into his nostrils the breath of life*. The garden of Eden, or paradise, in which grew every thing that could delight the eye, or was necessary for subsistence, was prepared for his reception. In this garden all the inferior animals which had been created were assembled. God gave Adam dominion over them, and made them pass before him, to receive names according to their nature and kinds. But Adam was still without a companion: to supply this defect, God cast him into a deep sleep, took a rib from his side, and out of it formed a woman. When Adam awoke, and the woman was presented to him, he knew her to be bone of his bone, and flesh of his flesh; on which account she was called *woman*, expressive of being taken from man. Our first parents being created in the image, and after the likeness of God, were originally in a state of innocence and purity. Placed in the garden of Eden, under the divine favour, they were permitted to enjoy all the fruits which it yielded, excepting the fruit of the "*tree of the knowledge of good and evil*," which they were commanded not to touch, under the sanction of being subjected to toil and pain, and death itself. The woman, deceived by the persuasive insinuations of the tempter under the form of a serpent, seduced her husband; and by eating the forbidden fruit, they were both guilty of transgressing the divine command. They had now lost their innocence; their eyes were opened; they were ashamed of their nakedness; and, overwhelmed with conscious guilt, they attempted to withdraw from the presence of God, and vainly sought to conceal themselves from the all-seeing eye of the Almighty. The threatened punishment was pronounced. The man was doomed to toil and sorrow; the woman, to subjection to her husband, and to suffer the pains of child-bearing; and both became liable to death. God prepared for them the skins of beasts as a covering, drove them from paradise, and, on the east side, placed "*cherubims and a flaming sword, which turned every way to keep the way to the tree of life*." Adam now called his wife *Eve*, which signifies *life*, because she was to be the mother of all mankind. The offspring of Adam mentioned in Scripture consisted of three sons, Cain, Abel, and Seth, the latter of whom was born to him while he was in his 800th year. Adam died at the age of 930 years.

Adam.

The traditionary history of Adam, as it is preserved in different countries, abounds with fable and extravagance. While some ascribe to him incomparable beauty, others suppose that he was of the most gigantic stature; and on the summit of Adam's Peak, the loftiest mountain of Ceylon, the mark of a foot of extraordinary magnitude, which is said to be that of Adam, is shewn to this day; and this mountain is noted, in the traditions of the inhabitants, as the residence of our first parents. Of the knowledge of Adam, it is asserted that he was profoundly skilled in all sciences and arts; that it exceeded the knowledge of Moses, Solomon, and even excelled that of the angels themselves. Concerning the burial-place of the progenitor of the human race, great diversity of opinion prevails. Noah, according to some, placed the body of Adam in the ark, and his grandson, Melchisedech, deposited it in the earth on mount Calvary at Jerusalem; others think that it was interred in the cave of Machpelah; and the Arabians assert that he was buried near Mecca.

ADAM, Robert, an eminent architect, was the second son of William Adam of Maryburgh in Fife, and was born at Edinburgh in 1728. Mr Adam, the father, has left some respectable specimens of his genius as an architect, in Hopetoun-house, and the Royal Infirmary at Edinburgh, which were erected from his designs. To this fortunate circumstance, perhaps, young Adam was indebted for the first bias to those studies in which he afterwards obtained such high celebrity. During the time of his education at the university of Edinburgh, he had an opportunity of associating with some of the most distinguished literary characters of the age. Having directed his thoughts to the study of architecture as a profession, Mr Adam visited the Continent in 1754, for the purpose of extending his knowledge and improving his taste; and he resided three years in Italy, where he surveyed and studied the magnificent specimens of architecture which are still exhibited even in the ruins of the public edifices of ancient Rome. In tracing the progress of architecture, and the kindred arts among the Romans, Mr Adam perceived that they had suffered a visible decline previously to the time of Dioclesian; but in contemplating the design and construction of the public baths at Rome, which were erected by that emperor, he was convinced that his munificence and

Adam.

liberal encouragement and patronage of the fine arts had revived a better taste for architecture, and had produced artists who were capable of imitating a purer and more elegant style; and while he admired the magnificent structures which afforded such ample proofs of the extent and fertility of genius of the artists from whose designs they had been executed, he was anxious to see and study whatever remains might yet exist of those masters whose works present the most striking monuments of an elegant and improved taste. With this view he undertook a voyage to Spalatro in Dalmatia, to examine the private palace of Dioclesian, to which that emperor retired, when he resigned the government, in the year 305, and which was his residence for nine years previously to his death. Accompanied by Clerisseau, a French artist, and two experienced draftsmen, Mr Adam sailed from Venice, in July 1754. On his arrival at Spalatro, he found that the palace had sustained much from the injuries of time, but it had suffered more from the dilapidations of the inhabitants, and even the foundations of the ancient edifice were covered with modern buildings. The jealous vigilance of the government soon interrupted their labours, from a suspicion that their object was to view and make plans of the fortifications; but through the friendly mediation of General Graeme, the commander of the Venetian forces, they were permitted to proceed in the undertaking; and having resumed their labours, in five weeks plans and views of the fragments were finished, from which perfect designs of the entire building were executed.

Mr Adam returned to England, and soon rose to considerable professional eminence. In 1762, he was appointed architect to the King; and in the succeeding year he published his splendid work, containing engravings and descriptions of the ruins of the palace of Spalatro. In 1768, he was chosen to represent the county of Kinross in Parliament; at the same time he resigned his office of architect to the King. In the year 1773, in conjunction with his brother James, whose eminence as an architect was also considerable, he presented to the public another splendid work, consisting of plans and elevations of public and private buildings, which were constructed from their designs. Among these are Caen-wood, the seat of Lord Mansfield; Luton-house, in Bedfordshire, belonging to Lord Bute; the new gateway of the Admiralty-office; the Register-office at Edinburgh; and many others, which have been universally admired, as excellent specimens of elegant design and pure taste. The Adelphi Buildings, in London, are also striking monuments of the fertile genius of the Messrs Adam; but so extensive an undertaking was too great for private citizens, and therefore proved an unsucessful speculation. The unlimited extent of Mr Adam's invention is not less obvious in those edifices which have been more lately erected from his designs. Those parts of the New University of Edinburgh which have been completed, bear ample testimony to this remark; and those who admire the rare union of perfect symmetry and elegant disposition of parts, united with inexpressible beauty and lightness into one whole, will find this happy combination fully exemplified in the Infirmary at Glasgow. Mr Adam's genius and refined taste for architectural design continued unimpaired to the last year of his life. In the year preceding his death, the designs of eight great public works, and of twenty-five private buildings, various in style, and beautiful in composition, were the fruit of his labours. The powers of Mr Adam's genius were not limited to the external decoration of buildings. They were exercised with similar effect in the internal arrangement and disposition of the apartments, as well as in adding variety, elegance, and beauty to the ornaments of ceilings and chimney-pieces. It will scarcely be doubted, that the improved taste which now generally prevails in the public and private edifices of this country, is in no small degree indebted to the pure and correct style introduced by Mr Adam. His talents extended beyond the line of his own profession; for, in his drawings in landscape, he exhibited a richness of composition, and an effect of light and shadow, which have been seldom equalled. Mr Adam died in March 1792, in the 64th year of his age. The elegant buildings, public and private, which have been erected in different parts of the kingdom from his designs, are lasting monuments of his genius and taste; and the natural sweetness of his manners, united to the excellence of his moral character, secured to him the affection and regard of his friends, and the esteem of all who had the happiness of enjoying his acquaintance.

Adam's-Bridge || Adams.

ADAM'S-BRIDGE, a ridge of rocks and sand-banks, which stretches from the north coast of Ceylon to the coast of Coromandel.

ADAM's-PEAK, or Hamaleel in the native language, a lofty mountain, of a conical form, in Ceylon, on which it is supposed the first man was created. This mountain is seen at the distance of 40 or 50 leagues; the summit is clothed with wood, and terminates in a plain, part of which is occupied by a lake, which is the principal source of the larger rivers of the island. It is held in great veneration in the East; is a great resort of pilgrims from all parts of India; and, for performing their devotions, chapels are erected in places which are only accessible by means of chains and ropes attached to the rocks.

ADAMANTINE SPAR, a mineral substance, which in its composition approaches nearly to that of emery, and, when reduced to powder, is applied to the same purposes of polishing hard bodies. See Mineralogy.

ADAMI POMUM, or Adam's Apple, in *Anatomy*, a protuberance in the anterior part of the throat, formed by the projection of a cartilage, and whimsically supposed to have been produced by part of the forbidden fruit sticking in Adam's throat.

ADAMS, in *Geography*, a township in the state of Massachussets, 140 miles N. W. from Boston, in North America, which is remarkable for a romantic natural bridge over Hudson's Brook, in the northern part of the district. This stream has excavated a channel for itself in a bed of white marble; and the projecting rocks form a bridge of fifteen feet in length, ten in breadth, and sixty feet above the surface of the water.

Adamson. ADAMSON, Patrick, a learned Scottish divine and poet, whose history exhibits a striking instance of the vicissitudes of life, of elevation to the highest dignity in the church, and of depression to a state of poverty and want, was born in 1536, in Perth, where he finished the early part of his education, and afterwards studied philosophy at the university of St Andrew's. In 1566, while he resided at Paris in the capacity of tutor to the son of a Scotch gentleman, the muse of Adamson celebrated the birth of James VI. in a Latin poem, in which the infant prince was panegyrised as king of France and England. The assumption of this title, even in the language of poetry, gave offence to the French court. He was arrested, thrown into prison, and detained six months in confinement. Through the intercession of the Scottish Queen he obtained his liberation, and retired to Bourges, where he lay concealed during the dreadful massacre of St Bartholomew, when the demon of persecution raged with the most relentless fury in France. Immured, as he himself expresses it, for seven months in a sepulchre, his mind was actively occupied; for, during this period, he composed a Latin tragedy, and a poetical paraphrase on the Book of Job in the same language. He returned to Scotland in 1573; and being admitted to holy orders, he was appointed minister of Paisley.

The struggle between the partizans of Presbyterian and Episcopal church government, which long agitated Scotland, and finally burst forth into the flames of civil war, had now commenced; and Adamson, whether from ambition or versatility of opinion, had his full share of the miseries which were thus entailed on the kingdom. In the General Assembly which met in 1575, he took an active part in the deliberations concerning ecclesiastical jurisdiction; and he was one of the commissioners chosen to report its proceedings to the Earl of Morton, regent of Scotland. About this time he was appointed chaplain to the regent; and soon after, when the see of St Andrew's became vacant, he was elevated to the archiepiscopal dignity. This high promotion seemed to increase the rancour and violence of the Presbyterian party, to which he was now opposed. Various charges were brought against him, as being the adviser of the oppressive and tyrannical measures which were adopted towards those who maintained that form of church government; and although he came under a humble submission to the General Assembly, the persecuting spirit of his enemies was not abated. Even circumstances in themselves of trivial import, and which would have attracted no notice in a more discerning age, were magnified into serious offences. A poor old woman, who had recommended a remedy which proved beneficial in a severe disorder under which the archbishop laboured, was charged with witchcraft, and thrown into prison; and having found means to escape, she was, at the end of four years, again apprehended under the same charge, condemned, and brought to the stake.

In 1583, during a visit of King James to St Andrew's, the archbishop distinguished himself greatly by preaching before the learned monarch, as well as by his success in a public disputation in the royal presence. Having become a favourite with James, he was appointed embassador to the English court; and both in his diplomatic and clerical character, he seems to have laboured assiduously in promoting the interest of his master in his expected succession to the crown of England. His sermons, which were remarkable for eloquence, attracted great crowds to the places where he preached; and according to the usual practice of the times, mixing the praises of his prince with religious instruction, he succeeded in impressing the minds of the English with such favourable sentiments of the Scottish King, that the jealousy of the prudent Elizabeth was awakened, and he was prohibited from entering a pulpit during his residence in her dominions.

The return of the primate to Scotland was followed by a short repose. In a provincial synod which assembled at St Andrew's in 1586, he was charged with exercising episcopal functions, in opposition to former decrees of the church; and sentence of excommunication was pronounced against him. An appeal to the King and States failed in obtaining any mitigation of his sentence; and the clamours and irritation of the populace became so violent, that he was not secure from personal injury. In consequence of a submissive apology presented to next General Assembly, he was absolved from the excommunication; but two years only elapsed when he was again harassed with prosecutions. He had fallen under the displeasure of the King; a fresh appeal, in Latin verse, accompanied with poetical paraphrases of the Books of Jeremiah and Revelations, which promised to be the most successful way of moving the compassion of that pedantic monarch, had no effect; and the archbishop, being now deprived of the revenues of his see, was reduced to such poverty, that he was actually supported by the charitable contributions of his friends till his death in 1592.

The character of this prelate, as it is drawn by the hand of a friend and an enemy, presents very different features. While in the sunshine of royal favour, it seems probable that he did not at least discourage the tyrannical measures of an arbitrary government. He was deficient in that vigour and decision of mind which are always the surest foundation of consistency of conduct, but especially in the turbulent times in which he lived. His learning was respectable; he was an eloquent and popular preacher; and his versions of different books of Scripture afford ample proofs of his facility in the composition of Latin poetry. Mr Wilson, an advocate, who was his son-in-law, and the editor of his *Poemata Sacra*, or Sacred Poetry, has pronounced an extravagant panegyric on the archbishop. "He was," says he, "a miracle of nature, and rather seemed to be the immediate production of God Almighty, than born of a woman."

Adana. ADANA, a town of Natolia in Asia Minor, which is adorned with a fine bridge and splendid fountains, and enjoys an agreeable and healthy climate. The surrounding country is rich and fertile, producing corn, fruits, and wine in abundance. Adana is 30 miles N. E. from Tarsus.

ADANSONIA, Ethiopian sour-gourd, or African cabbage-tree, a genus of plants belonging to the Monadelphia class.

ADAR, the name of one of the Hebrew months, corresponding with the end of February and beginning of March, the 6th month of their civil, and the 12th of the sacred year. A 13th month, called second *Adar*, is added every third year, to make up the annual deficiency of eleven days in the lunar year.

ADDER, or VIPER. See COLUBER, OPHIOLOGY, *Index*.

ADDER, *Sea*, a species of fishes under the genus Syngnathus. See ICHTHYOLOGY, *Index*.

ADDISON, JOSEPH, one of the ornaments of English literature, was the eldest son of Launcelot Addison, dean of Litchfield, and author of several respectable publications. He was born at Milston in Wiltshire, on the 1st of May 1672. At the Charter-house he formed an acquaintance with Sir Richard Steele, which continued through life, and produced one of the characteristic features of his literary history. In the year 1687, he entered Queen's College, Oxford, being only fifteen years of age, but quite competent, by his attainments and industrious habits, to avail himself of whatever advantage an university presented to his ambition. Here he wrote some Latin verses on the inauguration of King William, which procured him the patronage of Dr Lancaster, then one of the fellows, and afterwards provost of this college. By his interest, Addison was elected into Magdalen College, where he obtained, in 1693, the degree of Master of Arts. He continued to cultivate Latin poetry with assiduous partiality, to the improvement, no doubt, of his classical taste, but little conducive to originality of sentiment or boldness of fancy; qualities in which his muse remained defective to the end of his poetical career. There are few men who have not rather encumbered natural perfections, by assuming the garb of antiquity, than enhanced their superiority by the acquisition. Addison is not an exception. Even the mightier genius of Milton struggles with a foreign attire; and so, probably, would Homer or Virgil, had they affected the appearance of a generation a thousand years older than their own.

In his twenty-second year, Addison ventured to publish some English verses addressed to Mr Dryden, whose approbation was, perhaps, more the effusion of complacency, than the result of just criticism. In a translation of the 4th Book of the Georgics, printed in that poet's Virgil, Addison was more successful. An "Essay on the Georgics," that accompanies it, exhibited him to some advantage as a prose writer; a character on which alone his reputation with posterity is founded. The "Account of the greatest English Poets," soon followed. This poem has some happy lines, but does not indicate great depth of judgment: The extraordinary omission of Shakespeare and Otway in the list, is still less pardonable. Till lately it had been believed, that the person to whom Addison inscribed this work, indicated by the initials H. S. was Dr Henry Sacheverel, of political notoriety. This, however, is a mistake. The friend was, indeed, a Henry Sacheverel, but one far less known to fame.

Addison's poetry was not at war with prudence. He shewed sagacity in using it towards the promotion of his interest. His inspiration, therefore, is somewhat problematical, since worldly wisdom is not held a companion of the muses. Lord-keeper Somers, and Montague, afterwards Earl of Halifax, shared in its eulogiums, and befriended the author. The former procured him a pension of L.300, which enabled him to undertake a visit to the continent. Previously, however, he had relinquished the intention of entering the church, in which his advancement might have been confidently expected. On his travels he wrote his famous epistle to Halifax, and commenced his still more famous tragedy of Cato. It was in Italy that the spirit of Addison was tuned to the praise of liberty, so congenial to the constitution of his countrymen, at that time boasting the recovery, or at least the possession of a free government. Well might he say,

> Thee, Goddess, thee, Britannia's isle adores;
> How has she oft exhausted all her stores,
> How oft in fields of death thy presence sought,
> Nor thinks the mighty prize too dearly bought!

But it is one of the consequences of the blessing, that certain perpetuity is denied to the possessors of official dignity. This Addison found to his cost before he returned home. His friends, on the death of King William, were removed from power; Halifax was impeached by the Commons, and his own pension was discontinued. This was the only time of his life in which he experienced an approach to poverty. The grievance taught him to set a higher value on money than, it has been idly imagined, is consistent with greatness of character. They who object to the estimate, are not aware of the misery from which pecuniary means have the power to redeem; or that the magnanimity which is in alliance with rags and hunger, would have but a sorry chance for their admiration.

A ray of hope unexpectedly beamed upon Addison in 1704, and pointed the road to affluence. Godolphin, the Lord-treasurer, at the instigation of Lord Halifax, employed him to celebrate the battle of Blenheim. The immediate reward of his poem, *The Campaign*, was the appointment of a commissioner of appeals, in which he succeeded the illustrious John Locke. Other advantages followed in train. In 1706, he was chosen Under-secretary of State to Sir Charles Hedges; was retained in this office by the Earl of Sunderland; went over to Ireland in 1709, as secretary to the Marquis of Wharton; and obtained from the Queen the place of keeper of the records in that kingdom, with an augmentation of the salary annexed to it. For this last favour he was indebted to the recommendation of the Duchess of Marlborough, to whom he had prudentially enough, but with little consideration of taste, inscribed his poem of Rosamond.

Addison's attachment to Whig principles did not prevent an honourable friendship between him and Swift, so violent for Toryism. These men could esteem each other through the medium of their political dissentions, though, at last, their increasing zeal precluded intimacy. Some of their correspondence is preserved, and is mutually kind and respectful. Pope, somewhat younger than Addison, was not quite so indulgent, and on the whole, perhaps, had less reason. The connection with Steele was of most consequence to literature.

This gentleman commenced the Tatler during Addison's residence in Ireland. The publication, which originated without his knowledge, having, however, indicated its author, by the insertion of a criticism with which Steele had been entrusted, acquired his powerful and continued aid. To this succeeded the Spectator, which commenced on the 1st of March 1711. Addison's papers in the Spectator are marked by one of the letters in the word *Clio*, and in the Guardian, another periodical work in which he was afterwards engaged, by a hand; his papers in the Tatler have no such distinctions.

The success of Cato, which appeared in 1713, exceeded the author's hopes; Whigs and Tories uniting to applaud it,—the former, because it yielded fuel to the flame of liberty; the latter, because they *would not* be mortified by the high-toned triumphs of their opponents. Fashion and habit now enjoin its commendation, as an evidence of good taste, though the morality of the Christian religion condemn the pride of its hero, and criticism object the poverty of its subordinate characters, and the unsubdued dulness of its story. Lofty sentiments, couched in glowing language, impose on minds aspiring after the *sublime* of life; but reason, if unbiassed by excellencies in the representative republican, abates the credit of the delusion. In our sober moments, we cannot behold a man " lord it so," over the best and most amiable feelings of our nature, without entertaining a degree of indignation at his cold blooded arrogance, and something like contempt of those who can so far estrange themselves from common sense and humanity, as to hail such conduct " godlike."

About the same period, Addison, thoroughly wedded to his political creed, and suffering for it in the loss of his places, produced the *Whig Examiner*, and some pamphlets, in defence of his party. The *Freeholder*, also a political paper, appeared somewhat later. These have lost their interest in the lapse of years, but the purity of style, conciseness of thought, and felicity of allusion which characterise Addison, are no where in his writings more discernible.

On the accession of George I., his political labours were rewarded by the office of secretary to the Earl of Sunderland, Lord-lieutenant of Ireland. This he soon gave up to become a Lord of Trade; and, in 1717, he reached his highest elevation as one of the principal Secretaries of State, an honour, however, which his ill health did not permit him long to enjoy. He resigned it on a pension of L.1500, intending to occupy the remainder of his time in literary pursuits which might conduce to human happiness and improvement.

The chief production of his retirement was an essay on the " Evidences of the Christian Religion," in which he avowed his stedfast belief. He died on the 17th of June 1719, when entering on his 54th year, and left an only daughter by the Countess of Warwick, whom he married in 1716. Uncontradicted report has assigned much unhappiness to this union, occasioned by the lady's conceit of her superior rank, which even the singular worth of her husband could not restrain into decency. Yet whether, in common style, from a wish to make things look better than they were, out of real affection, or the distinguishing benevolence of a dying man, Addison mentions her in his will with the greatest tenderness and respect. An incident in his departing struggle, has always been noticed with admiration. Finding his end near, he sent for Lord Warwick, his wife's son, by a former marriage " a youth," as Dr Young modestly expresses it, " finely accomplished, but not above being the better for good impressions from a dying friend." The interview was short. After a pause, the young man said, " Dear Sir! you sent for me, I believe: I hope that you have some commands; I shall hold them most sacred." To which Addison replied in a soft voice, whilst he grasped his hand, " SEE IN WHAT PEACE A CHRISTIAN CAN DIE," and soon expired.

Addison's talents were not ready; they sought time, and retirement, and indulgence. He was unfit, therefore, for the public duties of his ministerial situation, or, at least required unusual conditions for their fulfilment. But we must not ascribe the deficiency to a distrust in his own abilities; this is a common mistake. As to Addison, it is irreconcileable with the fastidiousness of his taste, which was undoubtedly subservient to the preservation of the consequence he had already acquired; and it is alike disproved by the unaccommodating tone of his political publications, and the easy gaiety with which he could converse where his influence was allowed to be supreme.

His writings, which seem a fair reflection of his character, claim respect rather than elicit admiration; they scarcely ever need indulgence. Their morality is polite, not authoritative. They recommend the kindly affections and the graces which every one applauds; and they dissuade from vices and rudenesses which every one condemns. Addison and his reader, accordingly, are always on good terms. Even his religion is agreeable—to the profligate, because it discloses some excellencies in their heart, which need but a little encouragement to retrieve and surpass their transgressions—to the pure in their own eyes, and wise in their own conceit, because it is readily available to a dear delusion, and inculcates no self-denial—to all, because its simplicity solicits the meanest understanding, its specious importance employs the highest, whilst it garnishes the path of duty with so many fruits and flowers that neither fancy nor the heart desires to wander.

His style abounds in beauties, which, though not superlative, never fail to attract. It is easy, perspicuous, concise, elegant,—free from the blemishes of his time, indecency, antithesis, and conceit,—but free also from the wild and loftier excellencies which marked an earlier period of our literature; it wants soul, and it wants passion,—it has mind, indeed, always, and sometimes feeling, but the former is unruffled to wearisomeness, like the sea in a calm, and the latter is so nicely adjusted by rule and compass, that we never have a moment's interest or apprehension about its issue. Addison frequents the court, the drawing-room, the tavern,—is familiar with all, paints all so faithfully, so naturally, so humorously, that we seem to be one in every party as much as himself, and to have a common right to judge, admire, dislike, laugh, in short to retain all the incontestible privileges of our own fire-side. But he rarely quits the city, and when he does, it is but to visit the garden or the meadow, where every thing is regular, nicely trimmed, and well fenced, and constantly reminds us of the encroachments which industry and skill have made on the dominions of nature. Of wildernesses, forests, cataracts, the Alps, or the Andes, he has no knowledge; storms, whirlwinds, and earthquakes, never disturb his creation: even his visions and dreams have the method and monotony of civilization; his calamities and prosperities, his misfortunes and rejoicings, like the items in a merchant's book, are all appreciated in the pounds, shillings, and pence of Old England. On the whole, he is a writer of good sense and good manners; he instructs a little, amuses more,—he may be said to have refined our language at the expence of its strength, to have given it clearness, but to have deprived it of its elasticity and power,—he inculcates by example, perhaps the best mode for general adoption, a hesitating and cautious reserve in composition, which *may* escape blunders and absurdities, but which *must* repress vigorous conception, and stifle heart-born eloquence.

ADDITION, in *Arithmetic* and *Algebra*, is the rule by which two or more numbers or quantities are brought into one. See MATHEMATICS.

ADEL, a kingdom of Africa lying on the eastern coast of that continent, bounded by the Indian Ocean on the east, by Abyssinia on the west, and extending about 500 miles from east to west, and about 300 miles from north to south. This kingdom was formerly tributary to the sovereigns of Abyssinia; but an Abyssinian prince having escaped from the confinement to which the branches of the royal family excluded from power are doomed, found an asylum in Adel, married the daughter of the king, and erected it into an independent state. Since the beginning of the 16th century, the open warfare which then commenced has been seldom interrupted. Religious enmity has probably had no small share in continuing the struggle for conquest and power; for the Abyssinians are Christians, and the people of Adel profess the Mahometan faith, and acknowledge the sovereignty of the Grand Signior.

The temperature of the air is very considerable; rain seldom falls; and the climate is in general unwholesome. The interior districts of the kingdom are unknown to strangers: in some places, nothing is seen but extensive barren desarts; others are covered with rich soil, which produces abundance of corn, and feeds numerous herds of cattle, and, particularly, that singular variety of sheep with broad tails, some of which exceed twenty pounds weight. Some of the inhabitants are of a black, and others of a tawny complexion. Adel and Zeila are the chief towns, from which, and others on the coast, there is a considerable trade in ivory, gold dust, and valuable drugs, which are exchanged for the rich productions of Arabia and other eastern regions. Adel, the capital, which gives name to the kingdom, is in N. Lat. 8° 5. and E. Long. 44. 20. and 300 miles south from Mocha.

ADEN, is the chief town of a country of the same name near the southern extremity of Arabia Felix, and to the eastward of the straits of Babelmandel. The town is nearly encompassed with lofty mountains, from which it derives an ample supply of water by means of a splendid aqueduct. Aden successfully resisted an attack of the Portuguese in 1513; but soon after fell under the dominion of the Turks, who were dispossessed by the king of Yemen, by whom its trade was transferred to Mocha. Before this period, Aden, from its local position, had become a celebrated emporium. N. Lat. 12. 40. E. Long. 46. 13.

ADENANTHERA, Bastard Flower-fence, a genus of plants belonging to the Decandria class.

ADERBIJAN, a province of Persia, part of which is bounded on the east by the Caspian Sea. Tauris, or Tebriz, formerly the residence of the Persian monarchs, is the principal town, the trade and population of which are considerable.

ADHA, a solemn festival celebrated by the Mahometans on the tenth day of the last month of their year, on which a sheep is offered in sacrifice at Mecca, but no where else. This festival is denominated the *Great Bairam*; and, from the numerous ceremonies observed by the pilgrims in this month, it is called the *month of pilgrimage*.

ADHERENCE, action of, in the *Law of Scotland*, an action which is commenced at the instance of a husband or wife, to compel either party to return or adhere in case of desertion.

ADHESION, signifies the sticking or adhering of two bodies which are naturally separate; but is often employed to denote the force of attraction between the surfaces of two solid bodies, as the polished surfaces of glass, marble, or metal; or between a solid and a liquid, as glass and quicksilver. See AFFINITY, under CHEMISTRY.

ADIANTUM, Maidenhair, a genus of plants belonging to the Cryptogamia class.

ADJECTIVE, a word joined with a noun, and expressive of some accident, property, or quality existing in any thing, as, a *good man*, in which the adjective *good* denotes the quality of goodness in the man to whom it is applied. See GRAMMAR.

ADIPOCIRE, from two Latin words, which signify *fat* and *wax*, is applied to a substance whose properties are intermediate between these two substances. Adipocire is formed by a certain change of the soft parts of animal bodies, subjected for some time to running water, or when a great quantity of animal matters is accumulated in a moist place. It was found in abundance, when the remains of the bodies were removed from the burial-ground of the *Innocens*, in Paris, in 1787, and seems to have been generated by the great mass of animal matters, twelve or fifteen hundred bodies deposited in the same pit. See CHEMISTRY, *Index*.

ADJUDICATION, is the act of adjudging or determining the right or property of a thing, by the decision of a judge, in favour of some party. In the law of Scotland, it is an action by which a creditor obtains possession of the heritable property of his debtor, or the debtor's heir; or, it is an action by which a person possessing an heritable right, may supply any defect in that right in point of form.

ADMINISTRATION denotes, in general, the government or management of affairs, and, particularly, the exercise of distributive justice. Among ecclesiastics, it is employed to express the dispensation of the sacraments. The same word is used by the Spaniards, to denote the warehouse or magazine at Callao, and other ports in South America, in which foreign ships deposit their cargoes, on the payment of certain duties.

ADMINISTRATOR, in the *Law of England*, is a person to whom is entrusted the management of the goods of another who has neglected to appoint an executor, and who possesses similar powers. In the law of Scotland, it is applied to a person who is authorised by law to direct the affairs of another, who is incapable from age or mental imbecility of acting for himself. A father, who is empowered by law to have the charge of the persons and property of his children, during their minority, is denominated their administrator.

ADMIRAL, an officer or magistrate who presides in the court appointed for the regulation and trial of all maritime affairs, and to whom is entrusted the command of the whole or part of a navy. The origin of this high office, which has existed from a very early period, in almost every maritime state, and even the etymology of the name, are undetermined. Some antiquarians trace it to the word *amir* or *emir*, which is a general appellation among the Saracens or Arabians, for a chief ruler, governor, or commander, and, in confirmation of this opinion, assert that the name and office were introduced into Europe during the Crusades. The Sicilians, it is said, were the first, and the Genoese the next, who bestowed the name of *admiral* on the commander of their fleets. It does not appear, from the researches of antiquarians, that this name was known in England before the latter end of the long reign of Henry III. The first title of Admiral of England was given in 1387, by Richard II. to the Earl of Arundel and Surrey.

To the High Admiral, or Lord High Admiral of England, the sole management and direction of maritime affairs are entrusted. He has the command of the royal navy, the appointment of admirals and all other officers, and he possesses a civil and criminal jurisdiction in all maritime matters. But the administration of this high office has been long discontinued, and is now delegated to six persons, who are denominated Lords Commissioners of the Admiralty, and who, by statute of William and Mary, have the same power and privileges as the Lord High Admiral.

A similar officer, with extensive powers, formerly existed in Scotland; but the duties of this office fell under the cognizance of the Lords of the Admiralty for Britain, and a vice-admiral is appointed by the crown, who possesses a civil and criminal jurisdiction; and the duty of the office is executed by a deputy called the Judge-admiral, in whose court all cases connected with maritime affairs are tried.

Admiral is the denomination of the highest rank of officers in the British navy. Admirals are divided into three classes, which are distinguished by the colour of their flags, red, white, and blue; and each admiral has a vice and rear-admiral subordinate to him. The admiral carries his flag at the main top-mast head; the vice-admiral at the fore top-mast head; and the rear-admiral at the mizen top-mast head.

ADMIRALTY, court of, a supreme court, held by the Lord High Admiral, or Lords of the Admiralty, for the cognizance of all maritime affairs, whether of a civil or criminal nature. All offences committed on the high-seas, or on great rivers, below the first bridge, or on the shores of all countries subject to Great Britain, are tried in this court. In England, the Lord Chancellor appoints commissioners for the trial of all criminal cases before a jury. These commissioners are the judges of the court of admiralty. From the sentence of this court, an appeal lies to the King in Chancery.

In Scotland, the supreme court of the Judge-admiral grants commissions to admirals within certain jurisdictions to hold inferior courts; and from their decisions an appeal may be made to the supreme court.

ADMIRALTY BAY, a spacious bay on the west coast of Cooke's Straights, in the southern island of New Zealand. This bay affords good anchorage, and, on many parts of the coast wood and water can be obtained in abundance. S. Lat. 40° 37′ E. Long. 174° 54′.

ADMIRALTY ISLANDS, a cluster of between 20 and 30 islands, lying in S. Lat. 2° 18′ and E. Long. 146° 44′, which were discovered by Captain Carteret, by whom they are described as exhibiting a rich verdure of lofty and luxuriant woods, interspersed with plantations, in which appear groves of cocoa-nut trees, and houses of the natives, who seem to be very numerous. The state of the ship prevented him from landing, but the climate, which seemed to be the same as that of the Moluccas, is favourable for the production of spices.

ADMIRATION is that emotion of the mind which is produced by the contemplation of superior and rare excellence, as, uncommon wisdom or ingenuity.

ADNOUN is a word synonimous with adjective, because it is added to or conjoined with a noun.

ADOLESCENCE, denotes that period of life between infancy and manhood, which is usually reckoned between 15 and 25 or 30 years of age. The period of adolescence among the Romans was reckoned from 12 to 25 in males, and from 12 to 21 in females.

ADOM, a small state or principality of the Gold Coast in Africa. The country, which is rich and populous, abounds in corn and fruits, and feeds numerous herds of cattle. Gold and silver collected in the interior, form articles of trade, and a considerable revenue was formerly derived from the negro slaves brought from the northern parts of Africa.

ADONIA, solemn feasts which were celebrated by many eastern nations, in honour of Venus, and in memory of Adonis, with whom she was deeply enamoured. Adonis was the son of Cynaras, king of Cyprus, was slain by a wild boar, and changed into a flower of a blood-red colour: but, according to another fable, he was a beautiful shepherd, and, after being killed by the boar, was converted into a river, the waters of which, during the annual inundations, were stained with a red earth which was washed from the contiguous soil, and were supposed to be tinged with blood from the wound bleeding afresh. According to one account of these festivals, they lasted two days; one of which was occupied in expressions of grief, by weeping, wailing, tearing the hair, and beating the breast; and the other was devoted to rejoicings, in which the praises of Adonis were celebrated, as if he had been restored to life. But, according to another explanation of these ceremonies, the days of mourning and joy constituted two distinct festivals, kept at different periods of the year, with an interval of six months. From this consideration, it seems probable, that the fabulous history of these festivals is connected with certain natural occurrences, as the change of seasons, or periodical inundations, which are not unusual in eastern countries. Might not this view afford some light to the researches of antiquarians in tracing their nature and origin? The Egyptians, it is said, observed festivals of a similar character, to commemorate the sickness, recovery, or death of Osiris; by some, their origin is derived from the slaughter of the first born in Egypt in the time of Moses; and the prophet Ezekiel refers to something of the same kind, when he says, chap. viii. that he saw women sitting in the temple, and weeping for Adonis.

ADONIS, Birds or Pheasant's Eye, a genus of plants belonging to the Polyandria class.

ADONISTS, a name applied to certain divines or critics, who assert, that the natural points of the word Jehovah are not usually annexed to that word, but the points belonging to Adonai; because, it is said that the Jews were prohibited from pronouncing the word Jehovah, for which Adonai was substituted and read. To the Adonists are opposed the Jehovists, who maintain a contrary opinion.

ADOPTION, the act by which a person receives another into his family, acknowledges him for his son, and admits him to all the privileges of that relation. The indulgence of the natural feeling of leaving a name and memorial, has introduced the practice of adoption into all countries; and, that it might not be indiscriminately followed, laws and certain formalities have been established for its regulation. This custom prevailed greatly among the ancient Greeks and Romans. It was requisite that the person who adopted should be without children, should be advanced in life, and, at least, 18 years older than the son to be adopted, that the new relation might appear natural.

Adoption, or *filiation*, as it was called among the Greeks, was permitted to such as had no offspring of their own, excepting those who were incapacitated from managing their own affairs, as idiots, infants, slaves, &c. When the ceremony of adoption was performed, the name of the adopted was enrolled in the tribe of his new father. To give it more solemnity, this enrolment took place on a particular festival; and, by a law of the Lacedæmonians, the ceremony was partly performed, or at least received confirmation, in presence of their kings. The adopted, possessing all the privileges of children, were bound to observe all their duties; they ceased to have any claims of inheritance on the family which they had left; and they were not permitted, by the laws of Solon, to renounce their adoption, without having offspring to remain as substitutes. A law of the Athenians prohibited the person who adopted another from marrying, without permission from the magistrate; and, in case of children by marriage, the adopted shared equally with them in the inheritance.

Two forms of adoption were observed among the Romans; the one in presence of the prætor, when the natural father resigned all authority over his son, and expressed his consent to his being adopted by another. The other mode was practised during the republic, at an assembly of the people, and afterwards by an order from the emperor; and in this case, the party adopted was already free.

Among the Mahometans, adoption forms no impediment to marriage. The ceremony of adoption among the Turks consists in drawing the adopted person through the shirt of the adopting father; and hence the phrase which expresses adoption among that people, *to draw another through my shirt*. The resemblance of this ceremony is traced to the practice of the Hebrews, as in the case of Elijah adopting Elisha for his son and successor, and communicating the gift of prophecy, by covering him with his mantle, and then by letting it fall while he was ascending in the chariot of fire. The exchange of girdles is a simple form of adoption equally valid, which in modern times is sometimes practised among the Turks, Greeks, and Armenians.

Adoption is regulated by law among the Gentoos; and the ceremony is performed in presence of the magistrate, by giving gold and rice to the father of the child to be adopted, which are the symbols of a purchase. But no person having a son or grandson, &c. or whose brother has a son, is permitted to adopt.

Adoption by arms, was when a present of arms was made by a prince to any person on account of his merit and services. The obligation laid on the adopted son, required him to defend and protect the father from all kinds of injury and insult. From this practice the ceremony of dubbing knights, according to some, derives its origin and name.

ADORATION, an act of worship, or the external expression of the sentiments of veneration and regard towards the Supreme Being; but it refers also to a similar act performed to other objects. The word is derived from two Latin words, signifying to *apply the hand to the mouth*, or *to kiss the hand*; in allusion probably to a common custom in eastern countries of kissing the hand in token of respect and submission.

In the religious worship of the ancient Romans, adoration was performed with the head covered, and the right hand applied to the mouth; by bowing the head, and turning the body from left to right. But in the adoration of Saturn and Hercules, the head was uncovered; and this was called the Greek mode of adoration. Bowing, kneeling, and prostration, were the usual modes of adoration among the Jews; and, among Christians, this act is performed with the head uncovered. The usual posture of the ancient Christians was kneeling in private, but in the public assemblies they stood. Presbyterians have generally adopted the standing posture; while the form of kneeling is observed in the Lutheran churches. In eastern countries, it is common to take off the shoes or slippers, before entering a place of worship; and the Persians, and some other nations, direct their faces towards the sun, or to the east, in the act of adoration.

Similar marks of honour and respect were paid to persons of high rank. The Roman and Grecian emperors were adored by bowing or kneeling at their feet, touching the purple robe, withdrawing the hand, and applying it to the lips. The Persian mode of adoration, which was introduced by Cyrus, consisted in bending the knee and falling on the face, striking the earth with the forehead, and kissing the ground. In the English court, the ceremony of kissing the hand of the sovereign, as an acknowledgment of honours conferred or favours received, which is performed in a kneeling posture, may be regarded as an act of adoration of a similar character.

Adoration, in the court of Rome, is the ceremony of kissing the Pope's feet, the origin of which, it is supposed, has been derived from a similar practice among the Roman emperors. That the people might be less reluctant in this mark of respect, Dioclesian, it is said, had gems attached to his shoes; and the Roman pontiffs have the figure of a crucifix on their slippers, that the adoration paid to the Pope may seem to be transferred to Christ.

ADOUR, a river of France, which rises in the mountains of Bigorre, in the upper Pyrenees, and running in a northerly direction through Gascony, turns afterwards to the east, passes by Dax, and falls into the Bay of Biscay, below Bayonne.

ADOWA, the chief town of Tigré in Abyssinia, is situated on the declivity of a hill, on the side of a plain which is surrounded by mountains. The name, which signifies *pass* or *passage*, is descriptive of its situation, for it is the only passage from the Red Sea to Gondar. Adowa is the residence of the governor, contains about 300 houses, and has a manufactory of coarse cotton cloth, which is employed as the circulating medium in Abyssinia. N. Lat. 14° 7′ E. Long. 38° 50′.

ADOXA, tuberous moschatel, or hollow-root, a genus of plants belonging to the Octandria class.

ADRASTUS, a king of Argos, is celebrated in history as one of the seven warriors who conducted their forces against Thebes, in support of Polynices, who was excluded by his brother Eteocles from his share of the sovereign authority. Adrastus, who escaped by the swiftness of his horse, was the only one who survived the expedition. After the lapse of ten years, the sons of the seven chiefs renewed the war, and became masters of Thebes. The only leader who fell, was the son of Adrastus, for whose loss he was so afflicted, that he died of grief at Megara, as he was returning with his victorious army. The first war is celebrated by Statius, in the Thebaid; and the last, called the war of the Epigones, or descendants, forms the subject of Wilkie's Epigoniad.

ADRIAN, or HADRIAN, PUBLIUS ÆLIUS, a celebrated Roman emperor, was born at Rome, in the 76th year of the Christian era. Deprived of his father in his tenth year, he was placed under the guardianship of Trajan. He soon discovered a strong predilection for literature, in the acquisition of which he was greatly distinguished, and particularly in the knowledge of the Greek language, which was now assiduously cultivated by the learned Romans. Adrian commenced his military career in early life, and served as tribune in the army, by whom he was chosen to announce the death of Nerva to Trajan, and to congratulate him on his accession to the imperial throne. Adrian, it has been asserted, on account of some peculiarity of temper or character, or from his attachment to learning, was disliked by Trajan. But this seems little consistent with his promotion to places of high trust and confidence, which he held under that emperor. In almost every expedition which Trajan undertook, Adrian accompanied him as quæstor; and he was afterwards appointed tribune of the people, prætor, governor of provinces, and pro-consul. But if Adrian really failed in securing the attachment of Trajan, he was fortunate in obtaining the favour and influence of the Empress Plotina. Through her means, his marriage with Sabina, the Emperor's grand-niece, was accomplished; an event which probably opened the path to his future greatness. On the death of Trajan, which happened when Adrian was governor of Syria, and commander of the army, the empress, in a communication to the senate, declared that her husband had adopted him as his heir. When the news reached Adrian, he caused himself to be proclaimed emperor.

Adrian was invested with the imperial dignity in the year 117. The first act of his government was the restoration of the conquered countries to the Persians; and the remission of the enormous sum of more than L.7,000,000 sterling, in debts due to the state by individuals, cities, and provinces, acquired for him a high degree of popularity, and is commemorated in medals struck on the occasion, in which he is represented with a flambeau in his hand, setting fire to the bonds which his extraordinary generosity had cancelled. On his return to Rome in 118, a triumph, and the affectionate title of *Father of his country*, were decreed to him by the senate. But he had the magnanimity to decline the proffered honours.

Two years afterwards, Adrian visited Germany, Gaul, and Britain. To give greater security to the Roman power in Britain, he contracted the limits of his dominion; and, to restrain the irregular warfare of the native Caledonians, he constructed the celebrated wall which still bears his name. This stupendous work extended from the river Tyne at Newcastle, to the Solway Frith, a distance of 60 miles; and its remains are still visible in different parts of its course, as in the vicinity of Hexham, westward from Carlisle, and near its termination at the village

Adrian.

of Bowness. Adrian, on his return to Rome, was greeted with the title of Restorer of Britain, and medals were struck in honour of this event.

From this period to his death, he was constantly occupied in visiting the widely extended provinces of the empire. The activity of his mind was not solely confined to the political affairs of his administration; for, while he was in Sicily, he ascended Ætna to contemplate the striking appearances of that celebrated volcanic mountain; and he spent a night on its summit, that he might enjoy the glowing beauties of the rising sun. During the active and vigorous reign of this wise and prudent prince, it must ever be regretted, that the Christians had been subjected to severe persecution; and the wanton indignities, and studied insults, heaped on the Jews, are altogether irreconcileable with the generous conduct of a magnanimous conqueror towards a subjugated and depressed people. The images of swine, an animal held in abhorrence by the Jewish nation, were engraven on the gates of Jerusalem; the statues of the heathen divinities were erected in the most sacred places; and they were not permitted to revisit the holy city, excepting on one day of the year, which was fixed for the anniversary of their subjection to the Roman power.

Adrian was seized with a dropsical disorder which terminated his existence in the 63d year of his age, and the 22d of his reign. His character exhibits a singular assemblage of virtue and vice. He was generous, affable, and courteous; but, in his natural disposition, he was suspicious, envious, and cruel; capricious in his attachment, and violent in his resentment; distrusted by his friends, and dreaded by his enemies. Adrian is represented as an excellent scholar, and as a liberal patron of learning. Fragments of his Latin poetry are still extant; and a Greek poem, entitled *Alexandriad*, of which favourable specimens have been quoted by the ancients, was the production of his muse. A prose work, the history of his own life, to which the name of his freed man Phlegon is prefixed, has been ascribed to Adrian. But the following verses addressed to his soul, composed, it is said, on his deathbed, and in a strain of tender levity, have been often read and admired, and have been the subject of numerous translations and imitations by modern poets:

Animula, vagula, blandula,
Hospes, comesque, corporis,
Quæ nunc abibis in loca
Pallidula, rigida, nudula,
Nex, ut soles, dabis jocos?

Ah! fleeting spirit! wandering fire,
That long hast warmed my tender breast,
Must thou no more this frame inspire,
No more a pleasing cheerful guest?
Whither, ah whither, art thou flying?
To what dark undiscovered shore?
Thou seem'st all trembling, shivering, dying,
And wit and humour are no more?—Pope.

Adrian IV. Pope, the only Englishman who enjoyed the papal dignity, and whose original name was Nicolas Brekespere, was born at Langley, near St Albans, in Hertfordshire. His father had assumed the monastic habit in the monastery of St Albans; but his own application, whether he was urged to it by the pressure of poverty, or by motives of piety, to be admitted into the same religious establishment, was rejected. Driven from his native country by this disappointment, he fixed his residence in Paris, where he soon attained, by his assiduity and industry, considerable distinction for theological learning. Still inclined to a monastic life, he retired to Provence, became a regular clerk in the monastery of St Rufus, was afterwards promoted to the canonical order, and, by his learning, prudence, and rigid observance of the rules of the institution, was, on the death of the abbot in 1137, elected superior of the establishment. The monks beheld the elevation of a foreigner with a jealous eye, and were little disposed to submit quietly to his authority; and the Pope, anxious to secure the tranquillity of the monastery, saw that it was necessary to remove him: but holding his talents and merit in high estimation, he immediately conferred upon him the dignity of Cardinal Bishop of Alba, and afterwards the appointment of legate to Denmark and Norway, where he succeeded in converting the natives to the Catholic faith, and established the archiepiscopal see of Upsal. Soon after his return to Rome, Pope Anastasius died, and he was unanimously chosen to be his successor in the papal chair, when he assumed the name of Adrian.

Henry the Second of England, gratified to see an Englishman promoted to the holy see, appointed a splendid embassy, composed of the abbot of St Albans and three bishops, to offer sentiments of congratulation, along with many rich presents. The presents were declined; but the abbot obtained for his monastery some valuable privileges; and, in particular, an entire exemption from all episcopal jurisdiction, except to that of the see of Rome. Adrian's elevation to the papal throne brought with it much anxiety and disquietude. Political discussions with the Roman magistrates, produced an interdict from religious worship for several months, which was removed by the banishment of Arnold of Brescia, a popular leader, who was afterwards recalled, and condemned for his sedition or heresy to be burned alive. The sentence was executed, and his ashes were thrown into the Tyber, that his followers might be precluded from seizing and preserving them as precious relics. Adrian was involved in constant struggles with kings and princes, one of whom, the king of the Romans, performed the humiliating penance of holding his stirrup while he mounted his horse; and another, the king of Sicily, was excommunicated for encroaching on the territory of the church. The troubles of a short reign of four years and nine months, which terminated in 1159, although not unmarked by vigour, prudence, and dignity, drew from the dying pontiff a sentiment similar to that which is expressed by the bard of Avon;

"Uneasy lies the head that wears a crown."
Shakespeare.

Adrianople.

ADRIANOPLE, a city in the province of Romania, in the European part of the Turkish dominions, derives its name from the Roman emperor Adrian, by whom it was built or improved, stands in a plain on the banks of the river Mariza, and is encompassed by mountains. It is six or seven miles in circumference, and is surrounded by a wall. Many of the houses are low and built of mud; some are constructed of brick, in a better style. The streets are irregular, narrow, and dirty. The number of inhabitants of all nations exceeds 100,000. It contains three bazars or market-places; one of which is an arched building, half a mile in length, and divided into 365 splendid shops; a second, a mile in length, is also well provided with shops of an inferior description; and the third, in a different quarter of the city, is covered with boards, supported by a double row of massy columns, and is appropriated to the sale of works in gold and silver, jewels, and warlike instruments. The palace of the grand vizier, in the Turkish style, is remarkable for its extent and the beauty of its situation. But the chief ornaments of Adrianople are four mosques, of elegant construction and unrivalled execution, whose lofty spires, galleries resting on beautifully sculptured columns, with pedestals and other embellishments of cast brass; cupolas surmounted with gilded balls; gates of the finest marble, most exquisitely carved; magnificent porticos, and splendid fountains, present altogether one of the most impressive scenes of eastern grandeur. The Greek emperor was dispossessed of Adrianople in 1362, by the Turks, and it continued to be their metropolis till Constantinople, in 1452, yielded to the arms of Mahomet II. It is now governed by a Mullah cadi with absolute authority, is the seat of a Greek bishop, and, in times of commotion, is the residence of the Grand Signior. N. Lat. 41. 41. E. Long. 26. 27.

ADRIATIC SEA, or Gulf of Venice, an arm of the Mediterranean, which is bounded on the east by Dalmatia, Sclavonia, and Turkey, and on the west by Italy, extends from south-east to north-west about 200 leagues, and is about 50 in breadth. The temperature of the Adriatic is considerable in summer; but in the vicinity of Venice it is frequently frozen over in winter. The dominion of this sea is claimed by the Venetians.

ADUAR, a travelling village, common in eastern countries, particularly among the Moors and Arabians. The inhabitants of which it is composed dwell in waggons and tents, for the conveniency of removal from place to place, on account of pasturage for their cattle. It is said that 30,000 villages of this description exist in the kingdom of Algiers; but this is perhaps an exaggerated statement.

ADVENTURE BAY, a bay in Van Diemen's Land, near the southern extremity of New Holland, was discovered by Captain Furneaux in 1773, and was visited by Captain Cooke in 1777. The bottom of this bay is bounded by a beautiful beach two miles in length, and covered with a fine white sand thrown up by the sea, and probably produced by the decomposition of sandstone rocks which appear on different parts of the coast. The elevated land in the vicinity is clothed with thick forests. The few natives who were seen, seemed to be extremely ignorant and barbarous. Their huts were miserably constructed; and no trace of boat or canoe was observed. The animals, especially birds and insects, of rich and beautiful colours, are numerous; the only quadrupeds are supposed to be the kangaroo, and a small species of opossum; snakes and lizards are common; the sea abounds with fish; and a lake of brackish water, situated in a plain not far distant from the beach, afforded bream and small trout to the voyagers.

ADVENTURERS, a society of merchants, formed for the discovery of new territories and sources of trade; had its origin in Burgundy, and was first established at Antwerp by John duke of Brabant, about the middle of the 13th century, where it was distinguished by the appellation of the *Brotherhood of St Thomas a Becket*. This association, which was partly composed of English merchants, derived various immunities from the sovereigns of England,—the privilege of exporting wool, from Edward I. about the end of the 13th or beginning of the 14th century;—a charter from Henry VI. in 1430;—the name of *Merchant-adventurers of London*, from Henry VII. in 1505;—and the form of an English corporation from Queen Elizabeth, in 1564. Such was the monopolizing spirit of the times, that this company claimed and exercised the right of granting licences to all other English merchants for the privilege of trading in the great fairs on the continent. The sum at first demanded for this licence was only 6s. 8d.; but in the time of Henry VII. it was raised to the enormous sum of L.40. Another association had now been formed, denominated the *Merchant-adventurers of England;* their application to parliament to be relieved from this heavy imposition was successful, and it was reduced to nearly the original tax.

ADVERB, a word conjoined with an adjective or verb, and expressive of some modification in that quality or action in the words with which it is associated; as *very* rich, *highly* favoured; he walks *quickly*.

ADVERSATIVE, a conjunction, denominated disjunctive, because it separates, or sets in opposition, different clauses of a sentence; as, he is extremely rich, *but* a great miser; in which *but* is the adversative conjunction.

ADULA, the ancient name of one of the summits of St Gothard, one of the Swiss Alps, which gives origin to the river Rhine.

ADULARIA, a crystallized and transparent variety of felspar, derives its name from the mountain Adula, which affords fine specimens of this mineral. See Mineralogy.

ADULTERATION, from a word signifying to corrupt, is the act of debasing or corrupting any substance by an admixture of something of inferior value. Adulteration of the necessaries and luxuries of life is subjected to the penalties of fine and imprisonment. Adulteration of the *coin* is effected by forging another stamp or inscription; by increasing the proportion of alloy with the gold or silver; by substituting a different metal; or by diminishing its size, by clipping, filing, &c. This offence is severely punished among all nations. By the Egyptians, the offender had both hands cut off; and by the Romans, at one period, he was thrown to wild beasts. In the time of Constantine, it was declared to be treason, as it is at the present day in Britain.

ADULTERY, the violation of conjugal fidelity, by an unlawful connection between a married and an unmarried person, or between two married persons. The different degrees of criminality or moral turpitude, in the estimate formed of this offence by different nations, and by the same nation at different periods of barbarism and refinement, have produced a remarkable diversity in the penal enactments against it. Among early nations, the severest punishment was inflicted. It was punished by death among the Jews; by death or mutilation, by the loss of nose, eyes, or ears, among the Greeks; by a similar mutilation, at one period, among the Romans, and at another period by death. By the older laws of almost all European nations, the punishment was also capital; but the laws have become obsolete, or are greatly mitigated. In England, death, banishment, mutilation, and, in the present day, a pecuniary fine, have been the different punishments annexed to this crime. In Scotland, in the 16th century, open cohabitation or *notour* adultery, was punished by the forfeiture of goods; but it was soon after rendered capital; and in the succeeding century, several offenders of this description were actually executed. In cases of simple adultery, pecuniary damages are awarded, as in England. The injured party may obtain a divorce by act of parliament in England, and by an action in the commissary or consistorial court in Scotland. The offending wife loses her rank or title acquired by marriage; and the offending husband must return the dowry of his wife. The law of Scotland prohibits the offending parties from marrying. The marriage between such parties is permitted in England, unless, as we believe happens in some cases, a special enactment to the contrary be introduced into the act of parliament authorising the divorce.

The prevalence of this offence, for it is scarcely regarded as a crime, and the mitigation of the penalties annexed to it, form a striking feature in the manners of modern times, and might afford useful employment to the researches of the moralist and legislator in investigating its causes, and considering the means of its prevention. It would appear, at first sight, that those who have been guilty of deliberate seduction,—of embittering the sweets of domestic joy,—of entailing misery, not on one, but on several innocent families, could not be too severely punished. But, on the other hand, it is strenuously maintained, that excessive severity of punishment is not the surest and most effectual means for the prevention of crimes; and on this principle the penal practice of this country, in such cases, proceeds. The expression of public opinion in reprobating the guilt of adultery, is altogether disproportionate, in the estimation of the sober-minded and dispassionate, to the enormity of the offence. The female offender, it is true, is, in some degree, avoided by the virtuous of her own sex; but the male delinquent, in few instances, suffers any degradation in society: his honour, in the fashionable meaning of the term, has contracted no stain, and he is freely admitted and courteously treated in all polished circles.

ADVOCATE, a person who pleads or defends causes in courts of law. In England, the term *counsel*, or *barrister at law*, and in Ireland *counsellor*, is applied to persons of this profession; but *advocate* is the common appellation in Scotland. The members of the faculty of advocates have the exclusive privilege of pleading before the supreme civil and criminal courts in Scotland, as well as in every civil and ecclesiastical court. They enjoy the right also of pleading before the king in council, and the two houses of parliament. From this body, the judges of the supreme civil and criminal courts, and those of the court of exchequer, as well as the sheriffs of counties, which latter must be advocates of three years standing, are appointed. The faculty of advocates consists of nearly three hundred members, and possesses an excellent library, containing not fewer than 70,000 volumes. This library is entitled to a copy of every book entered in Stationer's Hall; and L.100 sterling of the admission-money of new members is appropriated to the purchase of books.

Candidates for the profession of an advocate undergo three trials. The first is an examination, which is conducted in the Latin language, of their knowledge of the Roman or civil law; the second examination, after the lapse of a year, refers to their knowledge of the law of Scotland; and in the third a Latin thesis is defended.

ADVOCATE, *Lord*, or *King's* advocate, one of the officers of state, and principal crown lawyer in Scotland. He is the public prosecutor before the Court of Justiciary, or supreme criminal court. The Lord Advocate has the power of determining, from the evidence of facts and circumstances laid before him, whether persons charged with crimes shall be prosecuted; and in crimes of a capital nature, he has the power of restricting the sentence to an arbitrary punishment, or a punishment at the discretion of the judge, which does not extend to death.

ADVOCATION, *Bill of*, in the law of Scotland, is a petition of appeal of a party in an action before an inferior court to the supreme court. Letters of advocation are the decree or warrant of the Court of Session, discharging the inferior court from further proceedings in the cause, and advocating it to itself.

ADVOWEE, anciently the advocate of a church, or religious house, who was the guardian and administrator of its temporal affairs. This office is said to have been first introduced about the fourth century; and persons of the highest rank were appointed to it, for the purpose of defending with arms, or of protecting with power and authority, the establishments to which they were nominated. The Emperor Charlemagne held the title of advowee of St Peter's; and the Pope constituted Edward the Confessor and his successors advowees of the monastery of Westminster, and of all the churches in England. Sub-advowees were sometimes appointed in monasteries as substitutes for the advowees.

ADVOWSON, is the right of presentation to a vacant benefice in England. An advowson is said to be presentative, when the patron presents a person to the bishop to be instituted in his church. It is called *collative*, when the benefice is given by the bishop as the original patron, or by means of an acquired right; and *donative*, when the patron, by a single donation in writing, grants possession, without presentation, institution, or induction. Advowson is equivalent to patronage in Scotland.

ÆACEA, were solemn festivals and games, which were celebrated in the island of Ægina, in honour of Æacus.

ÆACUS, the son of Jupiter and Ægina, and king of the island, named after his mother. According to fabulous history, after the island of Ægina was depopulated by a plague, the grief of Æacus drew forth the compassion of Jupiter, who converted all the ants into human beings, who were hence called *myrmidons*, from the Greek word which signifies an ant. But the story, divested of fable, is supposed to refer to Æacus, a wise and prudent prince, who roused the exertions of the inhabitants, to recover, by industry and commerce, the losses which they had sustained by the plunder of pirates. Æacus was so highly esteemed for his love of integrity and justice, that Pluto, the god of the infernal regions, appointed him one of the judges of the dead:—another moral lesson wrapped up in fable, which teaches that the practice of virtue will be honoured and rewarded hereafter.

ÆBUDÆ, or Hæbudæ, the ancient name of the Western Islands of Scotland. The more modern name Hebrides, is supposed to have originated from the conversion of the *u* into *ri*, by the inattention of some transcriber.

ÆDILE, a magistrate among the Romans, to whose superintendance almost the whole of the public police of the city was entrusted. Two ædiles were originally chosen from the plebeian order, to assist the tribunes of the people in their duties. The office of the ædiles, as the word, signifying a building, from which it is derived, imports, was to take care of, and superintend the city, its public buildings, roads, markets, weights and measures, prices and quality of provisions, the censorship and inspection of books, particularly of dramatical performances. They possessed also a certain jurisdiction in determining causes of an inferior nature. It was also a part of the duty of the ædiles to guard against any innovation in religious ceremonies; and to see that the ordinances of the people, and the decrees of the senate, were safely deposited in the temple of Ceres. The exhibition of public games, at their own expence, was also required from the same magistrates, which was attended with the ruin of many individuals who held that office. But when the senate had decreed, on the occasion of the differences between the patricians and plebeians being settled, that games should be celebrated in a splendid manner, in gratitude to the gods for this event, the ædiles declined to undertake the task, on account of the enormous expence. The patricians came forward, and offered to take charge of the festival, if they were admitted to the office. Two ædiles of the patrician order were then elected, about the year of Rome 388, and were called *ædiles curules;* because in the administration of justice they sat in a chair ornamented with ivory, while the plebeian ædiles sat on plain benches. Besides these four ædiles, Julius Cæsar created two others, who were distinguished by the name of *ædiles cereales;* because to their management and inspection were committed the public granaries, and all matters relative to corn.

ÆGÆ, or ÆGEA, or *Edessa,* the modern Vodina, was so called by Caranus, the first king of Macedonia, who had been directed by the oracle to establish his empire under the conduct of a flock of goats. He arrived in Macedonia during a storm, and pursuing a flock of goats, which ran to the city for shelter, he surprised and took it. He then changed the name to Ægea, derived from a word which signifies a goat; and hence, too, it is supposed, the he-goat, mentioned by the prophet Daniel, is the symbol of the kings of Macedon.

ÆGEAN SEA, is the ancient name of that part of the Mediterranean which separates Europe from Asia, and now called the Archipelago.

ÆGEUS, in fabulous history, was king of Athens, and the father of Theseus. The Athenians having put to death the son of Minos, king of Crete, Minos made war upon them, was victorious, and concluded a peace, with the severe condition of seven noble Athenian youths being annually chosen by lot, and sent to Crete, to be devoured by the Minotaur. On the fourth year, the lot fell on Theseus. The ship in which he departed was ordered to have black sails; and, in case of his death, it was to return with the same; but if he should be fortunately victorious, they were to be changed into white. Theseus killed the Minotaur, and returned, but neglected to change the sails; and the father, concluding that his son was dead, threw himself into the sea, and from this event it derived its name. Divine honours were decreed to Ægeus by the Athenians, who performed sacrifice to him as a sea god, the adopted son of Neptune.

ÆGINA, an island in the Saronic gulph, or bay of Engia, about 20 miles distant from Athens. Æacus changed its name from Œnopia to Ægina, in honour of his mother, who, according to the fable, was the daughter of Æsopus, king of Bœotia, was seduced by Jupiter, in the likeness of a lambent flame, and was carried from Epidaurus to this island, then a desert. The industry of the ancient inhabitants, in communicating fertility to a barren soil, obtained for them the name of *myrmidons*, or *ants*. They also applied themselves successfully to commerce, and are said to have been the first who coined money. They were rivals of the Athenians in naval power, and disputed the palm of victory with them at the celebrated naval engagement of Salamis. The remains of a magnificent temple, which was dedicated to Jupiter, and erected on a lofty mountain, at a distance from the sea, are still visible. Ægina fell under the power of different states of Greece at different periods. In 1536 it was conquered by the Turks; the capital was taken and burnt, and, after a dreadful massacre, the surviving inhabitants were reduced to slavery. Ægina produces corn, wine, olives, and almonds; and it abounds with pigeons and partridges. The latter are said to be so numerous, that the inhabitants, to avoid a famine, annually destroy their eggs.

ÆGINA, now called Engia, is the capital of Ægina, and only remarkable for a castle, which is capable of admitting about 800 troops, and thirteen churches, of mean appearance, some parts of which are supposed to be fragments of a temple of Venus.

The remains of temples, theatres, and public works, some of which are now under the surface of the water, afford ample proof of the ancient magnificence of this place.

ÆGIPHILA, Goat-friend, a genus of plants belonging to the class Tetrandria.

ÆGIS, a word signifying a she-goat, is the name of the shield of Jupiter and Minerva. Upon the death of the goat Amalthea, by which Jupiter was suckled, he covered his shield with its skin, and presented it to Minerva, and hence Minerva's shield was called *ægis*. Jupiter, according to the fable, restored the animal to life, covered it with a new skin, and placed it among the stars. Some antiquarians suppose that the ægis is not a shield, but a breastplate, as it is described by Virgil, Æneid, lib. viii. 435 and 354.

AEGOPODIUM, Goat-weed, or Goat's-foot, a genus of plants belonging to the class Pentandria.

ÆGOSPOTAMOS, the ancient name of a small river of the Thracian Chersonesus, which falls into the Hellespont. The road for ships near its mouth is famous, in ancient history, for a victory gained by the Lacedemonians under Lysander, over the Athenians under Conon. This complete overthrow was followed by the capture of Athens, the destruction of the naval power of the Athenians, and the termination of the Peloponnesian war.

ÆLIA CAPITOLINA, the name of the city built by the emperor Adrian, near the site of the ancient Jerusalem. In the year 134, when he visited the eastern parts of the Roman empire, the city being in ruins, he established a Roman colony in it, and dedicated the temple which he erected in place of that of Jerusalem, to Jupiter Capitolinus. To this was prefixed his own family name, which he gave to the city.

ÆLIAN CLAUDIUS, a learned Roman who was born at Præneste, in Italy, and flourished in the reign of the emperor Adrian. He was greatly distinguished as a Greek scholar, and was so perfect a master of that language that he could speak and write it with much facility and fluency. He was the author of numerous works on different subjects, the chief of which, *Various History*, and a *History of Animals*, in seventeen books, written in Greek, have been frequently quoted.

ÆNEAS, a celebrated Trojan prince, was the son of Anchises and Venus; Æneas and Antenor were the only persons among the Trojans who preferred peace to the long war which terminated in the destruction of Troy, and strongly urged that Helen, whose detention was the cause of the war, should be restored. This prudent counsel brought upon them the suspicion of treachery. When Troy fell into the hands of the Greeks, Æneas and his friends fought bravely against the assailants; and being overpowered by superior numbers, he escaped from the flames which raged in the city, carrying his aged parent, Anchises, on his shoulders, and leading his son Ascanius by the hand; but in his flight he lost his wife Creusa. Æneas and some of his surviving countrymen retired to mount Ida, built a fleet, set sail in search of a new settlement, and after many perilous adventures by sea and land, arrived at Sicily, where he lost his father. Driven by a storm to the coast of Africa, he was most hospitably entertained by Dido, queen of Carthage, who fell desperately in love with him, and solicited his acceptance of a share of the government of her kingdom. Rejecting her offer, he departed from Africa, landed in Italy, married Lavinia, the daughter of Latinus, king of the Aborigines, and built Lavinium, for the residence of his countrymen. But Turnus, king of the Rutuli, to whom Lavinia had been betrothed before the arrival of Æneas, being disappointed, and enraged at the preference given to a stranger, made war on Latinus and his new son-in-law. Latinus fell in battle, and the army of Turnus was routed. Æneas succeeded to the throne of Latium, and united both nations under the common name of Latins. Four years had only elapsed when Æneas was slain in battle with Mezentius, king of the Tuscans. The Romans trace their descent to Æneas; and after his death he was invoked as a god by the name of Jupiter Indiges.

ÆNEID, the name of Virgil's celebrated epic poem, which relates the adventures of Æneas and the Trojans, their establishment in Italy, and the foundation of the Roman empire. The Æneid is divided into twelve books, the first six of which are generally allowed to be the most interesting. It is said that the last six books were in an unfinished state, or, at least, had not received the last correction of the author at his death, and that he ordered the whole poem to be committed to the flames. Had the order been obeyed, polite literature would have sustained an irreparable loss. And whatever inferiority may be discovered by critics in the descriptions and characters of Virgil, when compared with the bolder and more striking beauties of Homer, of which they are obviously an imitation, the lovers of poetry must ever admire the Æneid on account of the correctness and elegance of its diction, and the smoothness and melody of its versification, as one of the most splendid and finished compositions.

ÆNIGMA, from a Greek word, which signifies to hint a thing darkly, is an obscure manner of expression, or representation, in which the words or figures employed convey a different meaning from their obvious and literal import. Exercises of this kind, from the prevalence of false taste, were at one time frequent among the learned; and, when alchemy flourished, the adepts described their processes in this ambiguous mode of expression, that their true nature might not be easily discovered.

ÆOLIAN HARP, or lyre, a musical instrument, from which the most delicate and agreeable tones are obtained by the impulse of the wind. For a description of this instrument see Acoustics.

ÆOLIAN ISLANDS, are seven islands which are situated between Sicily and Italy, and derive their name from Æolus, who is supposed to have reigned about the time of the Trojan war. They are now called *Lipari Islands*. See Lipari.

ÆOLIAN SEA, is part of the Ægean sea which washes the shores of Æolis, and is now called the gulph of Smyrna.

ÆOLIC, one of the five dialects of the Greek:

tongue, was first used in Bœotia, from whence it passed into Æolia. It approaches nearly to the Doric dialect.

ÆOLIPILE, signifying the ball of Æolus, is a hollow metallic ball, with a cylindrical pipe. When the ball is nearly filled with water, and the pipe screwed in, it is exposed to heat, and when the water boils, or is converted into steam, the steam rushes out with great violence and noise. When alcohol is introduced into a similar apparatus, a lower degree of heat converts it into vapour, the current of which is sometimes employed as a blowpipe.

ÆOLIS, or Æolia, a country of Asia Minor, which was formerly occupied by a colony of Greeks. According to some geographers, it now forms part of Anatolia.

ÆOLUS, a king of the Æolian islands, according to ancient history, succeeded his father-in-law in the government of these islands, and gave them his name. In the heathen mythology, Æolus is represented as the god of the winds, which he kept confined in a vast cavern; but the origin of the fable is said to be derived from the wisdom and prudence of Æolus, and from his skill in astronomy, and observing natural appearances, by which he could predict changes of weather, and the approach of storms. The Romans paid divine honours to Æolus, and he was considered as the son of Jupiter and Acesta.

ÆON, a word signifying an age, or certain period of duration, was employed by the Platonists to denote any virtue, attribute, or perfection; and hence the Deity was represented as an assemblage of all possible *æons.* This Platonic doctrine was introduced into the Christian faith in the first ages of the church, by different sects, and particularly by the Valentinians.

ÆRA, or era, a certain fixed point of time which is distinguished by some remarkable event, and to which both preceding and future events are referred. For example, the Christian æra, which commenced at the birth of Christ.

ÆRARIUS, a name given by the Romans to a citizen degraded on account of some offence. Persons of this description could not make a will, inherit property, vote in assemblies, or hold a place of emolument or honour; but while they were precluded from the privileges, they were still subjected to the taxes of the state.

AERIAL, in its general acceptation, signifies something which partakes of the nature and properties of air.

Aerial, *Perspective*, denotes the appearances of visible objects, as they are modified by distance, and varieties of light or shade; or, it is the art of imitating these appearances in painting. See Painting.

AERIFORM, a term expressive of something in the form or state of air; as the airs or gases, which are different from the common air of the atmosphere, are called in chemistry *aeriform fluids.*

AEROLITES, a word from the Greek, signifying air and stone, is applied to those mineral bodies which have fallen from the atmosphere, in which, according to some naturalists, they have been formed.

AERONAUT, a name applied to a person who sails through the air by means of a balloon.

AERONAUTICS, from two Greek words, signifying air, and the art of sailing, is the art of navigating the atmosphere with balloons.

AEROSTATION.

Aerostation, in its original meaning, signifies the pressure or equilibrium of the air; but, in a more general acceptation, it has been applied to the art of navigating the atmosphere by means of balloons.

Early History.—Those who are fond of retracing the progress of arts to remote antiquity, may probably think their researches rewarded with the discovery of the origin of aerial navigation, or, at least, of the first attempts at flying in the air, in the story of Dædalus, who, it is said, constructed wings for himself and his son; and, to escape the resentment of Minos, king of Crete, by whom they were kept in durance, flew from that island to Sardinia, and afterwards to Cumæ, in Italy. But, perhaps, the whole of this ancient fiction ought merely to be regarded as the expression of an ingenious invention, or an arduous enterprise, clothed in fable. Few nations, however, exist, among whom, even in the earliest times, certain vague notions have not prevailed of the practicability of traversing the air; but this power was generally ascribed to the agency of supernatural beings. Roger Bacon, an English monk, who died before the termination of the thirteenth century, seems to be the first who speculated on this arduous enterprise upon rational principles. He says, that a machine had been constructed for the purpose, and that the experiment had been successfully made by a person whom he knew. This machine is said to have consisted of two large hollow globes of thin copper, exhausted of air.

About the middle of the seventeenth century, John Wilkins, bishop of Chester, who had distinguished himself by his mathematical and physical learning, published a treatise, entitled "The Discovery of a New World;" in which he asserts, that it might be possible to reach the moon, if the earth's attraction were once overcome. He states also the general principle, that a vessel filled with lighter air, will float and rise in heavier air; but he refers particularly to mechanical contrivances for traversing the air, and thinks that a flying chariot might be constructed on mechanical principles.

Francis Lana, a Jesuit, who was contemporary with Bishop Wilkins, proposed a method of flying in the air, similar to that of Friar Bacon. His method was to construct four globular vessels of thin copper, each twenty feet in diameter, and these vessels being exhausted of air, would float in the atmosphere, and support a certain weight. But although the principle be correct, it could not be put in practice, as no vessel sufficiently thin to float in the air, could resist its pressure when exhausted.

In the year 1709, a singular and complicated flying machine was constructed by a Portuguese friar, of the name of Gusman. This machine was in the form of a bird, was furnished with tubes, through which the air passed, to fill its sails or wings, and, when the wind was deficient, by means of bellows concealed within its body, for the purpose of raising it in the air. Pieces of amber were fixed in the upper part of the machine, and magnets were inclosed within spheres, that its elevation might be assisted by electric and magnetic attraction. It does not appear, nor indeed is it probable, that this machine answered the purpose; but the inventor was rewarded with a liberal pension during his life. In the year 1736, it is said that Friar Gusman constructed a wicker basket, of seven or eight feet in diameter, which was covered with paper, and which rose about 200 feet in the air; and, it is added, that this effect was generally ascribed to witchcraft.

In the year 1755, Joseph Galien published a small treatise at Avignon in France, entitled, "The Art of Navigating the Air," in which he mentions, that a bag of cloth or leather, containing air lighter than that of the atmosphere, might be employed for the purpose of aerial navigation; but the knowledge, or means of preparing such an air, were not within the reach of the author.

The discovery of inflammable air, or hydrogen gas, by Mr Cavendish, in 1766, was the first approach to any successful attempts in aerial navigation; and Mr Cavallo was the first who made experiments with this air. But having tried bladders and Chinese paper, both of which failed, he succeeded only in blowing up with this air soap-bubbles, which rose rapidly to the ceiling, and burst, by striking against it. This experiment was made in the year 1782. In one account of the origin and early history of balloons, it is stated, that a similar experiment with bags of thin silk and paper, filled with hydrogen gas, was devised and attempted by the brothers Montgolfier, and that the bags thus prepared ascended rapidly to the ceiling; but, from the sudden escape of the gas, in a few seconds fell to the ground.

First Fire Balloon.—The brothers now alluded to, Stephen and Joseph Montgolfier, were proprietors of a paper manufactory near Annonay in France, and had particularly directed their attention to this subject, about the middle of the year 1782. The ascent of smoke and clouds in the atmosphere, seems first to have suggested the plan of including an artificial cloud in a large bag, of a thin and light material, which being specifically lighter than the air, would float in it. In the month of November of the same year, the experiment was made by Joseph Montgolfier at Avignon. He prepared a silk bag, of a parallelopiped form, and containing about forty cubic feet. Burning paper was applied to an aperture of its lower extremity, the internal air was rarified, and the bag expanding, rose rapidly to the ceiling of the apartment in which the experiment was made. A similar experiment was repeated in the open air, and the bag rose to the height of seventy feet. In another experiment, a bag of 650 cubic feet capacity was constructed, and when the air was rarified, it expanded, and burst from the ropes by which it was held, and reached an elevation of 600 feet.

On the 5th of June 1783, the first public exhibition of the ascent of a balloon took place at Annonay, in presence of an immense assembly of spectators. A bag of a globular form, constructed of linen, lined with paper, and having a capacity of more than 23,000 cubic feet, was found capable of raising 500 pounds, including its own weight. Chopped straw and wool were burnt under the aperture of the balloon. It immediately began to swell; and in five minutes, when it was fully expanded, its ascensive power could scarcely be counteracted by the united strength of eight men; and when it was liberated, it rose rapidly, amidst the enthusiastic acclamations of a countless multitude, to the height of a mile, was carried along by the current of wind, and, after being suspended in the air ten minutes, it fell to the ground a mile and a half distant from the place of ascent. This extraordinary exhibition made a strong impression on those who witnessed it; and as the news was circulated through Europe, various sentiments were excited; for, while the accuracy of the statement was doubted by some, the relation was altogether disbelieved by others.

First Balloon with hydrogen gas.—In August following, a subscription was set on foot at Paris, to defray the expense of an inflammable air balloon. Two brothers of the name of Robert, under the direction of M. Charles, a professor of experimental philosophy, constructed a balloon of thin silk, varnished with a solution of elastic gum. It was of a globular shape, about thirteen feet in diameter, and it was distended with hydrogen gas obtained from 1000 pounds weight of iron filings, and 500 pounds of sulphuric acid diluted with water, and conveyed into the bag through leaden tubes. But as this was the first attempt at the preparation of so large a quantity of hydrogen gas, from their inexperience in the proper manipulations, several days elapsed before it was filled; and as the gas was introduced into the bag without having passed through water, the heat and fumes of sulphurous acid with which it was impregnated greatly injured the silk. The distension was at last completed, and it rose to an elevation of 100 feet, where it was kept suspended; but as the public exhibition of its ascent was not to take place till next day, it was conveyed at the still hour of midnight, by torch light, and under a military escort, to the Champ de Mars, two miles distant. The day following, which was the 27th August 1783, an immense multitude of spectators assembled from all quarters, and covered every accessible spot, to witness a spectacle so new and unexpected. In the afternoon, the discharge of a cannon announced the completion of the preparations; and when loosened from the ropes, it instantly rose; and its rapid ascent to the height of 3000 feet was followed by one universal burst of acclamation from the astonished multitude. It passed through a mass of clouds, reappeared at a greater elevation, was again lost to view in another cloudy region; and having floated in the air for three quarters of an hour, fell in a field at the distance of fifteen miles from the place of ascent. A rent was observed in its upper part by the peasants who took it up; and to this the fall was ascribed.

Fire Balloon ascends from Versailles—Invited by the Royal Academy of Sciences to exhibit the experiment in their presence, and at their expense, Joseph Montgolfier arrived in Paris about the beginning of September of the same year, and constructed a balloon of coarse linen, lined with paper. It was of an oval form, 75 feet in height, and 43 feet wide; was fully inflated in ten minutes, by burning 50 pounds of chopped straw and 12 pounds of wool, and was found capable of raising 500 pounds from the ground. The succeeding day was fixed for the public exhibition; but a stormy night intervening, entirely demolished the machine; and it required five days to replace it with another, which was painted and ornamented with various figures and devices. On the morning of the 19th of September, it was brought forward and placed upon a scaffold, in front of the palace of Versailles; and, in a short time, every place from which the ascent was expected to be seen was crowded with an immense multitude of spectators of every rank and description, not only from the capital, but also from the surrounding country. After the royal family and their suite had examined the apparatus, the discharge of a mortar announced the commencement of inflating the balloon. In ten minutes it was completely filled; and a basket, in which were placed a sheep, a duck, and a cock, was attached to it. Another discharge of the mortar was the signal of cutting the ropes, when it ascended with a majestic motion, and somewhat in an oblique direction, to the height of 1500 feet. At that point it seemed for a short time stationary; and after being eight minutes in the air, fell to the ground at the distance of two miles. The animals, the first carried through the air by this new vehicle, escaped uninjured, and the sheep, when found, was quietly feeding.

De Rozier the first aeronaut.—Another balloon, nearly of the same dimensions, was afterwards prepared, of a stronger and better construction, by M. Montgolfier; and Pilatre de Rozier, an enterprising young naturalist, offered himself to be the first aerial adventurer. When the balloon was inflated, and the car attached, de Rozier placed himself in it, and it rose to an elevation of 300 feet, as high as it was permitted by the length of the ropes by which it was held. It remained suspended for a few minutes at this height, and with a gentle motion returned to the ground. Similar experiments were repeated by the same naturalist; and during his descent in one of them, the balloon fell among some trees, in the branches of which it was entangled; but by feeding the fire with fuel, he dexterously extricated himself, rose to a greater height, and at last descended in a more commodious spot.

The successful issue of these experiments shewed that the dangers of navigating the air, by machines of this description, were of a less formidable nature than was at first apprehended, and that the aeronaut possessed the means of rising in the atmosphere, by supplying the balloon with rarified air, and throwing out ballast, and also of descending, by allowing the air within the machine to cool and be condensed; and afforded sufficient encouragement to bolder and more arduous attempts. It was justly supposed, too, that the balloon being held down by cords, subjected it to irregular motions, and thus exposed the voyager to serious accidents. With all this in view, an aerial voyage was determined on, in which the machine should be at full liberty, or left to the guidance of the navigators. And here the adventurous Pilatre de Rozier presented himself to undertake the arduous task.

First aerial voyage.—The 21st of November 1783 was the day fixed for this grand experiment. The weather was unfavourable; and the balloon was nearly destroyed by the violence of the wind; but in two hours, by the activity of the workmen, the injury was repaired; and the preparations being completed, De Rozier and the Marquis d'Arlandes, who accompanied him, seated themselves in the car, which was also furnished with ballast and materials for fuel. The weight of the whole apparatus was estimated at 1600 pounds. At two o'clock the balloon was liberated, and its majestic ascent excited the varying emotions of anxiety, wonder, and amazement, from the astonished spectators; and when the adventurers, soaring aloft, waved their hats, the salutation was returned with a general burst of acclamation from the admiring multitude. The balloon rose to the height of 3000 feet; was visible to the inhabitants of Paris during the greatest part of the voyage; and having traversed a space of more than five miles in 25 minutes, it descended safely to the earth.

The happy termination of this daring expedition could scarcely fail to excite feelings of the deepest interest. All who witnessed the exhibition were gratified with a most impressive spectacle; but the philosopher hailed it as the era of a new acquisition to the power of man. He had long beheld him familiar with the bold enterprise of penetrating the depths of the ocean; and now he could contemplate the same adventurous spirit in pursuing his excursive flights through the regions of the air. But those who saw and described this extraordinary scene, were not restrained by such sober reflections. The volatile fancy of the Parisians magnified the fleeting shadow of the balloon on the towers of a lofty edifice of the city into the exact representation of a total eclipse of the sun! And a historian of the same expedition, after the lapse of more than 30 years, indulging in the reveries of a heated imagination, has discovered an apt illustration of this aerostatic voyage, in the flight of the arch-fiend from Milton's infernal abodes; and the French aeronauts, like the Satan of that sublime poet, are uplifted "*in the surging smoke!*"

But, amidst the general exultation which pervaded all ranks of the French nation, a more substantial remuneration than empty applause awaited the brothers Montgolfier. The Academy of Sciences bestowed upon them the annual prize of 600 livres; the elder brother was raised to the rank of nobility; and the younger, while he was rewarded with a pension, had 40,000 livres placed at his disposal to support the expence of farther experiments.

Second voyage.—A keen rivalship now arose between the partizans of aerial navigation by means of rarified air, and those who preferred the method of filling balloons with hydrogen gas. The complete success of the late experiment gave a considerable preponderance in public estimation to the first system; but those who opposed it, confident of the superior advantages and ultimate result of their own method, determined to bring the matter to a practical test. The undertaking was entrusted to M. Charles and the brothers Robert; and the expence of the exhibition, which amounted to L.400, was defrayed by subscription. A balloon, of a spherical form, and 28 feet in diameter, was constructed of thin silk, or tiffany, varnished with a solution of elastic gum. A net was stretched over the upper hemisphere, and was fastened to a hoop, or band, which surrounded the middle of the balloon; and, a few feet under it, a car, for the reception of the voyagers, was suspended by ropes attached to the hoop. The car, constructed of wicker work, which was covered with painted linen, elegantly ornamented, was eight feet in length, four feet in breadth, and three and a half in depth. A valve was placed in the upper part of the balloon to permit the free escape of the gas; and a long silken tube was attached to its lower part, by which the balloon was to be filled. Various difficulties retarded the exhibition till the 1st of December 1783; when the balloon, and the apparatus for the preparation of the gas, were brought to a spot near the Thuilleries, which was chosen as the place of ascent. The materials employed in the production of the hydrogen gas, were diluted sulphuric acid and iron turnings. They were introduced into several wooden casks, arranged round a large cistern of water, in which was inverted a vessel for the reception of the gas, which, having previously passed through the water, was conveyed by leaden pipes to the balloon. The weight of the whole machine, including the ballast and travellers, amounted to 640 pounds; and, by calculation, it was found, that the air with which the balloon was distended was only $5\frac{1}{4}$ times lighter than atmospheric air.

It was near two o'clock before the preparations were fully completed. Messrs Charles and Robert then seated themselves in the car; and the balloon being unloosened, rose with a slow and steady motion. In the enthusiastic description of the narrator, it ascended "amidst profound silence and admiration, and permitted the spectators, of which the number was immense, to follow with their eyes and hearts two interesting men, who, like demigods, sought the abode of immortals, to receive the reward of intelligence, and carry the imperishable name of Montgolfier." The balloon soon reached the height of 2000 feet; and, by discharging a quantity of ballast, or opening the valve to allow the air to escape, they rose or descended at pleasure; but during the whole excursion, which continued for an hour and three quarters, they kept pretty nearly at the same height from the earth. At last they resolved to terminate their excursion, and they alighted safely, at the distance of 27 miles from Paris.

But although the balloon had become flaccid by the expenditure of air, when the voyagers dismounted from the car, it appeared still to possess a considerable ascensive power. This determined M. Charles to attempt alone another voyage. The machine being lightened 130 pounds, by M. Robert leaving the car, it ascended with such velocity, that, in ten minutes, it reached an elevation of 9000 feet. At this height, every object on earth disappeared from his view. When he left the earth, the sun had just set; but as he rose in the atmosphere, that luminary became again visible; and he had an opportunity of watching his parting rays as he sunk a second time below the horizon. An impressive scene now presented itself: vapours ascending from the earth, collected into clouds, of various fantastic forms; and the pale light of the moon, which had just risen, communicated a thousand varying hues. At this time he observed the balloon having a whirling motion, and, by the effect of a contrary current of air, returning in an opposite direction; and when the progress was horizontal, he was surprised at seeing the streamers of his banners pointed upwards,—an effect which must have been produced by an ascending current of air. When the balloon first rose, the thermometer stood at 41°, but at its greatest elevation it sunk to 21°. This great change of temperature produced considerable inconvenience; his fingers were benumbed with cold, and he experienced a violent pain in the jaw and ear of one side. During the higher part of his ascent, the balloon was greatly distended, and, to avoid the danger of bursting, he frequently opened the valve, when the air escaped with a rushing noise, and, being of a higher temperature than the air of the atmosphere, diffused a considerable warmth around; but the approach of night, and the recollection of the promise to his friends of returning in half an hour, warned him to discontinue his excursion. He therefore opened the valve, and descended slowly. The discharge of a few pounds of ballast within 200 feet of the earth, rendered the balloon nearly stationary; and having performed, in 35 minutes, a circuitous course of nine miles, he alighted safely in a field, at the distance of three miles from the place of ascent.

Third voyage.—On the 19th of January 1784, Joseph Montgolfier, Pilatre de Rozier, and four other persons, ascended from Lyons in the largest balloon which has yet been constructed. This balloon was of an oval form, above 130 feet in height, and 105 feet in width; it was formed of a double fold of linen, having three intermediate layers of paper. The expence of this exhibition, which amounted to L.180 Sterling, was defrayed by subscription. This immense balloon, when distended with rarified air, had so great an ascensive power, that it required the strength of 50 men to retain it. In seventeen minutes it was sufficiently dilated by the combustion of 550 lbs. of alder faggots; and the six adventurers having placed themselves in the car, it rose into the atmosphere, and continued for more than half an hour over the city; but having observed a large rent in the upper part of the balloon, they found it necessary to return to the earth, which they reached without sustaining any injury.

Blanchard's voyage.—M. Blanchard, who was distinguished afterwards by his aerostatic excursions, and who had long occupied his ingenuity in mechanical contrivances for the purposes of flying in the air, now contemplated the successful application of the same principles in the direction of balloons. In his first attempt on the 2d of March, from Paris, with a balloon filled with hydrogen gas, through the officious interference of a person who insisted on being the companion of his voyage the apparatus was injured, and the balloon, after rising a few feet, returned to the earth with a severe shock. The curiosity of the intrusive stranger was now fully gratified, and he resigned the entire possession of the car to Blanchard, who ascended alone, and rose rapidly to an elevation of more than a mile; and after a voyage of an hour and three quarters, in different currents of air, he descended safely to the earth. But it did not appear that he derived any other advantage from his apparatus of oars and rudder than being able to communicate a whirling motion to the balloon.

Guyton-Morveau's ascension.—In the month of April the same year, M. Guyton-Morveau, celebrated for his chemical researches, and the Abbe Bertrand, ascended from Dijon, with a balloon constructed of varnished silk, and filled with hydrogen gas. The balloon was of a spherical form, 29 feet in diameter, and was furnished with an apparatus for the purpose of directing its course, It was launched at five o'clock in the evening, and soon rose to the height of more than 10,000 feet, where the cold was pretty intense. In this lofty situation, they beheld an extensive ocean of clouds floating below them, and enjoyed the splendid spectacle of a parhelion, or mock sun, composed of numerous concentric circles of varied hues; and having continued their excursion for an hour and a half, they returned safely to the earth, at the distance of 18 miles from Dijon. In their attempts to steer or direct the course of the balloon, they were not more successful than Blanchard. The same chemist, accompanied by another person, ascended with the same balloon on the 12th of June, at seven in the morning. They reached the height of 6,000 feet, and alighted 12 miles from Dijon.

Voyage of the Duke of Orleans.—A similar attempt was made in directing the course of a balloon, in the construction of one by the brothers Robert, at the expence of the Duke de Chartres, and afterwards better known as the Duke of Orleans. This balloon was 56 feet in height, and 36 in diameter; and it was supposed that this form would render it more manageable, at the pleasure of the voyagers. It was also furnished with oars and a rudder; and, besides, a small balloon was introduced, for the purpose of being filled, by means of bellows, with common air. The object of this small balloon was to supply the means of descent, without the expenditure of the hydrogen gas, with which the large balloon was filled. On the 19th of September, when the preparations were completed, the Duke of Orleans, the two brothers, and a fourth person, placed themselves in the car, which was also loaded with 500 pounds of ballast. The balloon rose slowly; and when they had reached the height of 1400 feet, the aeronauts were in no small degree alarmed at the gloomy appearance of thick clouds rolling along the horizon, and indicating the near approach of a thunder-storm. Some distant peals of thunder were heard, and they were driven about for some time by a whirlwind. A sudden change of temperature, of not less than 16°, produced a rapid descent of the balloon, which at one time was only about 250 feet from the tops of the trees of a forest; but the discharge of 40 pounds of ballast instantly reversed its progress, and it soon ascended to the height of 6,000 feet. A sublime scene now presented itself. A wide ocean of clouds, exhibiting every fantastic shape, extended below them, and seemed to preclude their return to the earth, while the balloon continued to be greatly agitated. In the alarm excited by their perilous situation, the cords by which the interior balloon was suspended, were cut, and it fell upon the aperture for the escape of the gas from the large balloon, and shut it up closely. Ascending higher, they surmounted the stormy region, and the sun, unobscured by a cloud, shone full upon them. But the influence of his rays produced such an expansion of the hydrogen gas, that they were every moment apprehensive of a rupture of the balloon. To permit the escape of the inflammable air, the Duke of Orleans pierced the lower part of the balloon in several places with his sword. The descent now was extremely rapid, and they narrowly escaped falling into a lake, by quickly discharging a considerable quantity of ballast; but after an excursion of five hours, and having traversed a space of 150 miles, they reached the earth in safety. In this voyage, a remarkable difference in the temperature of the external air, and of the air within the balloon, was observed. The hydrogen gas was at 104°, while the air of the atmosphere was only 63°.

First Female aerial voyager.—A fire balloon, or *Montgolfier*, as aerostatic machines on this principle were sometimes denominated, of an oval form, and 75 feet high, was constructed at Lyons, and ascended on the 28th of June 1784, in presence of the King of Sweden, who was then travelling in France. The adventurous aeronauts were Madame Thiblé, the first female who attempted such a voyage, and M. Fleurant. The balloon rose with such velocity, that in six minutes the objects on the earth were scarcely visible; its utmost elevation exceeded 13,000 feet; and having traversed six miles in three quarters of an hour, they alighted safely on the earth. The falling of a flag with its staff, of 14 pounds weight, affords some notion of the great height which they had reached; for it required seven minutes from the time of being projected from the car till it reached the ground. In this voyage, the different currents of air, in different regions of the atmosphere, were distinctly perceptible; and when the balloon passed from one current to another, it acquired an irregular or undulatory motion. In the succeeding month of July, another large fire balloon was constructed by order of the French king, and ascended from Versailles in presence of the Swedish monarch. De Rozier and Proust were the enterprising voyagers. They soon rose to the height of more than 12,000 feet, and were involved in an ocean of white clouds. The thermometer sunk to 25°; and, at this temperature, as might be expected, they were covered with a thick shower of snow, while it rained on the earth. Leaving these wintry regions, they descended to contemplate the more agreeable scenes of the verdure and luxuriance of summer; and, after an hour's excursion, alighted safely at the distance of 26 miles from Versailles.

Aerostation.

First Balloon in England.—The exhibition of balloons was not now confined to France, but, long before the period to which our narrative reaches, had extended over the greater part of Europe. Count Zambeccari, an Italian, sent up the first balloon in England, nearly a year after the earliest attempts had been made in France. This balloon was of a spherical form, ten feet in diameter, and was constructed of oiled silk; and being all over finely gilded, it presented, on its full expansion, the attractive appearance of a golden ball floating in the air. It was filled with hydrogen gas at one o'clock on the 25th of November 1783; it ascended from the artillery ground in London, in presence of an immense multitude of spectators, and having remained in the atmosphere for the space of two hours and a half, it came to the earth, in Sussex, at the distance of 48 miles. In December of the same year, Mr Sadler constructed a balloon, which was filled with hydrogen gas, and sent up from Oxford; and, in the summer following, the same aeronaut prepared another balloon, which was 18 feet in diameter, was filled with hydrogen gas, and was sent up from the same place with a dog. The balloon burst in the air, but the animal came to the ground unhurt, at the distance of a quarter of a mile.

First aerial voyage in Britain.—Beside those which we have noticed, other experiments of a similar description were made in different parts of this country. But the first aerial voyage in Britain was performed by Lunardi, an Italian, who ascended from London on the 21st of September 1784. The balloon which he employed on this occasion was constructed of alternate stripes of red and blue oiled silk. It was 33 feet in diameter, of a pear shape, and was filled with hydrogen gas. The same active adventurer repeated the experiment in various parts of England; and in the succeeding year he ascended in Scotland; and he was the first person who gratified the inhabitants of Glasgow and Edinburgh with the interesting spectacle of an aerial excursion.

Aerial voyage across the English Channel.—Blanchard, whose ascension with a balloon from Paris, and his contrivances for directing its course, have been already noticed, had arrived in England for the purpose of exhibiting similar experiments. His most adventurous excursion from Dover to Calais was accomplished on the 7th of January 1785. In this voyage he was accompanied by Dr Jeffries, an American gentleman. The morning was clear and frosty, and the wind, which was scarcely perceptible, was from N. N. W. The preparations for filling the balloon with hydrogen gas commenced at ten o'clock; and in two hours and a half it was thought to be sufficiently distended for the voyage. At one o'clock, M. Blanchard and his companion being seated in the car, it was pushed off from Dover Cliff; and they were no sooner launched into the air than they found it necessary to discharge a considerable portion of their ballast. The balloon then rose with a slow and gentle motion, and afforded them a charming prospect of the southern coast of England. But their progress towards the French coast was greatly retarded by the stillness of the air. Having passed over several vessels, and after being nearly an hour in the atmosphere, the balloon began to descend, which required a fresh portion of ballast to be discharged; and, as the descent still continued with accelerated velocity, the whole was thrown out; but as this had no effect in retarding their progress towards the water, they threw out a parcel of books. This produced a temporary ascent; and they were now midway between England and France. In a short time, the balloon began again to descend, when the remainder of their books and provisions, and every thing that could be spared, were thrown out. A bottle, in its descent, emitted, with a rushing sound, a steam like smoke, and when it struck the water the shock was perceptibly felt on the car and balloon. The ascensive power of the balloon was now so greatly diminished, that all this loss of weight was insufficient to counteract its descent; they therefore parted with their anchors and ropes, and having stript off their clothes, they secured themselves with slings, with the intention of cutting away the car. But they had now the satisfaction to observe the balloon rising and approaching the French coast; and, as they passed over the high land between Cape Blanc and Calais, it attained a greater elevation than in any part of their course. After a perilous voyage of nearly three hours, they descended safely on a vacant spot in the forest of Guiennes, not far distant from Calais, where they experienced the kindest and most hospitable reception.

Disastrous fate of De Rozier and Romaine.—It seems to have been a considerable object of attention with the French naturalists, to construct aerostatic machines in such a manner as to give the aeronaut the power of remaining in the atmosphere, or of descending at pleasure, without the expenditure of the hydrogen gas, or of the necessary ballast. The introduction of a small balloon filled with common air, had been tried, and failed. A combination of the principles of the two kinds of balloons was now proposed, and the plan was unfortunately executed by the adventurous Pilatre de Rozier. It seems probable, too, that the perilous voyage of Blanchard and his companion might have led to the adoption of the contrivance, which, in the end, proved fatal to the voyagers. The aerial excursion which, on this occasion, was projected by De Rozier, was to cross the channel from France to England. For this purpose, two balloons were employed; one of them, about 37 feet in diameter, was filled with hydrogen gas, and the other, which was distended with rarified air, had an ascensive power equal to 60 pounds. The fire balloon was suspended below the other, and at such a distance as to remove every apprehension of danger from the fire; but a short time only had elapsed after their ascent, when the spectators perceived, not without anxiety, the upper balloon, which was filled with hydrogen gas, rapidly distending, while the aeronauts were observed pulling the valve, and making other exertions to allow the hydrogen gas to escape. Soon after, the whole apparatus appeared to be on fire; no explosion was heard, and the fire balloon continued for about a minute expanded; it then suddenly collapsed, and the remains of the machine descended from the height of three quarters of a mile,

Aerostation.

and fell to the ground, with the unfortunate travellers, who were killed on the spot.

Aerial voyage of M. Testu.—The aerial excursion of M. Testu, for the time which he continued floating in the atmosphere, a period of twelve hours, is unequalled in the history of aerostation. With a balloon 28 feet in diameter, filled five-sixths with hydrogen gas, and fitted with wings and other apparatus for steering, he ascended from Paris, at four o'clock in the afternoon of the 18th June 1786. The day was cloudy, and there was some appearance of rain. When the balloon attained the elevation of nearly 3000 feet, it became so much distended as to excite in the voyager considerable apprehensions of a rupture; and as he was anxious not to lose any part of its ascensive power by an expenditure of the gas, he made great exertions with his mechanical machinery to reach a lower region. His efforts were successful, and he descended safely in the middle of a corn field, in the plain of Montmorency. All who witnessed the descent of so unexpected a visitor, ran eagerly to the spot; and the possessor of the field, exasperated at the injury which his crop had suffered by the crowd whom curiosity had collected around the aerial traveller, actually seized him, and demanded indemnification. M. Testu quietly submitted, and persuaded the angry peasant that, having lost his wings, he was deprived of the means of escape. A number of persons seized the ropes of the balloon, and, as it floated at the height of twenty feet from the ground, dragged it through the air towards the village. But as this extraordinary prisoner was conducted in triumphal procession, he perceived that his machine had acquired additional buoyant power by the loss of weight; he cut the cord, and instantly soared aloft, leaving the disappointed peasants in silent amazement fixed to the spot, and in a few minutes, dashing into a mass of clouds, eluded their astonished gaze. Here the temperature was at the freezing point; for he observed icy particles floating around, while the thunder rolled at a distance below him. As the day declined, the balloon began to descend, and a little before seven o'clock it had nearly reached the ground; but the discharge of a quantity of ballast enabled it to regain its ascensive power, and in twelve minutes it was at an elevation of 2400 feet, when the thermometer indicated a temperature of 66°. The blast of a horn here attracted his attention; and seeing a party of huntsmen keenly engaged in the chace, he allowed some gas to escape, and about eight o'clock descended towards the place. Having resigned his wings as a useless encumbrance, and collected some stones for ballast, this enterprising adventurer ascended a third time, and was soon involved in a thick mass of clouds loaded with electric matter. The thermometer fell to 25°; but when he reached an elevation of 3000 feet, it rose to 66°. From this lofty station he beheld, between nine and ten o'clock, the sun sinking below the western horizon, and soon after the shades of night closed around. Shrouded in darkness, he was wafted about for the space of three hours in the gloomy region of the gathering storm. All the terrors which surrounded him, the lightning's flash, and the roar of the thunder, accompanied with copious showers of sleet and snow, did not for a moment damp his courage, or induce him to abandon his perilous situation:

> Unusual darkness broods; and growing, gains
> The full possession of the sky, surcharg'd
> With wrathful vapour, from the secret beds,
> Where sleep the mineral generations, drawn.
> Thence nitre, sulphur, and the fiery spume
> Of fat bitumen, steaming on the day,
> With various tinctur'd trains of latent flame,
> Pollute the sky, and, in yon baleful cloud,
> A reddening gloom, a magazine of fate,
> Ferment: till, by the touch ethereal rous'd,
> The dash of clouds, or irritating war
> Of fighting winds,————————
> They furious spring. THOMSON.

By means of an artificial light which he struck, he observed that the thermometer had sunk to 25°. The different kinds of electricity were indicated by a sharp iron point fixed on the car; a luminous spot sometimes rested on the point, denoting the electricity to be negative; and sometimes a pencil of rays, or stream of light, seemed to issue from it, marking its character to be positive. A flag, embellished with ornaments in gold, frequently sparkled with fire, and was at last torn by the lightning; the clothes and apparatus of the aeronaut, when he returned to the earth, emitted a sulphureous smell, shewing that he had been immersed in a torrent of electric matter; and, during the storm, the balloon seemed to be agitated with a kind of undulatory motion, in a perpendicular direction, arising, it might be supposed, from the sudden collision of adverse clouds.

At length this tremendous scene of awful sublimity closed; the "war of elements" ceased; the vapours dispersed, and the stars appeared:

> As from the face of heaven the shattered clouds
> Tumultuous rove, th' interminable sky
> Sublimer swells, and o'er the world expands
> A purer azure. THOMSON.

Having escaped the dangers of the storm, the intrepid voyager began to feel the cravings of hunger, and now indulged in a solitary repast. Between two and three o'clock, the ruddy streaks of light in the east announced the approach of day. A little before four he contemplated from his lofty station the rising of the sun; and his ballast being exhausted, he retreated from the airy regions, which he had occupied for twelve hours: he descended in safety near the village of Campremi, 70 miles distant from Paris.

Curious Incident.—Among the numerous aerial excursions performed by Blanchard, by which, it is said, that enterprising voyager amassed a considerable fortune, his ascent from Strasburgh, in August 1787, was attended by a curious incident. In this voyage, an experiment with the parachute was proposed, and for this purpose he took a dog with him. When he had attained an elevation of 6000 feet, the parachute, with the dog in a basket suspended from it, was detached from the balloon. Soon after its separation it was carried upwards by a whirlwind, and disappeared among the clouds. Some-

Aerostation. time afterwards Blanchard fell in with the parachute, still floating in the air, and the dog, in hopes of rejoining his master, began to express his satisfaction by barking; but when the aeronaut attempted to lay hold of it, a sudden gust of wind carried it far beyond his reach. Blanchard continued his voyage, and having passed over the city of Zell, descended safely to the earth; but it was not till after the lapse of twelve minutes from the time of his descent, that the dog and parachute reached the ground.

Garnerin's aerial voyages.—M. Garnerin, whose aerostatic exhibitions, whether in number or perilous adventures, have been exceeded by none, undertook an aerial excursion from Paris in October 1797, for the purpose of descending with a parachute detached from the balloon. The parachute, half expanded, was placed between the car and balloon, and formed a kind of canopy. When he attained an elevation of 2000 feet, the parachute was separated along with the aeronaut: its descent was slow and steady, while it gradually unfolded; but when it had reached its utmost expansion, it assumed an oscillating, and somewhat of a circular motion, during which M. Garnerin was not altogether free from serious apprehension of being thrown out of the car. As it approached the earth, the motion became more steady and vertical, and he at last descended in safety.

The same aeronaut visited England in 1802; and on 28th June of that year, accompanied by an English gentleman, ascended with a balloon of 20 feet diameter, from Ranelagh Gardens. They passed over London, rose to the heighth of 10,000 feet, and having traversed the space of 60 miles from the place of ascent, they alighted on a common near Colchester, having sustained some injury from the violence of the wind. The weather during this voyage was unsettled and stormy: in their ascent the adventurers passed through a mass of dense black clouds, where the thermometer sunk 15 degrees lower than at the surface of the earth. When they attained a greater elevation, the temperature became perceptibly milder; and in their descent through a similar cloudy region, the balloon was much agitated and tossed about by conflicting currents of air.

Accompanied by another person, M. Garnerin encountered another heavy gale, in an aerial excursion on the 4th of the following July. In this voyage he rose to the heighth of nearly 8000 feet in the space of fifteen minutes; and the balloon in its descent, at the distance of nine miles, came down with such velocity, that when it struck the earth it rebounded nearly 200 feet above the surface.

In the month of September of the same year, this enterprising adventurer ascended from London about six o'clock in the afternoon, during clear and serene weather, for the purpose of exhibiting his experiment of a descent with the parachute. When he had reached an elevation of about 8000 feet in the space of eight minutes, the parachute was detached, and the circumstances which attended his progress downwards were nearly similar to those already related in a former experiment. For half a minute the descent was extremely rapid, but when the parachute was fully expanded, the motion became gentle and slower. Soon after, the oscillation commencing, increased to such a degree as to render his situation for some time most perilous; but as it approached the earth it descended with a more steady motion, and he at last alighted without sustaining any injury. Aerostation.

Zambeccari's voyage.—Count Zambeccari, who exhibited the first balloon in England, undertook a perilous aerial excursion from Bologna, in October 1803. The companions of his voyage were Dr Grassetti and Signor Andreoli. The preparations were not completed before midnight; and although the aeronauts expressed a wish to delay their ascent till next morning, the outrageous clamours of the disappointed spectators counteracted their intention, and obliged them to proceed on their voyage. The balloon rose with great rapidity, and very soon floated in a region where the cold was so intense that the Count and the Doctor were overpowered, and fell into a profound sleep. Between two and three o'clock the balloon began to descend, and Signor Andreoli, who had resisted the lethargic propensity, seeing the threatened danger, roused his unconscious companions, which he had scarcely accomplished when they were precipitated into the sea. To extricate themselves the whole of their ballast, and every thing that could be spared, were instantly discharged; and the machine, thus lightened, again rose into the atmosphere, and carried them through a mass of clouds, where the cold condensed the vapour, and covered their clothes with hoar-frost. Half an hour only elapsed, when the balloon descending, was driven by a severe squall towards the coast of Istria, and almost across the Adriatic sea. The ascensive power of the machine was now so much exhausted, that they remained on the surface of the sea for nearly five hours, with little hope of being rescued from a watery grave. But at eight o'clock in the morning, when at the distance of twenty miles from the coast, the crew of a vessel, perceiving their perilous situation, with considerable exertion took them on board.

Another aerial voyage from Bologna, attended with still more formidable dangers, was undertaken by Count Zambeccari and Signor Andreoli, in the month of August in the following year. The ascent took place at ten o'clock in the forenoon; in three hours afterwards, when the voyagers were six miles distant from Bologna, they attempted to descend; but the anchor being entangled in a tree, deranged their apparatus, and overturned a spirit of wine lamp in the car; the spirit was set on fire, and the flames communicating to a large quantity of the same spirit in another vessel, spread to the clothes of the adventurers, who were instantly in a blaze, and threatened with immediate destruction. The Count was fortunate in extinguishing the flames; his companion retreated from the car, by sliding down to the tree by the anchor rope; and the balloon lightened, rapidly mounted into the air, and was soon lost in the clouds. Driven by the wind towards the Adriatic, the balloon descended to the sea, twenty-five miles from the shore, and the half-burnt car sunk into the water, while the aeronaut seized the ropes of the balloon, and secured himself by fastening one of them round his body. A number of fishing boats, whose crews had descried the balloon, approached; but some of them, struck with so unusual a sight, took it for a monster of the deep, and fled for safety; others, with more courage and humanity, exerted themselves, and succeeded in delivering the sinking adventurer from his perilous situation, after he had been four hours in the water.

Robertson's voyage.—On the 30th June 1803, Professors Robertson and Sacharoff ascended from Petersburgh with a balloon of thirty feet in diameter. The weight of the whole machine, including the travellers, exceeded 700 pounds. The balloon was launched about seven o'clock in the evening, mounted slowly, and passing over the course of the Neva, began to descend, when, on the discharge of a quantity of ballast, it rose again. In this excursion, a kind of log, constructed of two sheets of thin paper, suspended by a thread, was employed for the purpose of observing the sudden rising and falling of the balloon, with more precision than is indicated by the barometer; and, to view objects on the surface of the earth, a telescope was fitted in the bottom of the car. During a calm, which continued for a short time, the motion of the balloon was altogether imperceptible; but several times it assumed a rotatory motion. As this aerial excursion was projected for scientific purposes, the adventurers intended to prolong it through the night; but being uncertain to what point they were now carried, and seeing the whole of their ballast expended, they were compelled to return to the earth; and before eleven o'clock, after being nearly four hours in the air, they alighted safely, at the distance of forty miles from Petersburgh.

Voyage of Gay-Lussac, &c.—With a similar end in view, M. M. Gay-Lussac and Biot, two French naturalists, ascended from Paris in August 1804. They were furnished with instruments for observing the temperature, pressure, and moisture of the air. They first passed through a region of clouds composed of light fogs, in which the hygrometer indicated a slight degree of humidity; but reaching a greater elevation, the air became drier; and when they looked downwards, the floating vapours presented the same blueish tint as when they are seen from the earth. In the course of this voyage, as had been observed by others, the balloon occasionally assumed a rotatory motion, differing in the direction. After ascending to the height of more than 13,000 feet, they returned in safety to the earth, nearly fifty miles distant from Paris.

In September following, M. Gay-Lussac ascended alone; and when he had reached the height of 22,965 feet, he beheld, with astonishment, a mass of clouds floating at a still greater elevation. In his former expedition, the clouds were not higher than 5000 feet. He now mounted to a greater height, and at one time was not less than 23,100 feet above the surface of the earth. He alighted safely twenty miles from Rouen.

Fatal accident.—It is not a little remarkable, that, among so many aerial excursions, few serious accidents have happened to the aeronauts. The voyage now to be noticed, is one which terminated fatally. In April 1806, M. Mosment, who was no untried adventurer in the regions of the air, ascended from the city of Lisle, at 12 o'clock, mid-day, in presence of a vast concourse of spectators, whose tumultuous acclamations accompanied his progress, while he waved a splendid banner, decorated with the insignia of the emperor of France, in token, as it might seem, of the abject subjugation of those who witnessed the exhibition, and of the uncontrouled dominion of that ambitious power. He mounted with great rapidity, and in a short time disappeared from the sight of the populace. An animal which he carried with him was sent down with a parachute, and reached the ground in safety; but about an hour after his ascent, something was seen floating in the air, and moving slowly towards the earth; and when it came down, it was immediately recognised to be the flag of the aeronaut. This excited very alarming apprehensions for the safety of M. Mosment himself; and the discovery of his lifeless body, covered with blood, in one of the ditches of Lisle, afforded a melancholy proof that they were not groundless. It cannot be certainly known to what this unfortunate accident was owing; but it was conjectured, that the car being very shallow, he might have lost his balance in detaching the parachute for the descent of the animal, or in performing some other necessary manœuvre in the voyage. The balloon was wafted more than 70 miles from Lisle, and came to the ground the same day. A small portion of bread, a bit of flesh meat, and an unloaded pistol, were the only things found in the car.

Nocturnal excursions.—The French, whose curiosity was probably in some degree satiated with the repetition of aerial voyages in the ordinary form, now sought gratification in varying the exhibition; and the resources of that ingenious people were not exhausted in diversifying this interesting spectacle. The daring spirit of M. Garnerin fitted him for undertaking a nocturnal aerial excursion; and the first voyage of this description which he attempted took place on the 4th of August 1807, which might be regarded as an aerostatic festival, in honour of the treaty of peace which had been concluded between France and Russia; and in compliment to the latter power, he ascended under its flag. The balloon was splendidly illuminated by twenty lamps, which were suspended at least fourteen feet below it, that the danger of communication with the inflammable air might be avoided; and to obtain still greater security, tubes were so arranged for its escape, that it might pass off in an opposite direction from the burning bodies. At eleven o'clock at night the balloon was launched into the air from Tivoli near Paris, and soon rose to such a height, that rockets sent up from the same place seemed to the voyager to be a very short way above the earth, and the lofty buildings of Paris, with its numerous lamps, appeared to present only a plain surface marked with shining spots. In forty minutes he had attained an elevation of more than 13,000 feet, when the balloon was so much distended, that it became necessary to permit part of the gas to escape. At midnight he had descended to a region not higher than 3600 feet above the earth, when the barking of dogs was distinctly heard; and in one part of the voyage, meteors were seen darting from one quarter of the heavens to another. Between three and four o'clock, the sun, emerging from a sea of clouds, rose in radiant splendour, and the influence of his rays expanding the included air, the balloon mounted rapidly to the height of 15,000 feet, a region of intense cold; and having pursued his devious course in the atmosphere for more than seven hours, the voyager terminated his expedition at Loges, 140 miles from Paris.

A similar enterprise had nearly proved fatal to the same intrepid voyager. In this excursion, M. Garnerin had agreed to admit a companion to share his adventures; but the lowering aspect of the heavens indicating a storm, induced him to encounter its dangers alone, and to refuse compliance with the urgent solicitations of his disappointed friend. On the 21st of the following September, at ten o'clock at night, he ascended from Tivoli, and darted upwards with astonishing rapidity, to a great elevation, where the expansive force of the included air became so great as to threaten an immediate rupture of the balloon; and as the eager curiosity and pressure of the crowd had interrupted the aeronaut in the regulation of his apparatus for the escape of the gas without risk of communication with the burning lamps, he was compelled, in this perilous extremity, to make an opening two feet in diameter with one hand, while he extinguished with the other all the lamps within his reach. The storm increasing, the machine was driven upwards at one time with great violence, and at another sunk suddenly towards the earth. Having expended the whole of his ballast to recover the power of ascent, and the valve for the escape of the gas being rendered useless, he was altogether at the mercy of the tempest. Now tossed about in the midst of the boisterous elements,—now dashed to the ground, and rebounding to a great height in the air,—and now driven with great fury against the mountains,—the unfortunate aeronaut was for some time thrown into a state of insensibility. When he recovered his senses, he had reached Mont Tonnerre, while the thunder-storm continued with all its violence; his anchor was entangled in a tree; and, after a most perilous voyage of more than seven hours duration, he alighted on the ground 300 miles distant from Paris.

Mr Sadler ascends from Bristol.—On Monday the 24th September 1810, Mr Sadler, accompanied by Mr Clayfield of Bristol, performed his 16th aerial voyage. They ascended from that place at twenty minutes past one o'clock. The wind blew fresh from the N.E. The machine rose majestically; and although the ascent was extremely rapid, the aeronauts were not sensible of any motion. When at the height of half a mile, the balloon was involved in a thick black cloud, which concealed Bristol and its vicinity from their view. Soaring rapidly aloft, they soon passed through the cloud, and, looking downwards, saw in its centre the shadow of the balloon, surrounded by a beautiful halo or circular rainbow. The balloon still continued to ascend, and soon entered a second cloud. Having passed over the river near Redcliff, a parachute, with a cat in a basket, was detached. For some time the descent was very rapid; but when the parachute had reached its full expansion, it assumed a slow and graceful motion.

Leaving behind the Somersetshire coast, the voyagers were carried over the Channel; and when about mid-channel the valve was opened; soon after which they descended so low as to hear the shouts of the people and the sound of the breakers between Barry and Scilly islands. But as the current of air now impelled them towards the sea, and they were apprehensive of not being able to reach the main land, a quantity of ballast was thrown out. The balloon still continuing to descend towards the sea, a quantity of sand was shaken from a bag; but as this produced no effect in retarding the descent, several bags were thrown out, when the motion was instantaneously reversed, and in its ascent the balloon came in contact with the sand first projected, which fell in a copious shower on the car. The occurrence of this curious incident shews the great velocity of the balloon's descending motion, which far outstripped the descent of the sand, and having acquired an ascensive power by the discharge of ballast, met the sand proceeding towards the earth, comparatively with a slow motion. The balloon continued its ascent till 40 minutes past three o'clock, when it approached the Devonshire coast, the whole of which, with Lundy island, and part of Cornwall, appeared before them; on the right was seen St George's channel, with part of the Irish and Welsh coasts; and the Flat and Steep Holmes, and the coast of Monmouth, were observed behind.

It was now past four o'clock, and the aeronauts were anxious to reach the land. For this purpose they threw out almost every thing in their possession,—all their instruments,—a great coat,—a grappling-iron,—and even part of the interior covering of the car; but the dissipation of the gas was so great, that they saw the machine could not rise to a sufficient height to surmount the lofty cliffs on the coast. The balloon descending rapidly towards the sea, the voyagers secured themselves with life-preservers; and in a few minutes afterwards the car dashed violently into the water, at the distance of four miles from land. The car nearly filled with water, was dragged by the balloon, which was impelled along the surface of the sea by the wind, and was drifting fast from the shore. In this perilous situation they continued for an hour, when a well-manned boat, dispatched by some gentlemen from the cliffs of Lymouth, approached, and received them on board; but two hours elapsed before they could exhaust and secure the balloon. Fatigued with the toils and dangers of the aquatic part of their excursion, the voyagers did not reach the pier of Lymouth till nine o'clock at night. They were hailed with acclamation in every town through which they passed on their way to Bristol, where they arrived on Wednesday, and were greeted with the most joyous welcome which the warmth of friendship could express.

Mr Sadler's ascent from Dublin.—The same enterprising aeronaut undertook an excursion from Dublin, for the purpose of crossing the Irish channel. The balloon was of a spherical form, 55 feet in diameter, and was only two-thirds filled, to allow space for the expansion of the included gas in the higher and rarer regions of the air, and the car was loaded with 1100 pounds of ballast. He ascended from Belvidere-house, in the vicinity of Dublin, a little before one o'clock, afternoon, on the 1st of October 1812, in presence of the ladies of the vice-regal court, a great assemblage of beauty and fashion, and an immense concourse of spectators. When he launched into the atmosphere, the barometer stood at 29° 95, and the thermometer at 63°; but in eighteen minutes he had attained such an elevation, that the barometer sunk to 23°, and the thermometer to 49°. He was now approaching to the regions superincumbent to the Irish sea. The balloon was greatly distended, and the voyager was in no small degree alarmed, when he perceived a rent in the silk, where the tube through which the valve cord passes is united with the balloon, and a copious stream of gas issuing from it. The distension of the balloon had given it more of a globular form, so that the lower part of it was beyond his reach, even when he stood on the hoop to which the car was suspended. With some difficulty he made a ladder of ropes, by tying cross pieces to the net-cords, and, with great hazard, mounted this temporary structure, by placing a foot on each side to preserve his balance, and succeeded in closing the orifice, by passing his neckcloth several times round the tube and contiguous parts of the silk. A giddiness, produced by the stream of gas rushing in his face, while engaged in this necessary operation, rendered his situation still more perilous; but although he was nearly overpowered, and the effects of it continued for some time, he regained the car without accident. The gas, as it issued from the opening, felt warm; and when examined by the thermometer, which in the air stood at 42°, it raised it to 71°, indicating a difference of 29 degrees.

The balloon, still continuing to ascend, had reached a current of air from the N.E., but the valve being opened, it sunk, and regained the current from the S.W.; and being carried obliquely across the channel, about two o'clock the voyager had a distant view of the Isle of Man; in the short space of eleven minutes, he saw distinctly the towns, villages, and enclosures; and in twenty minutes more, floated above its south-eastern shore. This course promised a speedy arrival on the Cumberland coast; but as the aeronaut was anxious to terminate his excursion in Lancashire, he discharged some ballast, and again mounted into the north-east current. At four o'clock he was over the island of Anglesea, when the barometer fell nearly to 15°, and the thermometer to 31°. He was now more than three miles above the surface of the earth.

Disappointed of a favourable current of air to enable him to reach the land, and observing the approach of evening, Mr Sadler determined to avail himself of the assistance of several vessels in the channel. He opened the valve, and in a few minutes was precipitated into the sea; but how greatly was he mortified to find, that the vessels, not more than a mile distant, and from which so conspicuous an object could not be unnoticed, continued their course, and left him to seek elsewhere more friendly aid. He threw out some ballast, reascended to a considerable height, and from his lofty station regained another prospect of the orb of day in full splendour, while to the world below that luminary had sunk below the horizon, and with a few reflected rays had formed over sea and land a twilight scene. But this temporary accession to the day was nearly spent; the voyager seeing another vessel from whose signals kinder intentions might be expected, pulled the valve and descended to the sea. But the force of the wind impelled the floating machine with considerable velocity along the surface of the water; and the grappling iron, with great part of his clothes which he had stripped off, being sunk, to retard its progress till the vessel should reach it, and still proving insufficient, the valve was opened to diminish its buoyant power by the escape of a quantity of gas, when instantly the loaded car, no longer supported, sunk, and left the aeronaut to secure himself, by seizing the cane-hoop and afterwards the netting of the balloon. In this perilous situation he was for sometime dragged through the water, and frequently immersed under its surface, till at last the vessel approached, and no other resource being left to save the exhausted and sinking adventurer, the bowsprit was run through the balloon, a rope was thrown to him, he was taken on board nearly in a state of insensibility, and the aerostatic apparatus being secured, he arrived at Liverpool next morning.

When Mr Sadler descended the second time, and the moment that the car touched the water, a flock of sea fowl crowded around the balloon, and eagerly pursued the floating machine as it was wafted along. He supposed that they were attracted by the fragments of bread which were scattered on the surface of the sea; and in this he was soon confirmed, by their boldly rushing upon him in a body, and voraciously devouring what remained of his stock of provisions. The description of these birds corresponds with the species known by the sailors under the name of *Mother Carey's chickens*, the *procellaria pelagica, Lin.* or stormy petrel.

This aerial excursion affords a fine illustration of the opposite currents of air in different regions of the atmosphere. In the higher region, the direction of the current was from the south-west; but in a less elevated region a north-east current prevailed steadily for several hours. The same fact is also exemplified in an aerial voyage performed by Mr Sadler, junior, in which he was accompanied by a lady, in July 1815. He ascended from Norwich, rose to a considerable height, was carried over the sea eighteen miles, discharged some ballast, by which he reached a greater elevation, and floating in a different current, retraced his course, and alighted safely not more than two miles distant from the place of ascent.

It would be easy to extend our narrative of the history of aerial navigation to a much greater length; but without variety of incident or novelty of observation, we should indulge in useless repetition, and contribute nothing to the instruction or amusement of the reader. We now proceed to treat briefly of the construction, management, and uses of aerostatic machines.

Construction of Balloons.—For the purpose of ex-

Aerostation.

hibiting the ascensive power of balloons, they may be constructed of thin paper, varnished with lintseed oil, when they are to be filled with hydrogen gas. But if they are to be distended with rarefied air, it has been recommended to impregnate the paper with a solution of alum, sal ammoniac, or some other salt, by which the danger of fire from the materials employed in sustaining the rarefaction of the air is greatly diminished. The paper is cut in the usual way, and pasted together at the edges. An opening is left at the lower end of the balloon, in proportion to its size, for admitting the rarefied air or the introduction of the matters by the combustion of which the heat is kept up. A small wire is passed round the orifice, and secured at its edges, to preserve the distension; and cross wires are placed within to support a light vessel, containing the spirit of wine, which is usually employed, or what answers better, a piece of sponge or a quantity of cotton thoroughly soaked with the same fluid. When the balloon is distended by bringing it near a fire, or holding a heated body under the aperture, the vapour of the spirit of wine from the sponge or cotton is set fire to; and when the included air is sufficiently rarefied, the machine makes an effort to ascend in proportion to its size and the rarefaction of the air. Balloons intended merely to illustrate the principle, should not be constructed of a smaller magnitude than two feet in diameter; but this depends on the weight of the covering employed; for if the weight of the covering should exceed the difference of weight between the included air and the same bulk of atmospheric air, the balloon will not rise.

Fire balloons of a large size, or such as are intended for aerial voyages, have been usually constructed of an oval form, or in the form of an inverted and truncated cone. This shape, it is supposed, allows the rarefied air to expand as it ascends from its natural tendency towards the top, while the colder air occupies the lower and narrower part. Balloons constructed on this principle, have been usually made of a large size. The covering is linen cloth, soaked in a solution of alum, to preclude as much as possible the danger of fire, and varnished to prevent the escape of the air. The aperture at the lower part, to admit the heated air, is recommended to be of a cylindrical form, to extend at some distance from the body of the balloon, and to be at least one third of its diameter, when it exceeds 50 feet. The fire-place for burning the fuel is placed within the tube, that the rarified air may ascend to sustain the expansion. The fuel usually employed was chopped straw, wool, loppings of vines, and other matters which yield a great deal of smoke. But as balloons of this nature have been superseded by those filled with hydrogen gas, it would be needless to enter more minutely into their description.

Balloons filled with hydrogen gas are generally of a globular form. The covering is a fine silk, called tiffany or lutestring, with a network interwoven in its texture, which gives it additional strength; and to add to the attractive appearance of the machine, it is sometimes composed of alternate stripes of different colours. To render the silk less permeable to the gas, it is carefully varnished. Different kinds of varnish have been recommended. A varnish of elastic gum, or caoutchouc, is, we believe, now generally employed; and is prepared by the following process. The caoutchouc, or Indian rubber, is cut into small pieces, and dissolved in five times its weight of spirits of turpentine. Several days are necessary to complete the solution; when this is effected, one ounce of it is added to eight ounces of drying lintseed oil; the mixture is boiled for a few minutes; it is then strained, and is fit for use. This is the method for preparing the elastic gum varnish which was adopted by Blanchard, who had great experience in the construction of aerostatic machines. The solution is applied warm, and with a flat brush, to the silk well stretched. One coat of varnish is found sometimes to answer; but if two are required, the first must be allowed to dry before the application of the second. It was usual to cover both sides of the silk with varnish. But it appears from the experience of the superintendants of the Aerostatic Institute in France, to be afterwards noticed, that balloons varnished only on the outside are the most durable; for the elastic gum varnish is corroded by the gas, and leaves the silk in a flabby state. The silk being varnished is cut into pieces or gores for forming the balloon, exactly in the same way as the paper for covering globes. The different pieces are cut larger than the pattern, that the edges may overlap; and they are united by passing a heated iron with an intervening fold of paper along them, which slightly melts the gum and makes the pieces adhere; and to give the joining greater strength and security, it is stitched with a thread along the seam.

To find the quantity of cloth required for the covering of a balloon of a spherical form, the square of the diameter is multiplied by the number 3.1416. Thus, in a balloon of thirty feet, the square of the diameter is 900, and this number multiplied by 3.1416, gives $2827\frac{1}{2}$ feet nearly for the superficies; and this last number being divided by 9, the quotient is 314, or the square yards in a balloon of that size. The weight of the whole covering is found by weighing one yard of the silk, and multiplying the number of yards employed by that weight. The capacity or solid contents of a balloon of a globular form is estimated by multiplying the cube of the diameter by the decimal .5236; as, in the balloon of 30 feet diameter, the cube is 27,000, and this multiplied by .5236 gives 14,137 cubic feet. The balloon with which Mr Sadler ascended from Dublin had a surface of 9503 square feet; and its solid contents amounted to 87,133 cubic feet.

To ascertain the ascensive power of a balloon, the difference of weight between the hydrogen gas and an equal bulk of atmospheric air must be calculated. The weight of a cubic foot of atmospheric air is estimated at one ounce and two-tenths nearly. The weight of a mass of atmospheric air equal in bulk to a balloon of 30 feet diameter, whose solid contents are 14,137 feet, amounts to 1060 pounds. The hydrogen gas with which balloons are filled, is about 6 times lighter than common air. This makes the weight of a balloon of 30 feet diameter filled with hydrogen gas, to be 176 pounds nearly; and if the yard of silk be estimated at one pound, the weight

Aerostation. of the covering is 314 pounds, the number of yards required for a balloon of this size. The weight of the covering and the included gas being subtracted from 1060 pounds, the weight of an equal bulk of atmospheric air, leaves 570 pounds as the power of ascent of such a balloon. In the same way the ascensive power of balloons of any other size may be calculated.

The balloon is furnished with a valve usually placed at the upper part of the sphere, but sometimes at its side. The valve presses on the orifice, of several inches in diameter, by means of a spring; and it is opened by pulling a cord which passes through the balloon and the silken tube to the car, to permit the gas to escape when necessary. The silken tube, of six or eight inches in diameter, receives the gas from the apparatus in which it is prepared, and conveys it to the balloon; and when the latter is sufficiently distended, the tube is secured with a ligature. A net made of the best materials, usually we understand of Italian hemp or of French cambric thread, to combine lightness and strength, is spread over the whole balloon, and the cords which terminate the net at the lower part are fastened to a light cane hoop. To this hoop the ropes by which the car is suspended are attached. The car, somewhat in the form of a boat, is made of wicker work, or some other light material, covered with well varnished leather. The splendid and costly car which Mr Sadler exhibited at Glasgow and Edinburgh in 1815, and in which it is said that aeronaut proposed to ascend at the coronation of the king of France, has a double covering of elastic gum, between which there is a stratum of included air, which gives it additional buoyancy; and from this construction it has the advantage of being a life-boat in case of falling into the water. The car is of sufficient magnitude commodiously to admit of two persons, besides the instruments for making observations, and the necessary ballast, which is commonly sand put up in small bags. When the aerial voyage is in the vicinity of the sea, the aeronaut provides himself with a life-preserver. A convenient form of this necessary apparatus, is a cylindrical hoop of thin copper, divided into air-tight cells, and so constructed as to fit the trunk of the body, under the arms, where it is attached.

Preparation of hydrogen gas.—The gas which is employed in filling balloons, is usually obtained from iron, sulphuric acid, and water. About 2000 pounds weight of the turnings or borings of cannon, and an equal weight of sulphuric acid, or the oil of vitriol of the shops, diluted with six times its weight of water, is supposed to yield a sufficient quantity of gas to fill a balloon of thirty feet in diameter. Lunardi had a very simple apparatus for preparing the gas. Two casks were sunk in the earth, to strengthen them, and preclude the risk of bursting. The iron turnings were put into the casks, and, to expose a greater surface to the action of the acid, they were separated into layers, by a quantity of straw interposed. The diluted acid was added; and the gas, as it arose, was directly conveyed to the balloon, without passing through water to cool it, or to separate the sulphurous acid, which, it is probable, was copiously evolved by the action of the vegetable matter during the process. This method was greatly improved, by having a number of casks communicating with a large one inverted over water, from which the gas, after passing through the water, is introduced into the balloon. In this way it is both cooled and purified from those substances which increase its specific gravity, or tend to corrode the silk. A quantity of quick-lime is mixed with the water for the same purpose. The number of casks and coolers is to be proportioned to the size of the balloon, or the time allowed for filling it; and it is found convenient to have the casks in which the ingredients are placed lined with tin-plate. The apparatus which Mr Sadler employed in procuring hydrogen gas for his ascent at Edinburgh in 1815, consisted of a leaden cistern inclosed in a wooden box, and covered with loose boards kept down with weights, to resist the expansive force of the gas. The cistern was about eighteen feet in length, three feet in breadth, and two in depth. A tin-plate tube, of seven or eight inches in diameter, conveyed the gas from the cistern to a cooler; and having passed through the water, it was conducted through a similar tube to a second cooler, from which it passed into the balloon. With this apparatus, a balloon of thirty-six feet in diameter was filled in two hours and a-half. It is scarcely necessary to add, that the balloon must be held down as the distension proceeds, to prevent its escape, as has happened in some cases, and that the compressed covering is introduced into the net before the filling commences.

The Aërostatic Institute, at Meudon in France, obtained the hydrogen gas from the decomposition of water, by means of red-hot iron. For this purpose, six or eight hollow iron cylinders are set in brickwork in a furnace. The projecting ends of the cylinders are stopped with strong iron covers, through which pass metal tubes for introducing the water at one end, and conveying the gas, as it is formed, from the other. The cylinders are partly filled with coarse iron filings; and when they are sufficiently heated, boiling water is admitted through a valve, and as it comes in contact with the red-hot iron, it is decomposed; the oxygen combining with the iron, and the hydrogen passing off by the other end, is first conveyed through water in which some alkaline matter is dissolved, and then into the balloon in a cool and purified state. By this process, which appears to possess the advantage of being economical, a balloon of thirty feet in diameter is filled in eight hours.

To allow space for the expansion of the included gas in the higher and rarer regions of the atmosphere, the balloon should not be filled more than five-sixths, or perhaps not more than three-fourths, according to the elevation which the aeronaut proposes to reach.

Management of Balloons.—In conducting a balloon, the whole art of the aeronaut is nearly limited to its ascent or descent in the atmosphere; and here he has complete power over his machine; for, by pulling the valve, and permitting a quantity of gas to escape, its buoyancy is diminished, and it descends, and by discharging ballast the machine is lightened, and its ascensive power increased, so that it attains a greater elevation. The course of a Aerostation.

balloon in the air is exactly the same as the current of air in which it floats. No attempt yet made has succeeded in giving it a different direction. The application of wings, oars, and rudders, has been tried in vain; no sensible effect is produced, except a rotatory motion, which, Mr Sadler informs us, can be communicated merely by waving the flag.

Parachute.—The dangers of aerial navigation, which, it ought to be observed, are far less formidable than might at first be expected, and the fatal accidents which have befallen some aerial travellers have probably suggested the invention of the parachute, by which the aeronaut might descend safely to the earth, when his situation with the balloon became dangerous. The construction of the parachute is similar to that of an umbrella. The parachute which M. Garnerin employed, when he came down from a balloon at London, in 1802, consisted of thirty-two pieces of canvas; and the whole, when united and expanded, presented a diameter of twenty-three feet. Each gore, or piece of canvas, was fastened with a cord to a round piece of wood, ten inches in diameter, and perforated in the centre; and between four and five feet from the top of the canvas, a wooden hoop was secured, by small cords from each seam. From the edges of the parachute a number of ropes, about thirty feet in length, passed downward, and were united at their extremities; and the circular basket for the aeronaut was suspended by shorter ropes proceeding from the common joining. With a parachute of this description, M. Garnerin descended near London, in September 1802, from an elevation of 8000 feet. The same enterprising aeronaut has frequently repeated the experiment; and in summer 1815, Madame Garnerin, who has been his companion in many aerial excursions, boldly attempted, and successfully achieved, the same daring exploit at Paris.

In most cases the adventurers have reached the ground in safety by this mode of conveyance. But parachutes of this construction are subject to the serious inconvenience of an oscillatory motion in one part of their descent. This motion, which is not altogether free from danger to the aeronaut, commences when the full expansion of the parachute takes place, and is no doubt owing to the air compressed in the concavity, and escaping unequally under the edges. To obviate this inconvenience and danger, a perforation of two or three feet in diameter, in the centre of the parachute, to allow the compressed air, before it accumulates, to escape, has been proposed. It has been suggested also, that a parachute constructed in a form exactly the reverse of that now described, namely, by presenting the convex surface downwards, would descend with an undeviating vertical motion. This suggestion, first started, we believe, by Sir George Cayley, who has published some ingenious speculations on aerial navigation, *(Nichol. Jour. vol.* 24.*)* is confirmed by experiments on a small scale. Mr Kerr, of Edinburgh, has favoured us with a communication, in which a still more plausible improvement is proposed, and has been also submitted to the test of experiment. The parachute, according to Mr Kerr's construction, is in the form of an inverted cone, from the point of which proceed the ropes by which the basket for the aeronaut is suspended. The edge of the parachute is turned downward, forming a circular concavity. By this construction there can be no accumulation of air in the central parts of the parachute; and the compression which takes place in the concavity near the outer rim, promises to give it greater stability in its descent.

Uses of aerial navigation.—The advantages of navigating the air with balloons, if we except the additions made to the stock of meteorological knowledge, are far less considerable than the first discovery of this wonderful art seemed to hold out. The most material facts which have been observed in the upper regions of the atmosphere, are already noticed in the detail of particular voyages in the preceding narrative. But although the utility of this art has been hitherto extremely circumscribed, and its improvement has been long stationary, it would be rash to conclude that some fortunate discovery may not render it one day a valuable acquisition to science, and highly beneficial to mankind.

It has been proposed to employ balloons in making surveys of countries, a purpose for which they are surely but ill suited, on account of their instability. It has been also suggested, that they might be successfully employed in communicating signals. The first actual application of this art was made by Coutel, who, accompanied by an adjutant and a general, ascended with a balloon on the 26th of June 1794, to reconnoitre the hostile armies at the battle of Fleurus. Twice on the same day he mounted to the height of 440 yards, to observe the position and manœuvres of the enemy; and each time he remained four hours in the air, and, by means of signals, held a correspondence with General Jourdan, the French commander. When the balloon first arose, the enemy opened the fire of a battery against it, and one ball passed between it and the car. In the subsequent discharges the aeronauts had reached such an elevation as to be beyond the range of cannon shot, and saw the balls flying beneath them. Arrived at their intended height, it is added, the observers, remote from danger, and undisturbed, viewed all the evolutions of the enemy, and, from the peaceful regions of the air, commanded a distinct and comprehensive prospect of two formidable armies engaged in the work of death.

An aerostatic telegraph has been constructed by the French. It consists of eight cylinders of varnished black silk, stretched on hoops, each three feet in diameter, and of a proportionate length. These moveable cylinders are suspended from the bottom of the car, connected together with cords, and hanging one above another at the distance of four feet. By means of cords passing through the bottom of the car, the observers direct the cylinders, give them different positions at pleasure, and thus conduct their telegraphic correspondence from the regions of the atmosphere. M. Conté, from whose ingenuity this invention derives its origin, has projected another kind of aerostatic telegraph, with which a person on the ground may carry on an aerial correspondence, by means of cords, and this may be managed with the apparatus suspended to a balloon of ten or twelve feet in diameter.

Aerostation.

The only public establishment for the improvement of aerial navigation, was the Aerostatic Institute, founded by the committee of public safety, during the period of the French republic. This establishment, which was fixed at Meudon, not far from Paris, was placed under the superintendance of Guyton Morveau, the celebrated chemist, and under the immediate direction of M. Conté, already alluded to as the inventor of the aerial telegraph. The corps of aeronauts, who were destined to serve in the armies of the republic, was composed of fifty young men. With this establishment was connected a camp for the exercise of artillery; and all its affairs were conducted with the utmost precaution, and the most profound secrecy. The doors were kept shut not only against all foreigners, but also against the public, whom curiosity might attract to witness the methods of instruction and training. During the summer season, the pupils were daily engaged in the performance of aerostatic exercises, as well as in the acquisition of those branches of natural philosophy which are closely allied with the objects of the institution. The exercising balloon was of a spherical form, and thirty-two feet in diameter. The upper half was covered with a linen case to protect it from the rain. The car and other apparatus were arranged and secured in the usual way. The balloon was kept constantly full and ready for ascent, and, being held down by means of ropes, preserved its buoyant station in the atmosphere. When the weather was favourable, the aeronautic exercises commenced; a colonel mounted with one of the pupils, and the machine was allowed to rise to the height of 160 or 240 yards. The pupils were formed into divisions for the purpose of regulating the ascent of the balloon in the air, by means of three principal ropes proceeding from the net and branching into others. In directing these manœuvres the aid of a capstan was employed; for when the balloon was recently filled, and had lost nothing of its buoyant power, the strength of twenty persons was requisite to hold it, and then it was capable of supporting 800 pounds; and even at the end of two months, the ascensive power was so little exhausted, that it was capable of rising to the same height in the air with two persons, all their instruments, and a considerable quantity of ballast.

The French nation, whose mad career of military enterprise had just commenced, seem to have cherished the most ardent hopes of the advantages to be derived from this establishment in accomplishing their wild schemes of ambition; but these hopes were never realized: the institution was of short duration; it has been entirely abandoned, and it does not appear that it has bequeathed any benefit to the art of aerial navigation. No similar institution has ever arisen under the fostering care of public patronage. The improvement of the art is at present exclusively confined to the fortuitous observations of aeronautic adventurers, whose chief object, it is most natural to suppose, is immediate emolument; and although their efforts, in exhibiting the gratifying spectacle of an aerial voyage, have been in general pretty liberally rewarded, yet the great expence of such experiments precludes their frequent repetition, and consequently narrows the bounds of useful discovery by which its progress might be advanced. The art of aerostation may be regarded as yet in its infancy; the wonder and astonishment excited by an aerial voyage have scarcely subsided; and the contemplation of the long intervening period from the rude essay of floating down the stream on an unformed mass of wood, to the high degree of perfection which the art of navigating the trackless ocean has attained, encourages the hope, that the resources of ingenuity in the improvement of sailing in the atmosphere are far from being exhausted. It is true, the fluid in which the airy vehicle floats and the moving power are the same; but still, the difficulty of directing the machine may be surmounted by some happy contrivance, some fortunate application of the very means at this moment within the power of man.

Explanation of Plate I.

Fig. 1. represents the rarefied air balloon, 76 feet in height, and 45 feet wide, with which Pilatre de Rozier and the Marquis D'Arlandes ascended from Paris, and performed the first aerial voyage.

Fig. 2. M. Blanchard's balloon, furnished with the apparatus of wings, or oars, for the purpose of steering.

Fig. 3. The balloon of Mr Sadler, junior, with a view of the buildings of the College of Edinburgh, from which place he ascended in November 1815.

Æruscatores.

ÆRUSCATORES, a name applied by the ancients to strolling beggars, or gypsies, who supported themselves by fortune-telling. A similar denomination was given to the collectors of the revenue, and also to the priests of Cybele, the mother of the gods in heathen mythology, who went about the streets soliciting alms; a practice which seems to resemble that of the mendicant orders of certain establishments connected with religion in modern times, and from which, perhaps, it may have derived its origin.

Æschines.

ÆSCHINES, a celebrated Grecian orator, and the formidable rival of Demosthenes, was born at Athens, 327 years before the Christian era. His own account traces his descent from an illustrious family; while that of Demosthenes, perhaps not strictly impartial, represents him as the son of a courtezan, and at one period of his life a humble performer on the stage. The talents and acquirements of Æschines, which raised him to the rank of competitor with the great Grecian orator, could not be of an ordinary kind; and the rivalship which subsisted between them, and which at last burst out into violent and open hostility, forms the most memorable event in the life of Æschines which has been transmitted to posterity. The two orators had become the leaders of opposite parties; and urged by mutual jealousy and animosity, were probably not slow in finding matter of accusation against each other. Demosthenes charged Æschines with taking bribes while employed in an embassy. Æschines indirectly retorted the charge, and accused Ctesiphon, the friend of Demosthenes, for proposing an illegal decree to

BALLOONS

Engraved by W. Miller

confer a golden crown on the latter as a mark of public approbation. The matter came before the judges, and a numerous assembly of citizens. The orators exerted all the powers of eloquence; and on this occasion Demosthenes pronounced his most splendid oration, which derives its title,—*Concerning the Crown*,—from its subject. Æschines was condemned to exile; the resentment of his opponent melted into kindness: Demosthenes presented him with a sum of money, which produced an expression of regret to leave a country in which he found so generous an enemy, that he despaired of ever meeting such a friend. Æschines taught eloquence at Rhodes, and afterwards removed to Samos, where he died, in the seventy-fifth year of his age. Three only of his orations are extant. The eloquence of Æschines is acknowledged to be energetic; but it is diffuse, loaded with ornament, and more suited to please than to rouse the passions.

ÆSCHYLUS, a Greek tragic poet, was a native of Athens; but the time of his birth is variously fixed by different authors, in the sixty-third, the sixty-fifth, and the seventieth Olympiad. The father and two brothers of Æschylus acquired great renown in the famous battle of Marathon, and the equally celebrated naval engagement of Salamis. The poet, also, it is said, shared the glory of these splendid victories; but the younger brother, Aminias, peculiarly signalised himself by deeds of heroism. To this brother Æschylus was indebted for his life; for being charged with impiety, he was condemned to be stoned to death. At the moment when the sentence was to be executed, Aminias came forward, threw open his cloak, and presenting his arm without a hand, which he had lost in defence of his country, roused his fellow-citizens to a recollection of his own bravery, and obtained a remission of the punishment, and pardon for his brother.

Æschylus is to be regarded as one of the first reformers of the stage: He introduced the dialogue between two persons, as well as the mask and buskin, with appropriate dresses for the actors; and he arranged the chorus, which formerly held a chief place, in a subordinate station in the action represented. Of a great number of tragedies composed by Æshylus, seven only are known to be extant. They have been universally admired in all ages. They are distinguished by a simple and natural plot, grandeur and sublimity of thought, and bold and vigorous language, abounding in striking and uncommon metaphors. Æschylus withdrew from his native country towards the close of his life, in consequence, it is said, of the indignity to which the prosecution had exposed him, or of the rising fame of Sophocles, another tragic poet, whose works had acquired great popularity. He retired to Syracuse; and it is recorded that he was killed in the sixty-ninth year of his age, as he was walking in the fields, by the strange accident of a tortoise dropped from the air by an eagle, and falling on his head. The Sicilians paid great respect to his memory; he was honoured with a pompous funeral, and theatrical entertainments were exhibited at his tomb.

ÆSCHYNOMENE, or Bastard Sensitive Plant, a genus of plants belonging to the class Diadelphia.

ÆSCULAPIUS, according to the heathen mythology, was the god of physic, and the son of Apollo and the nymph Coronis, received his education from the centaur Chiron, and became so skilful and celebrated for the cure of diseases, that Pluto, alarmed that his domain should be deprived of its population, complained to Jupiter, who slew Æsculapius with a thunderbolt, and banished him to the infernal regions. Apollo revenged the death of his son, by destroying with his arrows the Cyclops who forged the thunderbolt. The fabulous records of antiquity describe three deities of the same name, as the reputed authors of useful inventions or valuable discoveries in medicine and surgery; or perhaps the same personage is referred to under a different form and character. Æsculapius was worshipped under the form of a serpent, at Epidaurus, where his most celebrated temple was erected. This famous shrine contained a statue of the god in gold and ivory, which represents him as an old man with a long beard, and clothed in a loose robe, the head surrounded with rays, and a rugged stick in one hand, while the other is entwined with serpents. Games instituted in honour of the god of physic were celebrated, with great pomp, at Epidaurus every five years; and the cock, the raven, and the goat, were sacred to the same deity.

ÆSCULUS, the Chesnut and Horse-chesnut, a genus of plants belonging to the class Heptandria.

ÆSOP, the celebrated author, or supposed author, of the fables which have long afforded delight and instruction to childhood, was a native of Phrygia, and was born nearly 600 years before the Christian era. According to some accounts, Æsop was deformed in person, and, being a slave, continued in a state of servitude with many masters. Having obtained his liberty, the fame of his wisdom procured him an invitation to the court of Crœsus, king of Lydia; and by that monarch he was entrusted with an important mission to Delphi, to offer a sacrifice to Apollo, and to distribute a large sum of money among the people; but, in consequence of a dispute, the money was retained, and returned to Crœsus. The disappointed inhabitants charged Æsop with sacrilege, and he was convicted, and thrown headlong from a high rock. The allusions to be found in the works of Greek and Roman writers to Æsop, as the author of compositions in the form of fables, afford probable proof of such a person having existed; but no connected or consistent sketch of his life has been discovered in any ancient historian. The compilation of the biographical notices prefixed to the modern fables of Æsop in the fourteenth century, renders its authenticity doubtful; and even the collection of the writings which appear under his name, is supposed to have been made at no very distant period; and as it is well known to be a popular mode of conveying moral instruction in eastern countries, it may have been drawn from very different sources.

ÆTHER, from the Greek verb *to shine or burn*, is a term of frequent occurrence in the writings of ancient philosophers and poets, and denotes a fluid of extreme tenuity, or the pure element of fire greatly attenuated, which was supposed to occupy the utmost bounds of space, beyond the regions of our atmosphere, and to be in a state of constant revolution round the globe. It seems also to have been regarded as something of a divine or immortal nature; and the principle of life, and even the soul of man, "a portion of the divine spirit," were thought to be emanations from this æthereal matter. It would be in vain to search for any definition, or precise meaning of this term, in the works of ancient authors; and, perhaps, considering the variety of significations under which it has been employed, it ought rather to be received as an agreeable poetical fiction, than a philosophical truth. But in whatever sense it is used, when applied to natural objects, it invariably expresses something which is exceedingly pure and refined; and when it refers to animated or rational beings, it conveys the notion of the most placid enjoyment, the highest felicity.

ÆTHER, a light, volatile, and inflammable liquid, which is prepared by the action of acids on alcohol, when subjected to the process of distillation. Thus, sulphuric or vitriolic æther is obtained, by distilling sulphuric acid and alcohol together. See CHEMISTRY.

ÆTHUSA, Fools Parsley, a genus of plants belonging to the Pentandria class.

ÆTITES, or EGLESTONE, an argillaceus ore of iron, supposed to have been found in the eagle's nest, to which it was carried by the bird, to aid the process of incubation, and hence it derived its name.

ÆTNA, a lofty mountain of Sicily, celebrated from the earliest ages on account of its volcanic eruptions. See SICILY.

ÆTOLIA, a country of ancient Greece, including what is now called *Little Greece*, the southern boundary of which extends to the bay of Corinth. The Ætolians are described in different periods of their history, as a turbulent and restless people,—as plunderers or robbers, and in a state of constant hostility with their neighbours,—as inured to hardship, and patient of fatigue, dauntless in danger, and bold and enterprising in war;—as strongly attached to the republican form of government, jealous defenders of their liberties, and highly conspicuous among the other states of Greece for their bravery and perseverance in resisting the ambitious schemes of the Macedonian princes. But they were at last forced to submit to the overwhelming power of Philip, and yield up part of their territory to his dominion. The Ætolians, after a long struggle, and various success, were at last subdued by the Romans, and, with the other free states of Greece, were included in the province of Achaia; and the descendants of that brave people are now in a state of the most abject servitude to the Turks.

AFFECTION, when applied to matter, is nearly synonymous with property or quality, or it signifies those changes which are produced on bodies by the action of physical or chemical agents; but affection, considered as a mental operation, is a strong tendency of the mind, produced by some cause or agent, to communicate to others pleasure or pain, enjoyment or suffering. Moral writers have divided the affections into two classes, the benevolent and malevolent:—love, friendship, gratitude, belong to the first; hatred, jealousy, envy, revenge, fall under the second class. The exercise of the benevolent affections is accompanied with the most agreeable emotions, the most soothing delight; but inward agitation and disquiet, often depicted on the countenance, are the certain consequences of the indulgence of those of a contrary character.

AFFIDAVIT is a term chiefly confined to English law, and signifies a declaration upon oath, emitted before a magistrate, and committed to writing. Synonymous with affidavit is the oath of verity required from creditors, according to the Scotch bankrupt act.

AFFINITY is a term in law, expressive of that degree of kindred between a husband and the blood relations of the wife, or the contrary. By such connection, no real kindred is created; for no person can legally succeed to an inheritance in consequence of this affinity, whatever be its degree. The degrees of affinity are computed in the same way as those of consanguinity, or relationship by blood.

AFFINITY is employed to denote that property in the particles of matter by which they unite to form masses or new compounds. That property by which bodies are acted on at sensible distances, and are drawn towards each other, as the sun and planets, or a stone falling to the earth, is known by the general term *attraction*, or the *attraction of gravitation*; but the mutual action of bodies at insensible distances, is distinguished by the name of *chemical attraction*, or *affinity*. The latter term is now in general use in the language of modern chemistry. When the action between two polished surfaces of glass, marble, or metal is referred to, it is denominated *adhesion*; when the particles of the same kind of matter are united in masses, as a piece of stone or wood, it is called *cohesion*, or the affinity of aggregation; and when the particles of different kinds of matter combine together, and form a new compound, as sulphuric acid and lime, the union of which is plaster of Paris, it receives the name of the *affinity of composition*, *chemical* affinity, or simply *affinity*. See CHEMISTRY.

AFGHANS, or AFGHAUNS, a warlike people, who inhabit the mountainous regions on the borders of Persia, and occupy that district of country which lies between the Caspian sea and the Indus on the east, and between the same river and Cachmere on the west. As the Afghans have scarcely any resemblance to their Tartar neighbours, in their persons, manners, or language, the opinion is prevalent that they are descended from the Arabs. Sir William Jones was led to suppose, that the origin of this singular people was probably derived from the Jews; and he thinks this opinion receives confirmation from the accounts of the best Persian historians, from the traditionary history of the Afghans themselves, from the names of the Jewish tribes, by which many of their families are distinguished at the present day, although, it is said, they carefully conceal their origin since their conversion to Mahometanism, and from the affinity of their language to the Chaldaic.

Inhabiting a country inaccessible by nature, and enjoying none of the riches or luxuries which excite avarice or tempt ambition, the Afghans have retained their early customs and original character almost unchanged; and, secure amidst the rugged fastnesses of the mountains, have preserved their independence nearly unshaken. For, although they have nominally acknowledged their subjection to Persia, they were never conquered. Fierce and restless in their dis-

Afghans.

positions, they have been always more distinguished by their warlike achievements than by their love of the arts of civilized life. In the year 1712, they threw off the Persian yoke; advanced into the province of Candahar; took possession of the principal city, and afterwards of the whole province. Another tribe of Afghans revolted in 1717, and formed themselves into an independent republic. Mir Mahmud, a bold leader, united the different tribes of the Afghans with his own forces, for the purpose of subduing the whole of Persia, seized Ispahan, and established his own authority. Under the conduct of Mahmud's successor, the Abdollees, one of the tribes of Afghans took the field against the Turks; concluded a peace with them in 1727, and acknowledged the Ottoman emperor as the lawful sovereign of Persia. When Nadir Shah became master of Ispahan, he drove the Abdollees from their possessions; forced them to renounce their claims; in 1736, invaded their territory, and, having lost many of his troops, offered them peace, and invited them to join his army; and of all the Persian forces, the Afghans are distinguished as the bravest and hardiest soldiers.

AFRICA.

Africa.

AMONG the modern divisions of the globe, Africa ranks as third in point of size, though now inferior to all the other great continents in moral and political importance. Its boundaries are more clearly defined than those of the three other great divisions. They are, on the north, the Mediterranean sea; on the west, the Atlantic ocean; on the south, what is called the Southern ocean; on the east, the Indian ocean; and, on the north-east, the Arabian gulf, or Red sea, which separates it from Asia. Thus it is surrounded by water on all sides, except the narrow neck of land called the isthmus of Suez, by which only it is joined to Asia. In form, it has been represented as triangular, though it more nearly resembles a *trapezium*, the eastern border forming an acute angle at Cape Guardafui. Its general extent is not easily determined. From north to south, it occupies about 70° of latitude, equal to about 4900 British miles; while from Cape Verd on the west, to Cape Guardafui on the east, it extends through the same number of degrees, making its greatest breadth nearly equal to 4690 British miles.

Divisions.—Africa is divided among a great number of distinct tribes, or nations, of many of whom little more than the name is known. They may be classed as follows: On the north lie EGYPT, BARCA, TRIPOLI, BILED-UL-GERID, TUNIS, ALGIERS, FEZ, TAFILET, MOROCCO, and the great desert called SAHARA. Along the western coast lie the FOULAHS, FELOOPS, what is more particularly called the coast of GUINEA, including SIERRA-LEONE, the *Grain* coast, the *Ivory* coast, the *Gold* coast, and the *Slave* coast; the countries of POMBO and CONGO, comprehending LOANGO, ANGOLA, MATAMBA, and BENGUELA. In the southern division are situated the Great and Little NAMAQUAS; the HOTTENTOTS; the colony of the Cape of GOOD HOPE, and CAFFRARIA. The south-eastern coast comprehends the territories of BIRI, INHAMBANE, MANICA, SABIA, SOFALA, and MOZAMBIQUE; and along the eastern coast lie the kingdoms of MONGALLA and QUILOA; the country of the MONOMUGI; the territories of BRAVA, AZANIA, and ADEL; while the eastern shores of the Red sea are occupied chiefly by the extensive empire of ABYSSINIA, and the territories of SENAAR and DONGOLA. Beside these nations on the coast of Africa, the central parts of this great continent are inhabited by several tribes of whom a few only can be here noticed. These territories are SOUDAN, or NIGRITIA, including the empires of HOUSSA and TOMBUCTOO, and the kingdoms of BORNOU and DARFUR, the kingdom of AGADEZ, the territory of DONGA, and the country of the GAGAS.

Mountains.—In a tract of land so extensive as Africa, we might expect the face of the country to to be extremely various; this, however, is not in general the case. The greater part of the interior is composed of vast deserts, one of which comprehends a space of nearly two millions of square miles. The coast is in general low, except in Morocco, at the Cape of Good Hope and near the Mozambique channel; but a very remarkable chain of mountains is supposed to extend right across this continent from Cape Verd to Abyssinia.

Besides this extensive ridge of mountains generally called the Mountains of Kong, and the Mountains of the Moon, Africa boasts of Mount ATLAS, which passes from Biled-ul-Gerid, in a westerly and south-easterly direction, till it terminates in the southern boundary of Morocco. Another ridge runs along the the western shore of the Red sea, and is supposed to have formed the quarries from which the ancient Egyptians derived the materials of their obelisks. A considerable ridge traverses the kingdom of Darfur; and another called the *Mountains of Lupata* and sometimes the *Spine of the world*, forms the western boundary of ZANGUEBAR, extending nearly to the Cape of Good Hope. The only other high land of importance is the celebrated Table Mountain at the Cape. There are some volcanoes in Africa, but these are little known.

Capes.—From the indentations of the African coast, there arise numerous capes and gulphs. The principal capes are the following, viz. Cape Bon, in the territory of Tunis; Cape Spartel, forming the south-western coast of the straits of Gibraltar; Cape Geer, in the kingdom of Morocco; Cape Bojador, remarkable only as being the first new cape doubled by the Portuguese in the commencement of their maritime discoveries; Cape Blanc, in north latitude 21°; Cape Verd, latitude 15°; Cape Palmas, on the Ivory Coast; Cape Three-Points, on the Gold Coast; Cape Formoso, in the territory of WARI; Cape Lopez Gonzalvo, a little south of the equator; Cape Voltas, between the Great and Little Namaquas; Cape of Good Hope, forming the most southern promontory; Cape Sebastian, on the Mozambique channel; and Cape Guardafui, forming the most eastern promontory of Africa.

Gulphs.—The gulphs are very numerous. The most remarkable are those: Sidra, or Syrtu Gouletta, and Cabes, in the Mediterranean; the gulf of Guinea, in the Atlantic ocean; the gulf of Sofala, in the Mozambique channel; and the bay of Zeila, on the southern shore of the straits of Babelmandel.

Rivers.—The rivers of Africa, considering the great extent of this division of the globe, appear not to be so numerous as those of either Asia or America. The interior of the country, in particular, seems nearly devoid of navigable streams, if we except the NILE and the NIGER,—those two great approbria of modern geographers, of which neither the source of the former, nor the termination of the latter, has been ascertained with certainty.

The Nile is supposed to derive its source from that ridge of the Mountains of the Moon that traverses the territory of Donga, whence, under the name of Bahr El Abiad, it takes an easterly and north-easterly course to the borders of Abyssinia. From this it runs nearly due north, between Kordofan and Senaar; traverses Nubia and Dongola, in a winding course; enters Egypt, and passes directly north to the Mediterranean sea.

Of the Niger, much less is known than of the Nile. We know that it originates in the western ridge of the mountains of Kong; from which it flows easterly, north-easterly, and easterly, through the kingdom of Bambara, and the empires of Houssa and Tombuctoo; but whether it terminates in a considerable lake to the west of Darfur, or takes a southerly direction through the Mountains of the Moon, and finally disembogues itself into the southern Atlantic ocean, by one of those openings which are now known under other names, is not yet determined. It seems probable, however, that the Niger does pass to the southward; and if it do not form one continued stream, that it unites itself with the large and rapid river denominated Congo, or Zayr.

The river Congo may be considered as the third in point of importance. Its source is not known, though it evidently comes from the northward, and, after traversing the kingdom of Congo, joins the Atlantic at about the 12th degree of south latitude. Here it is about 15 miles wide, and so rapid as to repel the waters of the ocean to a distance of many miles from the coast. Near its mouth it is a hundred fathoms deep; and at ninety miles above its mouth, its width is a mile and a half, and its depth above thirty fathoms.

The other African rivers of note are, the Senegal and the Gambia, both rising in the mountains of Kong, and flowing into the northern Atlantic, opposite the Cape de Verd islands; the Orange river, which probably rises in the southern ridge of the mountains of Lupata, and flows westerly for nearly 1000 miles, till it meets the southern Atlantic, between the Great and Little Namaquas; the Zambe, opening into the Mozambique channel, and the Hawash into the straits of Babelmandel.

Lakes.—It is probable, that such an extensive tract of country contains numerous and considerable lakes, though few of these are known to modern geographers. The most considerable with which we are acquainted, are, Lake Maravi, to the west of the mountains of Lupata; Tzana, or Dembea, near Gondar, in Abyssinia; Menzala, in Berlos; and Elko, in Egypt; and Maberia, in Nigritia, which is said to give origin to the river Senegal.

Islands.—Several important islands are described as belonging to Africa; especially, Madagascar, reckoned the third island, in point of size, on the globe; the Canary islands, opposite the coast of Morocco; the Cape Verd islands; the island of St Thomas, almost at the equator; and St Helena, which, though insignificant in point of magnitude, is now become of no small importance in the eyes of Europe, as the future residence of Napoleon Buonaparte.

Oases.—Similar to the islands in the Atlantic and Indian ocean, are those remarkable isolated spots of cultivated land in the midst of the extensive African deserts, which give shelter to a few wandering tribes, and afford welcome resting places to the trading caravans. These are called *Oases*, and are pretty numerous. The most remarkable are those of Fezzan, Agadez, Augila, Gualata, Tuat, Taboo, Gadamis, and Berdoa.

Climate and seasons.—As Africa is almost equally divided by the equator, by far the greater part of this continent lies between the tropics. From this situation, added to the immense arid deserts of the interior, the climate of Africa is, in general, the hottest of any part of the globe. Even the natives can scarcely endure the scorching rays of the mid-day sun; and many Europeans have, in vain, attempted to advance far beyond the coasts. The sands are so parched with the continued influence of the solar rays, that even the wind which passes over them produces effects on the skin and lungs almost equal to those of the blast of a furnace; and the scarcity of water is so great, that caravans sometimes perish from thirst, or are compelled to slaughter their camels for the small quantity of water contained in the reservoirs of those animals. Along the coasts the air is somewhat more temperate; though in the neighbourhood of the large rivers, the climate is still injurious to health. It is said, that the districts to the south of the equator are less torrid than those within the northern tropic, which is accounted for from the former being more within the influence of breezes from the sea.

Almost the whole of Africa lies in the torrid zone; and the year, as in other intra-tropical regions, is nearly equally divided between the dry and the rainy seasons. The latter is peculiarly unfavourable to the human constitution, so that during that season no expeditions of any consequence, either warlike or commercial, are undertaken.

Natural History.—The natural history of Africa is copious and interesting, and will be particularly noticed in describing the empires and kingdoms of which this continent is composed. We shall here confine ourselves to very general remarks. Among the mammalia found in Africa, the most remarkable are the Barbary and Pigmy apes, the great baboon, the rhinoceros, especially the two horned species, which is common at the Cape of Good Hope; the elephant, which is most abundant in the island of Bulama, and in South Africa; the hyena, the fennec, the lion, who appears in Africa in his greatest strength and terrors; the cat of Angora; the ichneumon, found chiefly in Egypt; the porcupine, the Madagascar squirrel, the jerboa, the hyrax; the camel, the camelopardalis, or giraffe, sometimes seen at the Cape of Good Hope; numerous species of antelopes, the Guinea sheep, the buffalo, the zebra, the quagga, the hippopotamus, or river horse, and the Ethiopian and Cape de Verd hog: it seems probable, from Mr Barrow's account, that even the unicorn, generally supposed a fabulous animal, may exist in Southern Africa.

The species of birds found in Africa are almost innumerable. We may, however, particularize the golden eagle, the ibis, the vulture, the flamingo, and the ostrich. Of these the ibis is said not to be at present met with in Egypt, though sometimes seen about the Cape of Good Hope. Of the reptiles, the most remarkable is the crocodile, a native both of Egypt and Abyssinia.

The insects found in various parts of Africa are so numerous, that a bare catalogue of those that are known would occupy a very considerable space; and every succeeding traveller, since the time of Vaillant, is continually adding to the number. Among the most extraordinary may be noticed the termes, or white ant.

Progressive Geography.—There are few subjects more interesting than the progressive geography of Africa. The knowledge which the ancients possessed of this large continent, was confined almost entirely to what is now called Northern Africa. The principal ancient divisions of Africa were, Egypt, Cyrenaica, the modern Barca, regio Syrtica, now Tripoli, Africa Propria, chiefly confined to the territories of Carthage, the modern Tunis, Numidia, now Algiers, Mauritania and Getulia, the modern Morocco and Fez. The northern part of the interior was called Lybia, and the southern Ethiopia. The idea formed by ancient geographers of the form of this continent, was, however, extremely inaccurate. They supposed that its breadth increased gradually towards the south. Of the interior almost nothing was known, though even Herodotus mentions the river Niger, and describes it as flowing towards the east.

Attempts were made, at a very early period, to improve the geographical knowledge of Africa. The earliest of these appears to have been that of the Phœnicians in the reign of Pharaoh Necho, king of Egypt, about 604 years before the Christian era. These Phœnician navigators, according to Herodotus, set out from a port in the Red sea, and passing the straits of Babelmandel, entered the southern ocean. On the approach of autumn, they landed in what Herodotus calls Lybia, where they remained for nearly a year, so as to reap corn which they had sown on their first arrival. Hence they again set out, and coasted round Africa, till, in the third year, they passed the columns of Hercules, and returned to Egypt by the Mediterranean. Much doubt is entertained with respect to the authenticity of this account of the Phœnician circumnavigation of Africa. There is only one circumstance which might induce us to believe that it really took place, viz. that it is related of these voyagers, that in the latter part of their voyage they had the sun on their right hand, which could have happened only from their crossing the equator. On the other hand, when we reflect on the imperfect state of navigation at that early period, and the difficulties and dangers which must have attended such an undertaking, we can scarcely believe it would prove successful.

Voyage of Hanno.—Posterior to this attempt of Pharaoh Necho, and some centuries before Christ, the Carthaginians fitted out a fleet, under the command of Hanno, for the purpose of exploring the western coast of Africa, and establishing a traffic with the natives. As this is the first voyage of discovery of which we have any authentic record, we shall here introduce the account of it, which was drawn up by order of the Carthaginian government, and deposited in the temple of Saturn.

The fleet consisted of sixty ships, having on board thirty thousand souls, well provided with all necessaries. After passing through the straits of Gibraltar, and sailing for two days southwards, the navigators landed, and built a city called Thymaterium, supposed to be the modern Azamor. Hence coasting towards the west, they came to the promontory of Soloeis, supposed by Major Rennel to be that now called Cantin; and having here built a temple to Neptune, they sailed half a day eastward, along a country abounding with elephants. After proceeding one day's sail to the south, they again landed, and built six towns; and again setting sail, came to a river which they called the Great River Lixus, the modern site of which is not certainly ascertained, though it is probably the Lucos, near Santa Cruz. Pursuing their voyage for one day toward the east, they came to a small island, which they called Cerne, where they staid some time. Departing hence, and sailing by a great river called Chretes, they came to what is called a lake, or large opening of the sea, in which were several islands. In this opening they sailed for the space of a day, and saw several high mountains inhabited by savage people clothed with skins. This lake or opening is, by Major Rennel, supposed to have been the mouth of the Gambia; so that if his opinion be correct, Hanno and his companions must have proceeded pretty far to the south.

Discoveries of the Moderns.—From the voyage of Hanno, nothing seems to have been done towards investigating the geography of Africa till the fourteenth century, when, in consequence of a grant from Pope Clement VI., by which the Canary islands, then little known, were bestowed on Louis de la Cerda, of the royal family of Castile, these islands became an object of serious consideration. Accordingly, about 1395, they were taken possession of by John de Betancourt, who made a pretty accurate survey of them.

In the beginning of the fifteenth century, in the reign of John I. king of Portugal, a voyage of discovery was undertaken by direction of Prince Henry, fourth son of that monarch. Hitherto the western coast of Africa had been explored only as far as Cape Non or Nun; but this expedition advanced consi-

Africa. derably to the south of that promontory, and discovered Cape Bojador. In several successive voyages, during the early part of the fifteenth century, the maritime discoveries of the Portuguese were continually extended. In 1418, the island of Porto Santo was first seen; in 1420, the island of Madeira, discovered the preceding year, was explored; in 1434, Cape Bojador was doubled; in 1446, Cape de Verd was discovered and doubled; in the following year the discoveries had reached the river Gambia, then called Rio Grande; in 1449 were discovered the islands called Azores; about 1456, the Cape de Verd islands appear to have been first noticed; in 1460 the coast of Sierra Leone was first observed; in 1471 several small islands were discovered, especially that of St Thomas; in 1480 the Portuguese navigators proceeded as far as the river Congo, or Zayre; and in 1487 our knowledge of the western coast of Africa was completed by the discovery of the Cape of Good Hope; in 1498 the intrepid Vasquez de Gama doubled the Cape of Good Hope, and examined the coast of Zanquebar; and thus, in the course of a few years, the whole outline of the African continent was completely traced.

Still the interior of the continent was scarcely known. The Portuguese merchants and missionaries from time to time published accounts of the nations on the eastern and western coasts, and the Dutch afforded considerable information respecting the country immediately contiguous to the Cape, but none of these accounts extended our knowledge a hundred miles within the country. The importance both to commerce and to science of an accurate acquaintance with the interior of Africa, at length, towards the conclusion of the eighteenth century, roused the attention, and excited the genius both of public bodies and private individuals. Abyssinia was explored by Bruce, Egypt by Volney and Sonnini, the Cape of Good Hope by Sparrman and Barrow, Madagascar by Rochou, Darfur by Browne, and Nigritia and the western nations by later travellers, of whose journies we shall now proceed to give a more minute account.

Journey of Ledyard.—In the year 1788, a society was formed at London of about ninety-five gentlemen of rank and learning, for promoting discovery in the interior parts of Africa. To this *African Association*, as it is generally called, we are indebted for much valuable information, though their laudable exertions have not been attended with all the success that could have been desired; and several gentlemen have fallen victims to their enterprising spirit, in endeavouring to execute the office assigned them by the society.

The first traveller who offered his services in prosecuting the views of the African Association, was Ledyard, an American, a man of great intrepidity and penetrating genius, who had already passed many years in travelling over various parts of Asia and Europe, and had accompanied Captain Cook in one of his voyages round the world. In consequence of a recommendation from Sir Joseph Banks, Mr Ledyard was appointed by the Association to explore the interior of Africa, from Egypt to the Niger, in the direction of Senaar, and left London, for this purpose, on the 30th of June 1788. In little more than a month, he arrived at Alexandria, in Egypt, where he procured the habit of an Egyptian traveller, with such instructions as might enable him to act up to the character he had assumed. He then repaired to Cairo, which he reached on the 19th of August; and where he remained, till, by conversing with the travelling merchants who formed the caravans that annually traverse the African deserts, he had acquired considerable knowledge of the countries through which he had to pass, and the manners and customs of their inhabitants. Before he could set out from Cairo, however, in further prosecution of his journey, he was seized with a bilious complaint, which soon put a melancholy period to his existence, and deprived the public of those services which he appeared so well qualified to perform. Africa.

From the observations made by Mr Ledyard while at Cairo, as published in the proceedings of the African Association, we collect the following particulars: The travelling merchants, or Jalebs, traffic to Senaar, Darfur, Wangara, and Abyssinia. To the first of these places, they generally carry trinkets, which they barter with the natives for elephants' teeth, gum, ostrich feathers, slaves, and camels. Much of the trade between Senaar and Cairo is carried on in the name of the king of Senaar, who is himself a merchant, and has a factor at Cairo. From Darfur, the Jalebs also bring gum, ivory, and slaves. The inhabitants of Darfur were represented to Mr Ledyard as being in the lowest state of savage society. From Wangara these merchants bring gold, with which that kingdom is said to be abundantly supplied, though the king is generally careful not to make an ostentatious display of the riches of his country, for fear of attracting the notice of his poorer neighbours. The caravans estimate the distance of places in their route by the days required to travel from one to another; and as these journies are generally performed on camels, whose ordinary rate of travelling is 20 miles per day, these distances are easily computed. Thus, from Cairo to Senaar is 30 days journey, or 600 miles; to Fezzan is 50 days, or 1000 miles; and from Fezzan to Tombuctoo is 90 days journey, or 1800 miles.

Mr Lucas.—In the same year, (1788,) the Association engaged Mr Lucas, who, after having passed three years as a slave in Morocco, had resided in that empire for 16 years in the character of British vice-consul, to explore the great desert from Tripoli to Fezzan, from which he was to return by the river Gambia on the coast of Guinea. Mr Lucas sailed from Marseilles on the 18th October 1778, and a week after landed at Tripoli. He here met with two shereefs who had brought from Fezzan slaves, senna, and other commodities. Under the protection of these shereefs, who, being descended from Mahommed, were regarded as sacred both in their person and property by the predatory tribes of the desert, he set out from Tripoli on the 1st of February 1789, provided with a good mule from the bashaw of Tripoli, and a letter of recommendation from the bey to the king of Fezzan. After passing two days and a half in travelling among dreary hills of loose sand, which was agitated by every breeze, they came to a spot in which were a few fields of corn, diversified with date and olive trees; and, on the fourth day, after a tedious march of three hours among rocky hills, they arrived at an extensive plain abounding in those fruit trees, which here grow in great luxuriance. This plain is not far from the sea coast, and near it lies the town of Lebida, where Mr Lucas saw the ruins of a Roman temple, of several triumphal arches, and a large aqueduct by which water had once been conveyed to Libida from a neighbouring hill. On the seventh day of their journey, they encountered a party of Arabs whom they suspected to be enemies, and prepared to attack them; but fortunately the Arabs and the shereefs were known to each other, and the threatened battle was exchanged for a scene of festivity. On the evening of this day, they reached Mesurata, where Mr Lucas was politely received by the governor; but finding it impossible to obtain a sufficient number of camels for the journey to Fezzan, he abandoned the journey for that season, and returned to Tripoli, from which he set out by way of Malta and Marseilles, and arrived in England on the 26th of July.

It does not appear that much information was obtained by Mr Lucas, either on his journey from Tripoli to Mesurata, or during his stay at this latter place. He observed, indeed, that the merchants of the caravan seldom encumber themselves with tents, but when they encamp for the night they unload their beasts, arrange their goods and baggage in a circle, within which they light fires, and repose themselves on mats, without any other covering than their alhaiques or blankets; and he learned from Ben Ali, a native of Morocco, some new intelligence respecting the route of caravans from Fezzan to the Niger, by the way of Bornou and Kashna.

Major Houghton.—The next adventurer who undertook to explore the interior of Africa, was Major Houghton, an officer in the British service, who had passed some time as fort-major in the African island of Goree. The African Association had received from an Arab, named Shabeni, a very interesting and extraordinary account of the empire of Houssa, adjacent to Tombuctoo, the capital of which was described as not inferior to London or Cairo in extent and population, while he represented the inhabitants as arrived at a high degree of civilization and refinement, living under the government of a limited monarchy, and the restrictions of written laws, and even possessing a considerable share of literary knowledge. For the purpose of ascertaining the truth of these surprising reports, Major Houghton was engaged by the Association; and he was instructed to proceed by the shortest route to the Niger, of which he was to ascertain the course, and, if possible, the rise and termination; to visit the cities of Tombuctoo and Houssa; and having acquired all the information in his power, he was to return by way of the desert, or by such other route as should be most convenient.

In compliance with these instructions, Major Houghton left England on the 16th of October 1790, arrived at the mouth of the Gambia on the 10th of the following November; and was hospitably received by the king of Barra, to whom he was known, and who assured him of all the assistance and protection in his power to afford. Having procured an interpreter, he sailed up the river to Junkiconda, where he purchased a horse and asses for the purpose of conveying his goods to Madina the chief town of the kingdom of Woolli. Here he arrived after a difficult and dangerous journey, and was kindly received by the king of the country; but before he left the town, his farther progress was nearly arrested by a fire which broke out in the habitation where he had fixed his residence, and consumed the greater part of his merchandize, while his interpreter ran off with his horse and most of his asses. He left Madina on the 5th of May, and pursuing a north-easterly course for five days, arrived at the frontier of the kingdom of Bondou, adjoining to Woolli. He now traversed a tract of 450 miles, till he arrived at the banks of a river called Faleme, which constitutes the south-western boundary of the kingdom of Bambouk. In consequence of a war between the king of this country and the sovereign of Bondou, the unsuccessful termination of which had compelled the former to relinquish a part of his territories, Major Houghton found himself under very unpleasant circumstances. The king of Bondou was now residing in his newly acquired possessions, and not only received our traveller in a very ungracious manner, but either authorised or permitted his son, with a body of armed men, to rob him of almost all his baggage and effects. At length he found means to escape, and was proceeding on his way to the capital of Bambouk, when he missed his road in the midst of a forest, and was compelled to pass the night on the ground, exposed to all the inclemencies of the rainy season. The consequence was a violent fever, accompanied with delirium; under which he would have sunk, but for the kindness and hospitality of a negro family, to whom he had been conducted by his guide. His reception by the King of Bambouk was flattering, and such as seemed to promise future advantages to the cause in which he was embarked. In the course of July he became acquainted with a respectable Bambouk merchant, who agreed to conduct him on horseback to Tombuctoo, and return with him to Junkiconda, for which the merchant was to receive L.150 Sterling, on their arrival at the British factory. We have no further authentic account of Major Houghton's adventures; but it was reported by the natives of Ludamar, that on arriving at Jarra, he was prevailed on by some Moorish merchants to accompany them to the salt mine of Tissheet, considerably to the north of his intended course, and it is supposed that he was either murdered by his treacherous conductors, or, after being rifled of his remaining effects, was left to perish in the woods or the desert.

Much curious information has been derived from Major Houghton's dispatches. He describes the kingdom of Woolli as a delightful country, abounding with all the necessaries and conveniencies of life, and well situated for an extensive and profitable commerce. The inhabitants of Bondou, like the Arabs, have long black hair and copper-coloured complexions, and belong to the tribe of Foulahs, who occupy the greater part of the district between the Senegal and Gambia. The inhabitants of Bambouk, again, are of the negro race, are engaged chiefly in agriculture, and have made little progress in arts and manufactures. Like almost all the other negro tribes, they are a nation of robbers.

Mr Park.—We now come to the most enterprising, and, on the whole, the most successful of the travellers who have undertaken to explore the banks of the Niger, the celebrated Mungo Park. This gentleman had just returned from India, and as the African Association were then looking out for a proper person to supply the place of Major Houghton, Mr Park eagerly offered his services, and, after some enquiry into his qualifications, his offer was accepted.

He sailed from Portsmouth on the 22d of May 1795, and arrived at Jillifree, on the north bank of the Gambia, on the 21st of the following month. Hence he proceeded to Pisania, a British factory, about 200 miles up that river. He was most kindly received by Dr Laidley, and remained for several months, collecting information respecting his intended journey, and learning the Mandingo language.

Leaving Pisania, on the 2d December 1795, and directing his course to the Niger, or Joliba, he soon found it necessary, in consequence of a war between two chiefs of the interior, to make a turn to the northward, towards the territory of the Moors; and, on the 7th March, was taken prisoner by Ali, a Moorish chieftain. After a series of unexampled hardships, he escaped, with great difficulty, in the following July; and, after wandering for three weeks through a wilderness, arrived at Sego, the chief town of the kingdom of Bambarra, situated on the banks of the Niger, and containing, by computation, about 30,000 inhabitants. Finding it would not be safe for him to remain long at Sego, he proceeded by Sansanding to Silla, a town on the south side of the Niger, about 70 or 80 miles farther down the stream. Here he found that, in his unprotected situation, there were insurmountable obstacles to his farther progress, and therefore returned up the current of the Niger, till he reached Bammakoo, on the frontiers of Bambarra, on the 23d of August. The Niger was here no longer navigable, and he was obliged to travel for several weeks on foot, in the worst of the rainy season, wandering alone, and deprived of every convenience that might alleviate his distress, through a mountainous and pathless country; and on the 16th of September arrived at Kamalia in the kingdom of Manding, situated at the foot of some rocky hills, and noted for the gold which is collected in its neighbourhood. The fatigue and hardships to which he had been exposed, brought on a severe and dangerous illness, by which he was confined for several weeks, and appears to have owed his life to the benevolent attentions of his host, a negro slave-merchant, called Karfa Taura, whose family nursed him with the kindest solicitude. He had still 500 miles to travel, chiefly through a desert country, before he could reach any friendly district on the banks of the Gambia, and no opportunity occurred that could afford any chance of accomplishing so long and perilous a journey till the month of April 1797, when he heard of a caravan of slaves who were moving to the westward. These he joined, and left Kamalia on the 19th of April. On the 3d of May they entered Malacotta, a small unwalled town, consisting of huts formed of split cane, plastered with mud. There they remained four days, and on the 12th of May crossed the river Faleme. On the 4th June they reached Madina, the capital of Woolli; and on the 10th of the same month arrived at Pisania, which he had left 18 months before. After remaining about five days, he embarked in a slave ship bound to America; and being by stress of weather driven to Antigua, he left the ship, sailed from Antigua on the 24th November, in a British vessel; and on the 22d December arrived at Falmouth, having been absent two years and seven months.

It must be confessed, that the objects for which Mr Park undertook his first journey were not completely fulfilled. He ascertained neither the origin nor the termination of the mysterious Niger, though he had ocular demonstration of the truth of the assertion made by Herodotus, that the course of this river is towards the east. He has also fixed the boundaries of several moorish and negro nations, and brought us acquainted with many interesting circumstances respecting their manners and customs. In particular, he has admirably depicted the character of the Mandingo tribes, and of those wandering hordes of Bedouin Arabs that rove through the extensive district of Ludamar. In short, he has fixed the geographical position of a great number of towns and villages on the banks of the Gambia, the Senegal, the Faleme, and the Niger; and although he was unable to ascertain the truth of the Arabian reports respecting the empires and cities on the banks of this great river, he saw and described enough to convince us that they are at least highly probable.

Mr Horneman.—Before Mr Park's return from his first journey, another gentleman had presented himself to the African Association. This was a young German, of the name of Horneman, of respectable literary attainments, of athletic form, vigorous constitution, and temperate habits; qualifications which certainly fitted him in an eminent degree for executing the arduous task he was about to undertake. He came to London in the spring of 1797, was soon appointed by the Association, and in the autumn of the same year left England for the south of France. He sailed from Marseilles in a Cyprus vessel in the month of August, and landed at Alexandria in Egypt on the 10th September. He soon left this city for Cairo, where, like his predecessor Ledyard, he passed some time waiting for the departure of the caravan for Fezzan; and acquiring such information as might assist him in his future progress. It appears that he set out for Fezzan; but as no authentic accounts have arrived of his proceedings after that period, it is to be apprehended that he has fallen a prey to the insalubrity of the climate, or the treachery and inhumanity of the natives.

Mr Park's second journey.—After the peace of Amiens, it was resolved by the British government to dispatch a mission to Africa, under their immediate authority and direction, for the purposes of ascertaining how far it might be practicable to establish a commercial intercourse, through the medium of our settlements on the Gambia, between this country and the nations that inhabit the banks of the Niger. It

Africa. is not surprising that Mr Park should have been selected as the fittest person to carry into effect this important resolution; nor, considering his enthusiastic turn of mind, it is not to be wondered at that he should eagerly embrace the offer. This offer was made in the autumn of 1803, and he came to London at the end of that year to arrange measures for his journey. In consequence, however, of the change of government which took place in May 1804, the business of the African mission was successively delayed, first till the following September, and afterwards till January 1805.

On the 30th of this month, Mr Park embarked at Portsmouth, and took his final leave of his native country, to which he was destined never to return. He was accompanied from Britain by Mr Anderson, his brother-in-law, a respectable surgeon, by Mr Scott, a draughtsman, and four ship-carpenters; and it was settled that, on his arrival at Goree, he was to be joined by a detachment of volunteers from the royal artillery. It was naturally supposed, that, protected by such a guard, our travellers would have nothing to fear from the undisciplined savages through whose country they had to pass; and indeed there is every reason to believe, that had the expedition taken place some months earlier, it would have been attended with complete success.

The Crescent transport, having on board Mr Park and his companions, touched at Porto Praya in St Jago, one of the Cape de Verd islands, on the 8th of March, for the purpose of supplying themselves with asses; and having obtained a sufficient number, they left the island on the 21st, and seven days after landed at Goree. They speedily procured their compliment of soldiers, consisting of Lieutenant Martyn and 34 privates, forming part of the garrison of Goree. By the 26th of April our little army had reached Kayee, a small town on the banks of the Gambia, from which they set out in good health and high spirits, on their eventful journey towards the Niger. It soon appeared how just had been the apprehensions which Park had frequently expressed, of undertaking this journey at such a season of the year; and it is much to be lamented that the arduous leader of the party had not delayed his final departure from the British settlements till the tropical rains and excessive heats which attended them had subsided. It would be a melancholy task to follow this devoted party in their march through the woody and mountainous districts that lie between the Gambia and the Niger. It is sufficient to observe, that, by the time they reached Sansanding on the latter river, only five out of 44 Europeans who left Goree survived. These were Mr Park, Lieutenant Martyn, and three of the soldiers. Their number had almost daily diminished from the 8th of June, when they encountered a heavy tornado near Dentila, till the 28th October, when Mr Anderson was laid in the grave. All the carpenters had died; and it was with great labour and difficulty that Mr Park, aided by one of the remaining soldiers, joined together two halves of a Bambarra canoe, so as form something like a schooner, which he denominated the Joliba.

Mr Park's death.—With this schooner and his small remaining party, one of whom was in a state of derangement, Mr Park determined to undertake a voyage down the Niger till he should reach its termination or "perish in the attempt." Unfortunately he did perish long before he reached its termination. There are no certain accounts of the particulars of this melancholy event; but it appears from the journal of his guides Isaaco and Amadou Fatouma, that the party, after leaving Sansanding on or about the 17th November, (the date of Mr Park's last dispatch,) proceeded down the Niger till they reached Yaour, in the kingdom of Houssa, near which they were attacked by the natives, and either put to death by their spears or drowned in the river. Africa.

The second journey of Park has added but little to our geographical knowledge of the interior of Africa. Sansanding, from which government received the last authentic dispatch, is several miles higher up the river than Silla, to which place the accounts of his former journey extended. Several additional circumstances are, however, to be gleaned from the journal that accompanied the last dispatch, and the most important of these we shall here notice.

The river Gambia at Kussai, nearly 300 miles above its mouth, is at least 100 yards across, and has a regular tide, rising about four inches. It swarms with crocodiles and river horses, so that 13 of the former and 3 of the latter were seen at one time. The woods in this neighbourhood abound with wild bees, and honey is of course very plentiful. At Dentila, the tree which produces the astringent drug kino, is so plentiful that they use it for smelting iron. At Shrondo and Dindikoo are gold mines, which are merely pits sunk in the earth, in a marshy soil, to the depth of 10 or 12 feet, and the gold is obtained in minute particles by washing the soil. The mountains here consist chiefly of a coarse reddish granite, but their surface is so fertile that they are cultivated to their very summits. Several of the tributary streams passed by Mr Park are very large, particularly that called Ba-fing, at Konkromo, where a canoe in which were three soldiers was upset, and the Ba-Woolima, in which the guide Isaaco was nearly killed by a crocodile. Almost through their whole journey they were continually pestered by the thievish disposition of the natives. Indeed, according to their own account, they considered the coffle "as a *dummulafong, a thing sent to be eaten:* in English, fair game for every body." The main stream of the Niger, is separated from the remote branches of the Senegal by a ridge of mountains at the south of Toriba; and a little to the east of Bammakoo, the Niger is at least a mile in breadth, and the current sets nearly five miles an hour. Nothing can be conceived more beautiful than the views of this immense river, sometimes as smooth as a mirror, sometimes ruffled with a gentle breeze, down the current of which the canoes moved, without exertion, at from five to seven miles an hour.

The town of Sansanding is not so large as Sego, containing only about 11,000 inhabitants. It has no public buildings except the mosques. There is a large square market-place; and the different articles of merchandise are exposed for sale on stalls covered with mats to shade them from the sun. The market is crowded with people from morning to night.

Africa.

The articles sold are chiefly beads, indigo, wood, ashes, cloth from Houssa and Jinnie, antimony, sulphur, rings and bracelets of copper and silver, scarlet, amber, Morocco silks, tobacco, and salt. Besides the ordinary market-places, there is a very large space appropriated to the weekly market, held every Tuesday, on which day astonishing crowds of people come from the country to purchase articles in wholesale, which they retail in the neighbouring villages.

From the experience we now possess, and from the observations of the lamented Park, there can be no doubt that it is practicable to open a commercial intercourse between the great trading cities on the banks of the Niger, and the British settlements on the Senegal and the Gambia; but for this purpose the traders must be supported by a sufficient force, and must make their expeditions during the dry season. The British government have had it long in contemplation to renew the attempt in which Park so unavoidably failed, adopting such measures of prudence as shall, so far as human exertion is concerned, ensure success; and according to this system of precaution a mission has been appointed, and is now (November 1815) about to depart for the coast of Africa.

Before concluding this sketch of the discoveries in this extensive continent, we must notice the mission of Messrs Trutter and Somerville from the Cape of Good Hope in 1801 and 1802, the travels of Dr Lichtenstein, a German, at a later period, and the missionary journey of Mr Campbell, of a still more recent date; from all of whom much curious and interesting information, relative to Southern Africa, has been obtained. These travellers explored a considerable extent of country, and between the 20th and 28th degree of south latitude discovered a very populous region, inhabited by a tribe called Boshuanas, who have made some progress in civilization and the arts of life, and reside in villages and towns of no trifling magnitude. Leetakoo, or Latakoo, the capital of the Matchappin tribe, contains from 10 to 15,000 inhabitants. Agriculture is an object of assiduous attention in this part of Africa, and has made such advances, that corn and bean crops are successfully raised in inclosed fields. Southward from Leetakoo, are the Wanketzens, who are described as a more numerous tribe, have reached higher degrees of perfection in agriculture, live in larger towns, and are not meanly skilled in the manufacture of arms and other works in iron.

Aga || Agamemnon

AFRICAN COMPANY. See COMPANY.

AFRICAN INSTITUTION. See INSTITUTION.

AGA, a title of distinction among the Turks; as, the *aga*, or commander of the janizaries; the *spahiclar aga*, or general of the horse; and the *agas*, or chief officers of the seraglio. The principal officers of the khan of Tartary, and the governors of towns and garrisons among the Algerines, are distinguished by the same title.

AGADEZ, a region in the interior of Africa, situated in the eastern part of the Great Desert, of which the northern district is a barren sandy waste; the southern contains rich pastures, is fruitful in corn, and abounds with cattle. Three towns of this district are considerable for their wealth and population. Agad, the capital, is placed between two lofty mountains, near the source of a stream which falls into the Niger. It is surrounded with walls, and the houses are built in the Moorish style. The natives of the country resemble the wandering Arabs in their mode of life, and have some trade in manna and senna. Agad is situated in N. Lat. 20. 15. E. Long. 13. 14.

AGALMATOLITE, or Figure Stone, a species of mineral belonging to the Magnesian genus. See MINERALOGY.

AGAMEMNON, king of Argos, and the celebrated commander of the Greeks in the Trojan war. Agamemnon drove Thyestes, and his son Ægisthus, from the government of Argos, which they had usurped; and having ascended the throne, married Clytemnestra, daughter of Tyndarus, king of Sparta. As Agamemnon was the most powerful prince in Greece, he equipped the greatest number of ships and men for the expedition against Troy; and, during that famous siege, his courage, prudence, and perseverance were always conspicuous. After its fall, the prophetess Cassandra, the daughter of Priam, became the prize of Agamemnon; and by her he was warned against returning to Mycenae, on account of the plot which was formed against his life; but he disregarded the advice, and was basely murdered by his wife and her lover Ægisthus, who, during his absence, had seized the throne of Argos.

Aganippe || Agaric.

AGANIPPE, a fountain of Mount Helicon, sacred to the muses, and celebrated by ancient poets; and hence Aganippides is one of the designations of the muses.

AGAPANTHUS, signifying love-flower, a genus of plants belonging to the class Hexandria.

AGAPE, from the Greek word which signifies *love*; the love-feast or feast of charity which was instituted among the primitive Christians, and was provided by the rich to supply the necessities of the poor. It is said that the feast of love was established when the practice of having all things in common ceased. This festival was held after the service of the church ended, and also at the time of the celebration of the Lord's supper. But, about the end of the fourth century, the licentious abuses which had crept into the institution, required the interference of the council of Carthage, and occasioned a direct prohibition of its observance in churches. Among certain religious denominations, as the Baptists and Glassites, feasts of a similar nature exist at the present day, and are conducted with great propriety and decorum.

AGAPETÆ, the denomination of certain widows and virgins, who, from motives of piety and charity, attended ecclesiastics, and aided them in their functions in the early times of the Christian church.

AGARIC, Mineral, a carbonate of lime found in the fissures of rocks. See MINERALOGY.

AGARICUS, or Agaric, a genus of plants belonging to the class Cryptogamia.

AGATE, a mineral composed chiefly of jasper and calcedony, with some other simple minerals, usually disposed in concentric layers. See Mineralogy.

Agate, is also the name of an antique gem, on which are engraven representations of events relative to ancient history and mythology. Some of these gems are beautifully executed, have been preserved with great care, and are still held in high estimation.

AGATHOCLES, the tyrant of Sicily, holds a conspicuous place in history, on account of the eventful scenes of his varied life. He is described as the son of a potter, and was born 361 years before the Christian era. After a succession of adventures, in which he appeared in the character of a common soldier, a robber, and a pirate, as suited his necessities, or accorded with his bold designs, he rose to the high rank of commander in chief of the army of Syracuse. The death of Timoleon, through whose vigorous measures the expulsion of the tyrants, and the restoration of the liberty of the Sicilians had been accomplished, opened the path of ambition to Agathocles, who now aspired at sovereign authority. But he was not permitted to assume the reins of government till he came under a solemn engagement to preserve its democratic form unimpaired. With supreme power in his hands, the obligation of an oath proved a feeble restraint on the cruelty of an unprincipled ruler. Four thousand of the nobles and principal citizens, who were not disposed to acknowledge the absolute authority which he assumed, fell victims to his barbarity and ambition. The Carthaginians, who at this time held part of the Sicilian territory, became jealous of his power, declared war against him, and, after a successful engagement in the field, drove him within the walls of the city. But while he was deserted by his allies, and harassed with all the privations and miseries of a siege, his spirit remained unbroken, and turned for aid to new and extraordinary resources. He planned and executed one of the boldest manoeuvres of which the annals of history furnish any record. He assigned the command of Syracuse to his brother, transported an army to Africa, burnt his fleet, and ravaged the territory of the Carthaginians to the very walls of their city. After this success he was recalled to Sicily; but during his absence the fortune of war had changed. His army, weakened by desertion and repeated skirmishes, was driven from its strong holds; and the return and exertions of Agathocles left him no hope of retrieving his affairs. Like a celebrated modern leader and usurper, his own personal safety became his only concern in the day of disaster. With a small train of attendants, he retired to Syracuse, and abandoned his army, and even his own family, to the mercy of the enemy. The army, enraged at the baseness of his treachery, murdered his children, and surrendered to the Carthaginians. But Agathocles was not slow in satiating his revenge, for he put to death all the relations of the soldiers whom he could discover; soon after met his own fate by poison, which was secretly administered by the influence of his own grandson; and, after a reign of 28 years, terminated a life stained with cruelty and crime, by a painful death.

AGATHOPHYLLUM, a genus of plants belonging to the class Dodecandria.

AGAVE, or American Aloe, a genus of plants belonging to the class Hexandria.

AGDE, a small town in the department of Herault, in France, is situated on the banks of a river from which the department takes its name, about a mile from its junction with the sea in the gulf of Lyons. The town enjoys some trade, and is a great resort of pilgrims; and the surrounding country, which is a basaltic region, produces fine wool and silk, and is fertile in corn, wine, and oil.

AGE, in its most general acceptation, denotes either the whole period or a portion of the time of the existence of any being. The same term sometimes marks the period of thirty years, and then it seems to be synonymous with *generation*, and sometimes it is equivalent to the period of a hundred years, or a *century*. The duration of the world has been divided by historians into different ages; and the beautiful fiction of the ancient poets, which divides the progressive history of mankind into the ages of gold, silver, brass, and iron, is expressive of the state of innocence and purity, the decline and degeneracy of the human race.

AGEN, a city of the province of Agenois, and in the department of Lot and Garonne in France, contains a population of nearly 11,000, is chiefly remarkable for the venerable remains of Roman antiquity, and is 520 miles south-west from Paris.

AGENOIS, a province of France, forming part of the department of Lot and Garonne. Great part of the valley through which the rivers Lot and Garonne flow, is rich and fertile in corn, wine, and fruits, and the number of inhabitants in the province amounts to 353,000.

AGERATUM, Base Hemp, Agrimony, a genus of plants belonging to the class Syngenesia.

AGESILAUS, king of Sparta, and a celebrated military commander, was born about 444 years before the Christian era, and was raised to the throne in preference to his nephew, the son of an elder brother. The invasion of the Greek cities in Asia by the Persians, roused the Lacedemonians to arm in their own defence, Agesilaus was appointed commander, obtained some signal victories, and finally defeated Tissaphernes, the Persian general. The bravery and success of Agesilaus in this expedition obtained for him the supreme command, by sea and land, from the Spartan government; an extent of authority which no individual had before enjoyed. An interview which took place between Agesilaus and the Persian governor of Phrygia, a person of illustrious rank, presents a striking contrast between the simple manners of the former, and the luxurious habits of the latter. Agesilaus seated himself on the grass, under the shade of a tree, while, with all the pomp of eastern magnificence, rich carpets were spread for the Persian ruler, who, struck with the simplicity of a prince of such distinguished valour, relinquished for a time the splendour of rank, placed himself on the grass by his side, and entered into a close friendship.

Agesilaus was recalled to take the field against the combined forces of the Athenians and Thebans. He was wounded in an engagement on the plains of Cheronæa, and, failing in an attempt on Corinth, ravaged the surrounding country. The wanton acts of aggression in which the Spartans had indulged on their defenceless neighbours, produced a powerful combination against that people; and the Thebans, under their celebrated general Epaminondas, defeated them under the command of Agesilaus, first at the famous battle of Leuctra, and afterwards at Mantinæa.

The last exploit of Agesilaus was an expedition to Egypt, to support a competitor for the throne of that ancient country. Anticipating from the warlike reputation of the Spartan leader, to be gratified with the sight of a person of impressive appearance, the Egyptians were astonished and disappointed to see an old man, of diminutive stature, in a homely garb, sitting on the sea shore. A personal affront which he had received from the competitor whose interests he had first espoused, induced him to throw his influence into the opposite scale; and thus the king of Sparta, a small Grecian state, at the head of his army, became the arbiter of the fate of the mighty kingdom of Egypt. Agesilaus, in his voyage home, was driven into a port on the coast of Africa, where he died, in the 42d year of his reign, and the 84th of his age.

AGGERHUYS, the richest diocese of Norway, has a population which exceeds 215,000 souls, and is the residence of the chief governor of the kingdom. A fortress and city of Norway are also distinguished by the same name.

AGGLUTINANTS, an old term in medicine, applied to such substances as were supposed, according to a justly exploded theory, to have the property of healing wounds, or of uniting separate parts.

AGGREGATE, is a term applied to such flowers as are composed of florets included within the same receptacle or calyx; as dandelion, the common daisy, &c.

AGHRIM, a small village in the county of Galway in Ireland, thirty-two miles distant from Dublin, and celebrated by the total defeat of the army of James II. consisting of 25,000 foot and horse, 7000 of whom, with their general, M. St Ruth, perished on the field of battle, and the army of King William, composed of 18,000 men, under the command of General Ginkle, whose loss is stated at 600 men.

AGIMERE, an extensive region of the East Indies, stretching 5000 miles along the eastern banks of the river Indus, and varying in breadth from 60 to 150 miles. It is divided into different districts; and Agimere, the capital of the country, situated in a delightful valley, encompassed by mountains, is described as six miles in circumference, protected by walls and a strong fortress, and in N. Lat. 26. 24. E. Long. 75. 20.

AGINCOURT, a small village in the French Netherlands, celebrated in history on account of the victory gained in 1415, over the French, by Henry V. of England, who, in support of his claim on the French crown, had conducted an army of 24,000 foot, and 8000 men at arms, to France, and after a desperate resistance, became master of Harfleur; but his army was greatly weakened and diminished in numbers; and having sent back his transports on his first landing, no alternative remained but to march to Calais in the face of an opposing army of 100,000 men. The small band of the English, scarcely amounting to 10,000 men, offered a feeble resistance to such an overwhelming force. Henry, it is said, apprehensive of his critical situation, offered to resign his conquest on condition of being permitted to return to England unmolested. But the French commander, confident of an easy victory, haughtily rejected the proposal. When the English advanced to the village of Agincourt on the 24th of October, the French army was so posted that an engagement was unavoidable. Next morning, by day-light, the battle commenced with a furious onset. The conflict became dreadful, by the desperate valour of the English, and the disorder which soon prevailed in the crowded ranks of the enemy. The French lost 10,000 men on the field of battle, among whom was the Duke d'Alençon, the commander in chief, with many persons of the most illustrious rank; and 14,000 prisoners fell into the hands of the victorious army, of which, it is said, not more than 40 men perished in the engagement.

AGIO, derived from the Italian, and signifying *aid*, is a term used in commerce, to denote the difference between the value of bank money and the current coin. The agio in Holland was formerly at three or four per cent.; at Venice 20 per cent; at Genoa 15 or 16 per cent.; and at Hamburgh 14 per cent.

AGNANO, a lake near Pozzuoli, to the westward of Naples, and about two miles in circumference. The sides and bottom of the cavity of this lake are interspersed with fragments of lava and pumicestone, and it has the shape of an inverted funnel, from which it is inferred that it is the crater or mouth of an extinct volcano. The waters of this lake abound with tenches and frogs, and numerous flocks of ducks swim on its surface.

AGNATE, a term used in law to denote any male relation by the father's side.

AGNES, St. one of the Scilly islands, on the western coast of England; is of small extent, but is well cultivated, and fertile in corn and grass. On the most elevated part of the island, a lighthouse, constructed of stone, and 51 feet in height, is erected. The inhabitants do not exceed 50 families. N. Lat. 49. 56. W. Long. 6. 46.

AGNESI, Maria Gaetana, a lady of extraordinary talents and acquirements, and particularly distinguished by her mathematical learning, was born at Milan in 1718. Her father, a man of some rank, gave every facility to the improvement of a mind, which, from her earliest years, afforded remarkable indications of powerful talents. She made rapid progress in the acquisition of languages. In her ninth year she delivered a Latin oration, before an assembly of learned men, which met at her father's house, to prove that literary studies are not inconsistent with the female character. In her eleventh year, she not only read, but spoke Greek with ease and fluency; she had also acquired some knowledge of the oriental languages, and was quite familiar with French and German. But her studies were

Agnesi. not limited to literature alone. Mathematics, Natural Philosophy, and even metaphysical discussions, fell equally within the grasp of this intellectual prodigy.

While in her 15th year, she maintained *theses* on various subjects of philosophical speculation with the learned persons who at stated times assembled at her father's house, and also occasionally with learned foreigners, discoursing with them in the language in which she was addressed. It is little to be wondered at, that a young lady, in the bloom of youth, of an agreeable person and graceful manners, exhibiting all the profundity of knowledge, acuteness of observation, and power of argument of the maturest and most experienced age, should be the object of universal admiration. For the period of three years she held the most conspicuous place in these philosophical discussions; but she seems to have exercised her wonderful talents in this public manner more to indulge her father's vanity in enjoying the reflected glory of her reputation, than to gratify her own ambition for learned fame. The last splendid display of her argumentative powers took place in 1738, in presence of a numerous assembly of the most illustrious persons for rank and learning, when she finally retired from the field of disputation; and the subjects of extemporary discussions, in which she had been engaged, appeared in a quarto volume, and were published in the same year.

The vigorous mind of Agnesi was now wholly occupied with mathematical studies; and she had not long entered on the pursuit, when she composed a commentary on the Conic Sections of de l'Hospital. But she carried her researches into the higher departments of the science, and afforded ample proof of her profound skill in the doctrine of the modern calculus, by publishing, in 1748, in two 4to volumes, *Analytical Institutions for the Use of the Italian Youth*, a work of great merit, exhibiting a most perspicuous view of the subject, and still regarded as an excellent introduction to the works of the continental mathematicians. This work was translated into English, many years ago, by the late Mr Colson, professor of mathematics at Cambridge. The manuscript was discovered among the papers of the ingenious translator, by the industry of Baron Maseres, in 1801, through whose liberality it was presented to the world. This remarkable production procured for its author the honour of being elected a member of the Institute of Sciences at Bologna, and the distinguished nomination of Professor of Mathematics and Natural Philosophy in that university; an appointment which she received from the Pope. A doubt has been expressed, whether she ever entered on the active duties of the professorship; but it seems probable that it was altogether intended as an honorary mark of distinction. We are gravely told, indeed, by some of the biographers of this wonderful lady, that female professors were by no means uncommon in Italy; and one, throwing aside all the delicacy of the sex, filled the anatomical chair in the same university. The most careful inquiry, we suspect, could produce but a scanty list of female teachers; and of such professors as Agnesi, she yet remains, perhaps, a solitary instance.

Agnus || Agra.

But the well-merited honours of learned reputation faded before her; worldly distinctions lost their charms; and the desire to spend her remaining years in the exercises of devotion, induced her to retire to the gloom of a convent. She became a member of the order of Blue Nuns; exchanged the pursuits of abstract science for the study of the scriptures in the original tongue, and the ancient fathers of the church; and lived in such rigid seclusion, that the most urgent solicitations of learned foreigners, to see and converse with so extraordinary a person, were altogether fruitless. The last 40 years of her long life were devoted to religious retirement; and she died in 1799, at the age of eighty.

In the opinion of certain critics, this lady affords a striking vindication of the intellectual capacity of her sex, and an ample refutation of the degrading notion of the inferiority of the female mind. But it seems to be forgotten, that such extraordinary endowments and splendid attainments are of rare occurrence; and with all the advantages of education, the talents and acquirements of Agnesi are but seldom equalled even among the other sex. The comprehensive genius of Newton is not to be considered as the common measure of mental perfection; and perhaps the only parallel of the Italian female philosopher, recorded in history, is Hypatia, of Alexandria, who lived in the 4th century, and who, it is curious to observe, was also a mathematician, a commentator, and a professor. But although we do not allege that the female mind is unequal to scientific researches, nor do we assert that they are inconsistent with the female character, yet it may be fairly doubted whether such avocations be at all compatible with the domestic duties of wives or mothers.

AGNUS DEI, or *Lamb of God*, is a cake of wax, on which is impressed the figure of a lamb supporting the banner of the cross. This cake, having received the Pope's consecration, is distributed to the people, who ascribe to it numerous virtues, and believe that those who have it in their possession are protected from evil and prompted to do good.

AGOWS, a people of Abyssinia, who, although possessing a country abounding in the necessaries of life, are reduced by oppressive burdens to great poverty and wretchedness. The Agows seem to be a pastoral people; the care of their cattle, and the management of bees for the honey and wax, are their chief occupations. Hides, tanned in a peculiar manner, constitute their only dress; and in religion, manners, and customs, they approach nearly to the other nations of Abyssinia.

AGRA, a very extensive province of Hindostan, having Delhi on its northern boundary, and the province of Oude on the east. The productions of Agra are, rice, cotton, and indigo, which is esteemed the best in the east, with all the fine fruits of tropical climates; and its chief manufactures are muslins, silk stuffs, and gold and silver lace. The revenue of this province exceeds 16,000,000 rupees; and its military force is composed of nearly 600,000 infantry, 50,000 cavalry, and more than 200 elephants.

AGRA, the capital of the province of the same name in Hindostan, is situated on the river Jumnah, 300 miles to the eastward of Surat. Agra became the seat of empire in the time of Akbar. From an inconsiderable place, it gradually rose to wealth and splendour; and towards the close of the long reigns of that emperor, and of his son and successor, it was justly regarded as the most magnificent city in the east. The city is built in the form of a crescent, and surrounded by a stone wall, and a ditch of a hundred feet wide. The streets are narrow and irregular, with low and mean houses; but the palace and castle are remarkable edifices for extent and grandeur. The palace, which was erected at an expence of three millions of rupees, and employed a thousand men for twelve years, is situated within the castle, contains three courts, is encompassed with splendid porticoes and galleries, finely painted and gilt, and affords accommodation to the imperial guards and their officers. The spacious and magnificent apartments of the emperor and his seraglio appear in the third court of this vast structure. The grandeur and magnificence of Agra are increased by eight hundred public baths, sixty caravanserays or lodging-houses, and numerous mosques and sepulchral monuments, among which the mausoleum of Akbar is not the least conspicuous, as well as another erected to an empress, which cost £75,000 Sterling. N. Lat. 27. 15. E. Long. 78. 29.

AGRARIAN LAWS, from a word which signifies a field, are those laws which were enacted at Rome to regulate the division of the conquered lands, and to limit the extent to be held by each person. The most celebrated of these laws was promulgated by Spurius Cassius, about the year of Rome 268. Many laws of this description were passed at different periods, and they referred to the partition not only of the territory taken from the enemy, but also of lands purchased with the public money, or of such as had been usurped by powerful individuals. Many of the attempts to introduce and establish Agrarian laws excited, as might be expected, great dissension between the Roman people and their magistrates, and frequently terminated in violent commotions.

AGRICOLA, Cneius Julius, one of the most celebrated of the Roman generals who conducted the war in Britain, and contributed to its subjugation to the Roman power, was born in the year 40, in Provence, studied philosophy and law at Marseilles, and afterwards served in a subordinate capacity in the Roman armies in Britain. His return to Rome was immediately succeeded by an appointment to the quæstorship of Asia, during which his conduct was greatly distinguished by honour and integrity. Agricola supported Vespasian when he assumed the imperial power and dignity, was himself raised to patrician rank, and was appointed governor of Aquitania. After the lapse of three years he returned to Rome, and was admitted to the consulship along with Domitian, and in the year 78 was elevated to the important station of governor of Britain; and in the affairs of this country, the prudence, address, and vigour of Agricola's administration were soon highly conspicuous. Having suppressed several revolts, and terminated successfully different campaigns in which he had engaged, he wisely attempted, by conciliatory measures, to secure the conquests which he had made; and the schemes which he proposed to a certain extent succeeded. Civilization made some progress among the Britons. They adopted the customs, imitated the manners, assumed the dress, and studied the language of the Romans. The cessation of hostilities was favourable to the arts; and during this period of tranquillity, many of the splendid works of the Romans in Britain were erected. Baths, temples, and other magnificent edifices arose, to adorn the rugged aspect of the country. But this was only a temporary calm; the Britons were yet unacquainted with peaceful habits, or their love of liberty and independence would not suffer them to submit quietly to a foreign yoke; and Agricola resuming offensive operations, proceeded northward in his career of victory.

In the third campaign in Britain he advanced to the river Tweed; in the next he subdued the whole region between the Tweed and the Forth; and in the fifth he crossed the Forth, and carried his victorious arms into countries hitherto unknown to the Romans. Having proceeded beyond the Tay in his sixth campaign, in the following spring he advanced with an army of 11,000 men towards the Grampian mountains, to attack the Caledonians, amounting to 30,000, under Galgacus, an able general. The battle was severe and bloody; and the Caledonians, after leaving 10,000 dead on the field, were completely routed, and their country was reduced to a desolate waste.

Domitian, who had now attained the sovereignty of the empire, although he encouraged the triumph which was decreed to Agricola, and ordered a statue to be erected to his honour, on account of the splendid acquisitions which he had made to the Roman territory, became jealous of his glory and popularity, and recalled him from Britain, under the false promise of promotion to the government of Syria. But the promise was studiously evaded; and Agricola was no longer permitted to hold any place of trust and authority. He died soon after his retirement from public life; and his death was ascribed to poison, administered, according to a prevailing suspicion, at the instigation of the emperor. Tacitus, the celebrated historian, who married the daughter of Agricola, has transmitted to posterity a highly interesting biographical sketch of his father-in-law; and while classical taste remains, and elegant composition is admired, the memory of Agricola will not be forgotten. The glow of affection which his virtues excited while living, and the tender effusions of mournful regret occasioned by his death, have produced one of the finest specimens of pathetic expression.

Agricola, George, a physician and mineralogist, was born at Glauchen, in Meissen, or Misnia, in Germany, in 1494, received his medical education in Italy, and entered on the practice of his profession in his native country. Accompanying the train of some German princes in the expedition of Charles V. into Bohemia, he seems to have imbibed a strong desire to acquire a knowledge of minerals and metallurgical operations, which continued to be his favourite pursuit, and afterwards his sole study, through life. Having relinquished the medical pro-

Agricola.

fession, he removed to the celebrated mining district of Chemnitz, where he not only devoted his whole attention to the prosecution of mineralogy, but spent his patrimonial property, as well as the pension which he enjoyed from the German princes, in the ardent pursuit of the same object. Agricola is generally supposed to be the first German author who professedly wrote on minerals; and his works on this and kindred subjects are not destitute of elegance and ease of expression. His writings, composed in Latin, treat of the *Origin and Causes of Subterranean Matters;* of the *Nature of Fossils;* of *Mineral Springs;* of *Metallic Matters,* &c.

At one period of his life, it is said, Agricola was inclined to the Protestant religion; but he died steady in the faith of the church of Rome. His death happened at Chemnitz in 1555; and so violent was the bigotry of the Lutherans, against whom it was alleged he had at one time uttered severe censures, that his body remained unburied for five days. It was afterwards removed to Zeits, and consigned to the grave in the principal church.

AGRICULTURE.

Introduction

AGRICULTURE, in its strict acceptation, signifies the cultivation of the ground, for the improvement and increased production of such vegetables as are employed directly for the support of man, or for the nourishment of those animals which are destined for the purpose of food or domestic labour; but, in a more enlarged sense, it includes the whole business of *Husbandry,* or whatever is connected with *Rural Economy.*

The principles of agriculture and gardening may be regarded as nearly the same. The object of both is the culture of certain vegetable productions in the greatest abundance and in the utmost perfection of which they are susceptible. But the former proceeds on a large scale, and is employed in rearing plants of a hardy nature, while the latter is occupied with the cultivation of more delicate vegetables, which require more minute attention and nicer management. The industry and ingenuity of the Chinese, in their more populous provinces, where land is greatly subdivided and held in small possessions, have carried agriculture to a state of perfection which is not far distant from that of gardening in some other countries.

To prove the importance of husbandry, it is scarcely necessary to refer to ancient nations, who ascribed divine honours to those to whom they conceived themselves indebted for the invention or discovery of different branches of the art. The kings of ancient Persia, once every month, laid aside the pomp and grandeur of state, and relinquishing the luxurious banquet to partake of the simple fare of the husbandman, afforded a striking expression of the high estimation in which it was held by that people; and, in modern times, a practice somewhat similar prevails among the Chinese; the monarch, as it were, divests himself of his imperial dignity, condescends annually, in the commencement of spring, to put his hand to the plough, and offers a solemn sacrifice to secure a favourable season and an abundant crop.

With that prepossession which a favourite subject on which the mind has long dwelt usually inspires, some writers who have assigned to agriculture an extraordinary pre-eminence over other arts, seem to have left altogether out of view the intimate connection and mutual relation which subsist among all the branches of human industry. Without the aid of mechanical ingenuity, what progress could agriculture make towards improvement? Without the plough and the spade, the operations of the husbandman would be clumsy and awkward. Mechanical contrivances are not less essential to the successful advancement of agriculture, than bread-corn is a necessary requisite to the manufacturer and artizan. It is needless to dilate on this topic; a very slight consideration must render it obvious, that the arts of life are not to be contemplated in an independent or insulated state, for they mutually cherish and support each other. No profession could be long exercised without its proper objects. The labours of the husbandman would soon cease, if the productions of the soil found no market, or could not be commuted with the industry of those engaged in the multiplied processes of arts and manufactures. But laying aside this fancied rank, this presumed antiquity and preference, when the profession of husbandry has attained some degree of perfection, such as it exists in Britain at the present day, if we consider the extent of intelligence, the varied knowledge, the accurate discrimination, the unwearied industry, the minute details, and the economical management which its successful practice requires, it cannot fail to occupy a high place in our estimation.

History.

We shall not attempt to trace the history of agriculture among ancient nations. The works of Hesiod and Xenophon on the husbandry of the Greeks are yet extant; various Roman authors, as Cato, Varro, Columella, Pliny, and others, have treated largely of the same subject; and none, who is at all acquainted with classical literature, can be ignorant that the beautiful poem, the Georgics of Virgil, is devoted to the illustration of the different branches of rural economy. Aware of the importance of agriculture in a state, the Romans were greatly distinguished by their knowledge and industry in this pursuit; and it is not a little curious to remark, that modern husbandry has added only two plants, the potatoe and buck-wheat, to the number of species, amounting to forty or forty-three, which were cultivated by that people.

The state of agriculture in Britain, previously to the Roman invasion, was extremely rude. But as the Romans never neglected to introduce their own improvements into the countries which became subject to their dominion, the agriculture of Britain flourished greatly under their knowledge and experience of the art; and the produce of corn was so abundant, that large quantities were exported. It is said that

History.

800 vessels, each supposed equal to 300 quarters, were employed in the export trade of corn.

The progress of agricultural improvement in Britain was interrupted by the inroads of the Saxons, a rude people, and chiefly devoted to a pastoral life. The native inhabitants were driven from the lowlands, and took refuge in the mountainous districts of Wales. But the limited possessions and increasing population of the new settlers, required them also to direct their attention to tillage, for the purpose of raising corn. The Norman conquest, in the year 1066, proved another serious interruption to the progress of agriculture as it existed in Britain at that period. The invaders introduced their own husbandry; and it appears, from the description of William of Malmsbury, that the vine was successfully cultivated, and extensive vineyards established in the vale of Gloucester, from which wine little inferior to the wines of France was produced.

In several succeeding centuries, the numerous religious houses which arose in this country were richly endowed by pious donations, and acquired those vast possessions, which included many of the most fertile spots in the kingdom. With whatever indolence and luxury the monkish proprietors may be charged, they were not inattentive to husbandry. They introduced and cultivated some of the best fruits, planted the finest orchards, the remains of some of which are objects of admiration at the present day, and, with great humanity and moderation, exercised a paternal care over their farmers and tenants, altogether worthy of patriarchal times.

Agriculture was greatly interrupted and depressed during the severe struggle for power between the houses of York and Lancaster which deluged England with the blood of her citizens. It revived in the time of Henry VIII., and the first English writer on this subject appeared in his reign. This was Fitzherbert, one of the judges of the court of Common Pleas, who published, in 1534, *The Book of Husbandry;* and, in 1539, *The Book of Surveying and Improvements.* In some succeeding reigns it was checked by injudicious and oppressive laws. But it was encouraged and promoted during the Protectorship of Cromwell; and the writings of Gabriel Plattes and Walter Blythe seemed to have contributed not a little to its improvement. About the same period Samuel Hartlib, the friend and contemporary of Milton, appeared as a writer on agriculture; and the hint thrown out in the preface to his work, entitled the *Legacy*, in which he regrets the want of a public establishment for the improvement of husbandry, procured for him, it is said, a pension of L. 100 a-year from the Protector.

The writings of Evelyn on *Earth*, or Soil, and *Plantations*, subjects closely allied to agriculture, contributed to its improvement; and the celebrated work, published in 1713, by Jethro Tull, the father of the horse-hoed or drill-husbandry, forms a remarkable era in its progress, and confers a singular benefit on the art by the introduction of so valuable a practice, although the author carried his speculations much too far when he fancied that his system would supersede the application of fertilizing substances, or the use of manures to an exhausted soil.

History.

The dawn of still higher degrees of agricultural improvement in Britain, began to appear about the commencement, but its brighter day did not break forth till towards the close of the eighteenth century. During this period, the spirited exertions of some of the first noblemen and gentlemen, who had formed themselves into a society for the advancement of internal economy, introduced a better system of husbandry in many districts of the northern part of the kingdom; under the fostering care of the Dublin society, a powerful, liberal, and enlightened body, the state of rural economy has been greatly meliorated in Ireland, whose genial climate and rich soil are peculiarly favourable to every judicious improvement in husbandry; and the British Board of Agriculture, established about 1794, by the zeal and patriotism of Sir John Sinclair, baronet, has been the means of amassing a most valuable collection of information on all branches of rural affairs from every district of the United Kingdom.

The institution of the agricultural professorship in the university of Edinburgh, and the fortunate appointment of Dr Coventry, whose numerous scientific acquirements so eminently qualify him to fill that chair, may be regarded as an important era in the history of the rural economy of this country. With the happy talent of deducing, from extensive and accurate observation, precise and rational rules of practice, that enlightened professor, not only by his valuable public lectures, but also by the judicious system of management in every department of husbandry, which, at his suggestion and recommendation, have been adopted by individuals, must soon have the high gratification of witnessing the beneficial effects of his excellent instructions rapidly and widely diffused throughout the nation.

In closing this historical view of the progress of agriculture, we must not omit noticing the writings of Anderson, Young, Marshall, the numerous reports of its present state in counties and districts, chiefly drawn up by intelligent practical farmers, and the essential services which they have contributed to its improvement in their ample illustrations of its various branches; and also the provincial societies, of which scarcely a district of the kingdom is without one, by whose influence, in the frequent communications among the members themselves, and the occasional publication of memoirs, read and discussed at their stated meetings, in different periodical works, agricultural knowledge has been in no small degree promoted. A liberal spirit of communication is a distinguishing feature in the character of the British agriculturist. No concealment, no secrecy, no mystery, as in other arts, appears in his profession. With the most unreserved confidence, he submits all his plans, and operations, and discoveries, however beneficial to himself, to the inspection and examination of his countrymen, and, with the most laudable zeal, he hastens to make them known to the world.

Objects of Agriculture.—We have already hinted at the variety of information requisite for the successful practice of agriculture. An accurate knowledge of the climate, including the variations of temperature and pressure of the atmosphere, the prevailing winds, the quantity of dew, rain, and snow, and the changes of the seasons, may often regulate the proper branch of husbandry which is adapted to particular situations. This kind of knowledge is undoubtedly of great importance, and merits the attentive consideration of husbandmen. But as the method of observing and recording these phenomena, will be fully treated under METEOROLOGY, we must avoid repetition, and omit it in this place. The objects which come under discussion in a system of agriculture, may be enumerated under the heads of Draining—Inclosures—Soils—Manures—Implements of Husbandry—Tillage—Grass-lands—Live-stock; and topics of a miscellaneous nature—as the accommodation in Dwelling-houses and Offices—Leases—Rent.

CHAP. I. OF DRAINING.

To whatever purpose land is destined, whether for tillage or pasture, when water, as it falls in the form of rain and collects on the surface, or as it arises from springs in the bowels of the earth, stagnates upon it for any length of time, it becomes comparatively of little value. Even the temporary stagnation of water on arable land may interrupt the necessary operations of tillage in their proper season, and occasion a scanty crop and a precarious harvest; while it may give rise to those diseases which are induced by a wet soil and a moist atmosphere. The produce of grass lands, also, in which water is redundant, is herbage of a coarser and hardier kind; hence it must appear, that draining is the first and one of the most important improvements in husbandry: The processes for the management of arable lands are rendered more seasonable and certain, the herbage crops change their character and afford more nourishing pasture, and the climate itself is essentially improved.

SECT. I. *Of Surface Draining.*

The drainage of fields, or inclosures of moderate size, is effected by means of the ordinary furrows which are formed in the operations of tillage; and the ditches which usually surround such inclosures, and receive the superabundant water from the furrows, are the main drains. In subdividing and inclosing land, this important object should be always kept in view; for the limits may be fixed in such a way, as at the same time to accomplish the valuable purpose of draining. But in extensive flats which are covered with water during the whole or great part of the year, a more expensive operation is required. A main drain conducted from the intended outlet, must be formed with such a slope, and of such a depth, as shall be sufficient to relieve the soil from all redundant water. The course of a drain of this description, when the inclination of the ground is not perceptible, is found by the ordinary process of levelling, and in most cases by the use of the spirit-level alone. But, without any instrument, those who are familiar with practical draining, can discover the declivity of the ground and the course of the water, even in land which seems nearly flat, by examining the ditches when they are almost dry in summer, and by observing to what point the leaves of aquatic plants are directed. When the extent of land to be freed from water is considerable, a single drain is seldom sufficient; branches from different parts of the field uniting with the main drain are necessary; and the number and direction of these branches must be determined by the extent and inequalities of the surface. The subordinate drains or branches should form the junction with the main drain in the direction of the current, to avoid the danger of sand or earth accumulating and forming obstructions when they enter it transversely.

The declivity of the ground in many cases regulates the slope of drains; but where the outlet and other circumstances afford an opportunity of marking its limits, it should neither, on the one hand, be too great, when the sides and bottom, exposed to the rapidity of the current, are apt to be injured, and to require frequent and expensive repairs, nor, on the other hand, should the inclination of the drain be too small, by which the current becomes sluggish and stagnant, and the land is not fully relieved from water.

No precise rules can be laid down for the dimensions of open drains, as they must be varied according to the nature of the soil, the situation, and the quantity of water to be carried off. The width at the bottom of the drain must be regulated by the proportion of water to be discharged; and it may be stated as a general rule, that the width at top should be at least three times greater than the bottom, to admit of sufficient slope and solidity to the sides. But in soft and mossy soils a greater slope is requisite; and when the drain is not proposed to be a fence as well as a sewer for conveying the water, the earthy matters thrown out should not be left on the sides to form an elevated bank, but spread on the field, or removed. In soft marshy grounds, where the drain is also required to be a fence, the bank of earth, which should always be thrown out on the lower side, may be allowed to remain, and a small parallel cut may be opened to receive the surface-water from that side, and to conduct it to a convenient place, where it may be admitted into the larger drain.

Wherever there is much risk of surface-water being greatly increased in the time of rain or floods, open drains must always be preferred, to avoid the danger of being entirely obstructed, to which covered drains are liable. But as such drains, constructed in the usual way, would disfigure an improved field, and interrupt tillage operations, they ought to have a greater slope, and a green sward should be permitted to form on their sides. If the direction of the ridges be parallel to the drain, the cultivation of the field is uninterrupted; and when it is in pasture, it presents no obstacle to the free passage of cattle. But it ought to be observed, that whatever be the slope of such drains, the sides should never be ploughed; for any increased flow of water would carry off the loosened soil.

Surface-water is removed from lawns and smooth sheep pastures by means of a simple operation with a strong common plough. Let a deep furrow be turned up through the hollow parts of the field where water stagnates, pare off the earth from the inverted sod, leaving it about three inches thick, and return it to its natural position. In this way a small hollow drain of three or four inches is left in the bottom of the furrow, which is found sufficient to discharge a considerable quantity of water. By this easy process, a great extent of drain can be executed in a short time; and when any part is obstructed, it can be repaired at a small expense. The earth which is pared off may be removed to hollow parts of the field, or spread on the ground.

Lands which are appropriated to woods or plantations of any kind, derive no less benefit from draining than what is destined to corn or herbage crops. For this purpose, open or surface drains are the most suitable: for, in covered drains, the roots of the trees and underwood, stretching along horizontally, insinuate themselves among the stones, and thus interrupt, and at last entirely obstruct, the passage of the water.

Draining stiff, flat Soils.—In many cases, where the surface is flat, and the soil of a stiff and retentive nature, attempts to dry the ground by means of covered drains are found to be ineffectual. In most of the central counties of England, and in the flat land of Flanders, the land is relieved from surface-water by forming high and broad ridges of twenty, thirty, and even forty feet wide, and having the crown three and sometimes four feet higher than the bottom of the furrows. The beneficial effects of this method of draining are fully confirmed by the successful practice of the Flemings; for when furrows are kept free from water, the land is always dry, and the crop healthy and abundant. But in some parts of England, from the improper direction and flatness of the ridges, and the shallowness of the furrows, these good effects have not been obtained; for the water, stagnated in all the hollow places, renders those parts of the field useless, has even brought some degree of discredit on the method itself, and has led to the adoption of other less perfect methods of draining. The indiscriminate formation of high ridges has been justly censured. On a dry, loamy soil, they are altogether unnecessary; but when they are well rounded, not too much elevated, and the furrows kept clear, they afford the best and most efficacious method of rendering land of a retentive surface perfectly dry.

In some cases, from the peculiar nature of the soil, the practice of combining open and hollow drains has been found extremely beneficial. The following is the method adopted by Mr Goade of Cossington, in Leicestershire. The soil on which he operated is sandy on the surface, from six to ten inches deep, red clay at the bottom, and in some places gravel, from which the water is thrown upon the surface of the land. Finding it difficult to drain the soil, he formed hollow drains in the furrows. The ridges are from five to ten yards broad, aud varying in height, being raised, for summer corn, only six inches, but for winter crops twelve inches at the crown, above the bottom of the furrows. In turf ground, the hollow drains are dug fifteen inches wide, and two feet deep, sloping downwards. The turf is first cut out, and with another implement, which is seven inches wide at the top, and becoming narrower to the length of sixteen inches, the other materials, whether sand, gravel, or clay, are thrown out. When the bottom of the drain is of clay, it is cut four inches deeper in the middle, and only four inches wide, leaving two inches on each side, or what are called *shoulders*, to support the turf, which is laid flat upon it, with the grass side downwards. The upper part of the cavity is then filled up. When the land is of a mixed soil, thorns, or elder boughs, are laid, and trodden down in the drain; after which the turf is laid upon them as before, and close to the sides of the drain: but where slate, or thin slabs of stone can be obtained, the construction is more solid, and the operation more complete. In clearing out the bottom of the drain, which is about four inches wide, an instrument somewhat resembling a hoe, of the form of the letter L, and half rounded at the lower end, is employed. Drains of this description have operated for fifteen years without interruption, and even when filled with bushes; it is expected that they will continue uninjured for a much longer period; and it is added, that the improvement ought not to be estimated at less than one-fourth increase of the crop.

The method of relieving a retentive soil from water, by means of surface-draining, as it is practised in the Carse of Gowrie, in Perthshire in Scotland, and described by Mr Paterson of Castle-Huntly, is also worthy of notice. This simple operation is the only means which is employed in draining that extensive flat. Large common drains, traversing the district in different directions, and of sufficient capacity to receive the water conducted from the fields by the surrounding ditches, discharge their collected waters into the river Tay. Every farm is surrounded or traversed by ditches, as may suit the particular situation, all of which are so directed and arranged as to form a communication with every field on the possession. The breadth of these ditches is from two to four feet at top, and from a foot to a foot and half at bottom, and with such a slope as to prevent their sides from falling in. If the fields be of an uniform level surface, the common furrows between the ridges, with sufficient depth at their extremities, serve to carry off the redundant water; but in a field of unequal surface, the last operation, after the sowing and harrowing are completed, is to draw a furrow with the plough through all the hollows which lie in such a direction that it can be guided through them, and thus form a free communication with any of the furrows between the ridges, which latter are conductors of the water to the surrounding ditches. When this furrow is formed by the plough, it is widened, cleared out, and dressed with the spade, that the risk of filling up may be avoided. The width is from six inches to a foot, according to the depth; but the breadth of a spade at bottom is generally found sufficient. It often happens that inequalities, or hollows, do not extend across the field, or pass through it in any direction to be followed by a plough, but are limited to one or two ridges. In such cases, the furrow is to be made by the spade, and the communication formed with the nearest furrow in the vicinity.

In the Carse of Gowrie, it is yet the general practice to have head ridges at the extremities of each field. These transverse ridges, on which the plough turns, are higher in the middle, and fall off at each side; and the inner furrow, communicating with all the furrows of the longitudinal ridges, receives all

Draining.

their surface-water, and discharges it by an open drain, cut through the head or transverse ridge, into the adjoining ditches. But the same writer observes, that the surface-water passes off more freely, and the drain is more perfect, when no transverse or head ridge is formed; and this method Mr Paterson has successfully followed on all the fields which he has levelled. To avoid these head ridges, he lays up the earth uniformly to the ends of the longitudinal ridges; and this, although with a little more trouble, is easily effected, by returning with an empty plough. In this way, there is no depression between the longitudinal and tranverse ridges, but the longitudinal furrow is carried fairly through the head ridge. Besides this management, it is found by ample experience, in this rich district, that by careful ploughing, laying up the land equally, and rounding the ridges properly, so that they are neither too high nor too low, all the surface-water is easily removed; and while the crowns are neither too much enriched, nor the furrows impoverished, the whole becomes equally dry and fertile, and is frequently earlier accessible to the plough in the spring than more elevated grounds in the vicinity.

Sect. II. *Of Under-ground Draining.*

The wetness of land, it has been already remarked, arises, either from rainwater collecting in hollow places on the surface, or from the water of springs, forced up from below; and it is easy to discover from which of these causes the moisture proceeds, by the nature of the plants which are produced on the wet soil. When the land is kept in a soft and spongy state by surface-water, that species of rush known by the name of *spret*, *(juncus articulatus, Linn.)* grows up in abundance; but the common rush *(juncus conglomeratus, Linn.)* appearing in hollows or the sides of declivities, affords a sure indication of the soil being drenched with water rising from below. The method of drying the soil in the latter case, which is one of the most essential improvements of which modern agriculture can boast, depends on an accurate knowledge of the distribution of the strata, and of the circulation of water in the bowels of the earth, or of the nature and origin of springs.

Origin of springs.—The water which falls from the clouds, in the form of rain or snow, to the earth, partly returns to the atmosphere by the process of evaporation; partly flows from the higher to the lower grounds, to form rivers; and partly sinks into the soil, and passes through various kinds of strata, to give origin to springs. If, in going downwards, a bed of gravel or sand succeed to a loamy or sandy-surface soil, and repose on a stratum of clay, the rain-water immediately filtrates through the open soil, and accumulates in the sand or gravel; for its passage is interrupted by the bed of clay. If one extremity of this bed of gravel or sand be more elevated than the other, a pit, dug in the lower extremity, is soon filled with water; and, according to the difference of elevation, may rise to the surface, or overflow. When the extent of surface from which a bed of gravel, or any other porous stratum, is supplied with rain-water, is considerable, the springs are perennial; when of smaller extent, the flow of water ceases during the dry season; and, when still more limited, the springs yield water only in the time of heavy rains.

Draining.

The materials of which the earth is composed, as far as human research has extended, are very different with regard to the property of retaining water, or of allowing it to pass freely through them. Great diversity, in this respect, prevails in the soil, or immediate covering of the earth, in which vegetables grow; and hence soils are characterised as wet and dry according as they are more or less retentive or porous. A stiff, clay soil, which allows no water to pass through it, and a sandy soil which retains none, may be regarded as the extremes in the description of wet and dry soils. A similar diversity is observed in the under stratum or subsoil, as it happens to be clay, gravel, or sand, as well as in the strata of solid rocks. Beds of clay, or of gravel and clay, argillaceous rocks in general, and rocks in which there are few fissures or openings, retard, or entirely interrupt the progress of water through them. But strata of gravel and sand, sandstone, basaltic or whinstone rocks, calcareous rocks, as chalk beds, different varieties of limestone and marl, from their absorbent or porous nature, or from the fissures or caverns which abound in some of them, readily receive water, and often as freely allow it to escape. The whole art of draining, according to the new method, depends on a precise knowledge of these materials, whether they refer to the soil and subsoil, the alluvial strata, or the solid rocks, and of their mode of distribution and relative position.

The first thing to be considered in draining land is the source of the wetness; whether it be surface-water, which, from some obstruction, is not permitted to pass off freely, or water thrown up from some of the inferior strata. If a hollow piece of ground be covered with water, or if it should be only wet and spongy during great part of the year, and even during the dry season; and when this ground has been for some time retained in pasture, if the common rush begin to shoot up and thrive on the edges of the wet spot, where the soil is somewhat more solid, and if it stretch upwards on the sides of the declivity, or more particularly to a greater height on one side,—then the conclusion is pretty certain that the water proceeds from the underground strata, from a bed of gravel, or other porous matter, at some depth under the surface, and supported by an impervious stratum, as a bed of clay. But the certainty of this conclusion can be easily put to the test by a simple experiment. If a pit be dug at the upper edge of the space occupied by the rushes, to the depth of two or three feet, which must vary according to the thickness of the different strata and the depth of the porous bed through which the water filtrates as soon as the latter stratum is penetrated, the water rises in the pit, and perhaps in a short time overflows and runs along the surface. But if a cut, of sufficient dimensions to convey the whole of the water to the nearest ditch, be made, it is probable the wet ground will be relieved from the water, the rushes will disappear, and plants of a very different character take their place. In case no water should appear in the pit, after digging to a mederate depth, or if it should not be convenient to penetrate deeper than one foot and a half or two feet, recourse may be had to the borer or auger, an instrument employed for this purpose, to form a communication with the porous stratum containing the water, to the depth of many feet or fathoms. When the borer reaches the porous stratum, and is withdrawn, those who witness this interesting and beautiful experiment, will be gratified with seeing the water burst up with considerable force, and soon fill the pit; and if the communication thus formed continue uninterrupted, the ground becomes dry, and is rendered fit for all the purposes of tillage. The cause of the wetness at the place where it appears is easily explained: The water accumulates in the porous stratum, increases the pressure on all sides, and having burst the upper covering, forces a passage for itself, and oozes through the soil along the declivity, and, when the spring is copious, collects in the hollow ground, and forms a marsh. This operation, however simple and obvious it may appear, now that it is well known and distinctly understood, must always be regarded as one of the most beneficial agricultural improvements, because it is the foundation of every other; and if it must be less ascribed to accident than to observation and reasoning, the merit of the successful discoverer has not yet been sufficiently appreciated.

Discovery of tapping springs.—Two competitors have appeared, claiming the merit of this valuable discovery; and, after all that has been said and written on the controversy, it is difficult to say to whom the claim of priority ought to be allowed. Dr James Anderson, so well known for his numerous writings on rural affairs, published essays in 1775, in which he gives a full and clear statement of the nature and effects of the operations which he practised on his own property in Aberdeenshire in the year 1764. The first published account of Mr Elkington's claim to the merit of the discovery, appeared in an excellent work on draining, by Mr Johnstone, surveyor, who, in 1796, had visited Mr Elkington, and accompanied him in an extensive tour through different parts of England to see and examine the effects of his new system. According to the account of the origin and progress of his operations, given in the work just alluded to, Mr Elkington was left by his father in possession of the farm of Princethorpe, in Warwickshire, in the year 1763. The poverty and wetness of the soil occasioned the rot among his sheep, and several hundreds perished. This severe loss naturally led him to attempt to obviate the cause, by draining his grounds; and in the succeeding year (1764) he commenced his first operation on a clay-soil, approaching nearly to the state of a swamp or shaking-bog, in consequence of the water discharged from the springs of the contiguous bank of gravel and sand, and overflowing the low ground. For the purpose of draining this field, he cut a trench, four or five feet deep, a little below the upper side of the bog, where the wetness first appeared. Proceeding in the same direction, and at the same depth, he was disappointed in his expectation of reaching the reservoir from which he suspected the water arose. A servant came to the field at this time with an iron crow or bar for another purpose. Mr Elkington, thinking the trench too shallow, or wishing to examine the nature of the strata below, took the iron bar, forced it to the depth of four feet below the bottom of the drain, and was not a little astonished to see a great quantity of water burst up through the opening, and run along in a copious current. Thus, it is said, chance was the parent of a discovery, which led Mr Elkington to the knowledge, that wetness of the soil is often produced by water proceeding from a greater depth than any drain can reach; and also led him to the use of the auger, a most valuable instrument in the operation of draining. Mr Elkington not only succeeded in relieving his own farm from water, and producing sound pasture, but became a professed drainer; and, after the lapse of more than thirty years, had the good fortune to receive a reward of L.1000 Sterling from the British parliament for his discovery.

Principles of the new system.—The principles of draining, according to this mode, are few, and extremely simple. Three circumstances require to be attended to: 1st, The discovery of the main spring; 2d, The determination of the course and inclination of the strata; and, 3d, The use of the auger, in cases where the spring is beyond the reach of the ordinary depth of a drain.

In proceeding, according to this method of draining, the neighbouring high grounds are to be examined, to ascertain precisely the nature, composition, and inclination of the strata, and their relative position with the ground to be drained; from which an opinion can be formed of the nearest point where the water may be cut off and discharged by the level of the spring. To obtain this necessary information, the beds of the nearest streams, the face of steep banks, pits, wells, and quarries, are to be minutely surveyed. Having discovered the main spring, the next object is to determine accurately the line of level in which the drain is to be conducted. This is one of the most important parts of the operation, and requires particular attention. The last part of the operation is the application of the auger, which is employed in all cases where the outlet, or the expense, or difficulty of execution, does not admit the drain to be cut so deep as to reach the spring.

Spring bogs.—The application of the principles now laid down, will not, we apprehend, be difficult, when all the circumstances are fully considered. Suppose there is an extensive flat of swampy land, lying on the bank of a river, and from the examination of the appearances, it is concluded that the supply of water is derived from numerous springs, indications of which are distinctly observed on the declivity of the adjoining elevated bank, which forms the boundary of the bog on one side; and suppose, first, that all the springs arise along the upper edge of the wet ground,—then it will be found, that a single drain, conducted in the direction of these springs, will effectually carry off the redundant water. But let it be supposed farther, that on examining the surface from which the springs issue, they appear at different levels, that the upper series of springs is exhausted in the dry season, while those in the lower part of the declivity continue to flow, the conclusion in this

Draining. case is pretty certain, that the whole springs are derived from the same source. The lowest are to be considered as the main springs, and the line of the drain is to be conducted in their direction, by which the supply of water is completely intercepted. If the drain were carried in the direction of the upper line of springs, it would also answer the purpose, but it would require deeper cutting, and therefore a greater expence would be incurred; or the use of the auger might be required, which is superseded by the first method in such cases. It is scarcely necessary to add, that extensive bogs or swamps may require subsidiary trenches in different places, to carry off the whole of the water.

Drainage of hills.—The irregular distribution of the strata of which hills are composed, frequently produces alternate portions of wet and dry ground on the surface. The general aspect of the ground, the nature of the plants, and the degree of wetness which prevails, may often indicate the kind and arrangement of the strata, as well as the proper direction of the drain. When the rock is horizontal, or is only slightly inclined, all the springs may derive their waters from the same source, and this being exhausted, the object is attained. But in cases where the rock is nearly in a vertical position, and contains partial collections of water in fissures and cavities, it is necessary to carry a drain to each outlet.

When hills are composed of alternate strata of rock, sand, and clay, the surface of the clay is sometimes soft and spongy, while the soil incumbent on the rock and sand is sufficiently dry to produce good herbage. Here a drain is required for every division of wet and dry soil. Figures 1. and 2. Plate 2. will serve to illustrate the method of draining in such a case. Fig. 1. a plan of the ground, in which AAA represents the dry porous soil; BB, BB, BB, the wet soil. A drain C is cut under the upper line of springs *aa*; a second drain C along the next lower line *aa*; and a third C is cut along the lowest *aa*; and a communication being formed between each of these drains, the whole collected waters are conducted to the nearest outlet. Fig. 2. is a section of the same hill; AAA the dry and porous strata; BBB the clay or impervious strata, on the surface of which the wetness appears; C the upper line of springs, with the drain or cut immediately below it; D the second line, with their drain; E the third line, with their drain; and F the lowest drain, by which the whole water is discharged. We have not mentioned the boring operation in this case; but it may be equally efficient when particular circumstances require it.

Drainage of land-locked bogs.—A most important and beautiful application of the same principles has been made in the draining of bogs, or morasses, which are surrounded on all sides by high impervious banks. Fig 3. Plate 2. represents a bog, or morass, of this description. ABCD is the high bank of clay, or other impervious substance; EFG the wet or boggy ground; HIKL the points where the transverse drains meet the longitudinal drain. Fig. 4. is a section of the same bog, and of the contiguous strata. AB the high impervious bank, connected at NOP, and containing the water as in a bason; CD a porous stratum below, under which EF is a stratum of impervious clay; GHIK are the drains, at the bottom of which the auger is inserted. Draining.

In carrying off a collection of water in such circumstances, the first step is to form a drain in the middle or lowest part of the boggy ground; and to this drain all the others, the number and direction of which regulated by the extent of surface to be drained, are conducted. When the drains have been carried to the impervious stratum of clay, the use of the auger is had recourse to, to perforate the stratum, and to allow the water to escape to the porous stratum below, from the lower part of which it may be discharged by some convenient outlet. It is not necessary that the drains in such cases as the present should be wide; they may be cut as narrow as can be conveniently executed; they should be filled up with small stones to within a foot and a half of the top, that the water may be permitted to ooze freely through the peaty soil and escape downwards; and they should be covered, that no earthy matters may be washed into the auger holes and choke them up. A bog of this description has been successfully drained in this way in Dumfries-shire, on Mount Annan, belonging to General Dirom. In the counties of Peebles and Roxburgh, in Scotland, similar attempts have been made with equal success.

Sect. III. *Of the Construction of Drains.*

In planning and executing drains, various objects must come under consideration; as, the dimensions,—the implements to be employed,—the materials for filling them,—the expence,—and the season in which the work should be done. On the first point little need be said. The dimensions should be such as to allow the water to pass off freely, and the sides should have a greater or less degree of slope, according to the nature of the soil and strata through which the drain is carried.

Implements.—In many cases the usual implements, as the spade, shovel, and mattock, are all that are required. But in cutting narrow drains to a considerable depth, a spade whose lower extremity is considerably narrower, and another which terminates in a point, are very useful instruments. A scoop, which forms nearly a right angle with the handle to which it is attached, is a necessary implement for clearing out earth or gravel from the bottom of drains. The auger, or wimble, employed in draining, resembles the wimble of the carpenters; the diameter is 3 inches, the length of the hollow part is 18 inches, and the opening at the sides is only 1 inch. The rods to which the auger is screwed are $1\frac{1}{4}$ inches square, and 4 feet long, and they are also screwed to each other. The construction and management of the boring apparatus are exactly similar to that employed in searching for coal. A chissel $2\frac{1}{2}$ inches broad at the point, and well sharpened, is necessary for cutting through stone; a punch $1\frac{1}{2}$ inch square, also with a sharp point, is requisite for perforating gravel; and a kind of scoop should be made for cleaning the auger.

The operation of boring is conducted exactly in the same way as in boring for coal; and the only precaution to be recommended is, that the perforation should never be carried deeper than the length of the auger without withdrawing and cleaning it; for the earth and gravel are apt to fill up the vacant space above and render it extremely difficult to pull it up.

Materials for constructing hollow drains.—The selection of the materials for constructing or filling drains is not always left to choice; and as the quantity required is often very considerable, such as are most abundant are preferred to what are of a more durable nature, from motives of economy. Very different materials have been employed for this purpose, as bricks, stones, wood, brush-wood, straw, &c. But the various methods which have been adopted may be readily understood by a short reference to the figures.

Fig. 5. represents a drain of $2\frac{1}{2}$ feet wide at top, and 18 inches at the bottom, cut through one foot of porous upper soil at A, one foot of sand and gravel at C, and six inches of clay at D. The passage for the water at D, of six inches square, is formed by a line of stone, and is covered with a flat stone, four inches thick. A layer of rounded land stones, one foot thick, replaces the sand and gravel at C. An inverted sod, two inches thick, covers the stones, and the space above is filled with loose mould.

Fig. 6. is a drain nearly of the same dimensions, and cut through similar strata. The opening for the passage of the water is triangular, and six or eight inches wide; it is covered with a flat stone, four inches thick at D. The space at C is filled with rounded land stones, or faggots of brushwood; the covering at B is an inverted sod, straw, heath, or rushes, and the loose mould at A fills it to the top.

Fig. 7. is also of the same dimensions, and is filled with the same materials; the opening of six or eight inches being triangular, or coupled, is formed by two flat stones, placed on the stratum of clay, and brought into contact at the top.

Fig. 8. is a drain of $2\frac{1}{2}$ feet wide at top, and one foot at bottom, cut entirely through clay soil. It is filled up with a stratum of land stones of 20 inches in thickness at C, which is covered with four inches of sod, straw, heath, or rushes; and the remaining foot to the surface is filled up with loose mould or gravel.

Fig. 9. is a drain of the same dimensions as the last, in which brushwood is placed lengthways, and supported by cross billets of wood, leaving a triangular passage at the bottom, and the sides open to the height of the cross billets, which is 18 inches at C. The brushwood is covered with a layer of strong heath or rushes at B, and the loose mould is thrown in to the top.

Fig. 10. is a drain cut into clay soil, having a triangular opening C, of one foot deep, and eight inches wide at the shoulders, formed by the pointed draining spade. It is covered with six inches of inverted sod B, and the upper part is filled with gravel or loose mould.

Fig. 11. is a drain formed in 1 foot of gravel or porous soil, and a triangular opening C is formed a foot deep in clay. The opening is filled with three large straw ropes, placed length ways. A layer of six inches of clay is trodden down, and the drain is filled with gravel to the surface.

A simple and ingenious method of constructing a pipe drain has been practised, by digging it to the depth required, and making it very narrow at bottom. A smooth cylindrical piece of wood is prepared, of ten or twelve feet in length, of six inches diameter at one extremity, and five inches at the other. A little sand is scattered in the bottom of the trench; the tree is then laid in; and, after a little more sand has been thrown on its upper side, the clay, or most adhesive part of the materials, is first replaced; the trench is then filled; and the whole is firmly trodden down. By means of a ring or rope attached to the tree, it is drawn out, leaving only a foot or two of the smaller extremity covered, and the repetition of the operation is continued till the work be completed. This clay pipe, which in one case has remained in good repair for above twenty years, is supposed to answer better for the conveyance of water than for drying the soil.

The best season for executing work of this description is summer or autumn, when the surface of the soil is most free from moisture. The expense of draining, it is obvious, must vary according to the price of labour in different districts, and the abundance or scarcity of the requisite materials. But it has been stated, that the expense of draining in few situations has exceeded L.10 per acre; in many it is much less; and this must always render it an object of economical management.

Sect. IV. *Of Embankments.*

A great deal of valuable land has been protected or reclaimed from inundations of rivers, the sea, or lakes, by judicious embankments. In this way extensive tracts of the very best kind of land have been gained, and in many cases at a very trifling expense. The ingenuity and industry of the Dutch, in executing works of this kind, are well known. A large proportion of the flat country of Holland has been gained in this manner; and in England, Scotland, and Ireland, a great extent of the richest soil has been brought to a cultivated and productive state. Embankments for protecting or reclaiming land are employed against rivers, lakes, and the sea.

Embanking of rivers.—The embankments against rivers are intended to prevent their encroachment on the lands contiguous to their banks, or for protecting the adjoining flat country from being overflowed in the time of floods. A river running nearly in a straight line, rarely encroaches upon its banks, unless when it is large, and rises above its ordinary level, by an increase of its water, or by an influx of the tides of the ocean. When any injury is threatened to the bank from these causes, it may be secured with stones, or by driving a row of long piles pretty close together, at a small distance from the shore. The piles must be of such a length, that their tops shall be always above the highest rise of the water. Very remarkable effects have been produced by such a construction in resisting the force of the waves; and an example of a successful operation of this kind, executed by Mr Beatson, to defend the walls of a fort near Portsmouth from the waves of the sea, has been often particularly mentioned. The same simple method is recommended to protect the

Draining.

banks of large rivers which are exposed to the violence of the waves.

But the most common injury to which the banks of rivers are subjected, arises from abrupt turns in their course, in consequence of which the whole force of the stream is directed against a small space. In rivers which flow through flat countries, and are of no great magnitude, the most effectual method of proceeding to prevent the injury would be to straighten their course. But when the size of the stream, and the particular situation, render this plan impracticable, the force of the water is either to be diverted to another point where it can produce no injury, or is to be divided, or as it were spread over a larger surface. The force of the current may be directed to another point, by forming some obstruction at a short distance above the place where the obstruction has commenced. This is usually done by means of a wall of stone carried out from the bank towards the middle of the current, and pointing down the stream in such a way that it shall form with it a pretty obtuse angle. But it would be a more effectual method, where it is practicable, to enlarge the turn or bend of the river; by which the force of the water, acting on a wider surface, is greatly diminished at particular points.

Rivers are embanked to prevent them overflowing and inundating large tracts of flat country. Inundations of this kind may sometimes be obviated, by giving the current as much space as possible, by widening the bed of the river at narrow places, and by removing every kind of obstruction, as shoals, stones, trees, or bushes. But where embanking is unavoidable, the banks should be erected at such a distance from each other as shall allow sufficient space to contain the whole water in the time of the greatest floods. It rarely happens that rivers which flow with a free and uninterrupted current, even during the greatest floods, rise higher than five or six feet above their ordinary level. An embankment, therefore, of six or seven feet in height, will, in general, be a complete security against inundation. The base of an embankment should be three times the breadth of its height, and the width at top should be at least one third of the height, and the slope should always be greatest towards the stream, by which the force of the water is diminished. If an embankment be six feet high, the base should be eighteen feet, and the top is diminished to two feet. The line of an embankment should be at a proper distance from the edge of the river; and the whole materials of which it is formed should be taken from the land side, that the surface next the river may not be loosened and exposed to its encroachments. All trees and bushes should be removed from the space between the embankment and the river, that no interruption may be opposed to its current; and none should be allowed to remain in the line of the embankment.

In the construction of an embankment, the materials of which it is composed should be made as solid and compact as possible, by being trodden or beaten down with heavy mallets; and when there are any substances of a tough nature, as clay, they should be employed on that side next the river. When the slope is finished, the same side is carefully covered with well swarded turf, the first layers of which, next the foundation, it may be necessary to pin down; and in dry seasons it may be proper to water them, to make them adhere more firmly together. The land side of the embankment is sown with grass seeds; and it may be useful in thickening the sward to do the same on the other side. Embankments of rivers should commence at the upper part, and be carried downwards; and each day's work should, if possible, be entirely completed, to prevent the injury from sudden swells of the river; and, that the embankment may be uniform and regular through its whole course, a wooden frame, of the exact form and dimensions, is constructed for the direction of the workmen. A back drain, at the distance of two or three feet from the inner edge of the bank, is necessary to receive the surface water; and the whole water collected in the adjoining fields should be discharged by one outlet only, at the lowest part of the embankment, by means of a pipe or square wooden box, having a valve or lid attached to the mouth, by hinges on the upper side. This valve, shutting in the time of floods, excludes the water of the river; and opening by the pressure of the water from the land, allows it to escape when the river subsides. No trees or shrubs that penetrate deep with their roots, or grow to any considerable height, should be planted on the sides or top of an embankment; for they loosen the earth, and shake the whole mass: but rushes, flags, colt's-foot, and some other plants, may be sown and encouraged to grow, because their roots, stretching along the surface, and forming a kind of close mat, increase the solidity of the construction. Embankments, even when they are finished in the best and most careful manner, should be frequently examined, that the slightest breach which appears should be instantly repaired; and mice or mole holes, which give free admission to the water, and may be the commencement of the most serious injury, should be immediately shut up.

Embankment of lakes.—The waters of many lakes cover a much greater extent of surface in winter than in summer. It would therefore be an important object, and some valuable land might thus be acquired, to confine them within the narrowest limits. In some cases, this may be effected by widening and deepening the principal outlet; but if the level of the ground should not admit of this method being pursued, or if an intervening mass of rock should render the operation too expensive, the water may be confined by an embankment. The summer season, when the water is lowest, is undoubtedly the best time for attempting an operation of this kind; and the dimensions of the embankment, and the necessary precautions in proceeding in the work, completing and securing it, are similar to those already stated. A back-drain, to carry off the surface-water, is also required in this case; and when the lake is surrounded by elevated ground, it may be proper to conduct another drain along the line of springs which burst out from the adjoining bank.

Embankment of the sea.—The sea increases on the land, either by destroying and washing away the materials, when they are of a loose and soft nature, or by overflowing flat grounds during high tides. When perpendicular cliffs of clay, or other alluvial soil, mixed with loose stones, are opposed to the force of a stormy ocean, its ravages are almost irresistible. The usual mode of defending the land, in such cases, is by constructing a bulwark of stone in front of the bank. To give complete security to such bulwarks, the base should be broader, and the slope greater, than they are usually made, while the top of the building should be so elevated as to be above the reach of every tide. Piles driven into the shore, in front of the bulwark, have been found a very effectual expedient in breaking the force of the waves; but one of the most important precautions, in bulwarks of this kind, is, to secure the whole line of coast which is exposed to the action of the waves; for if the water be admitted at any one point behind the embankment, it produces a double injury, not only by its pressure on the stones while it recedes, but by washing out the earth from behind them, and loosening their foundation.

When it is difficult, or very expensive, to procure proper materials for such works, and when the force of the water is not very great, an embankment may be constructed of small stones, coarse gravel, or broken bricks. By spreading them about a foot thick on the surface, and beating them well down, a safe and durable fence is formed. But embankments of this description must have a greater degree of slope.

Some of the richest, and most fertile land in the kingdom, has been reclaimed from the sea by means of embankments. Such land is generally situated at the mouths of rivers, or on the shores of bays, or arms of the sea. The facility of reclaiming land which is covered every tide, in bays, creeks, or on the side of a large river, must depend on the depth of the water, the rapidity of the current, and the prevailing winds, and its expence and success on the nature of the soil, or materials of which the beach is composed. If the materials be of a sandy consistence, the embankment must be faced with stones on the side next the sea; but where the materials of the bank are of clay, or some adhesive matter, strong turf may be employed; but it must be well beaten, and secured with pegs. The height and solidity of embankments of this kind are determined by the rise and force of the water. In the inside of sea embankments, drains are to be cut to carry off the surface water, and sluices are to be constructed, to allow it to escape during the ebb-tide. In some cases the course of a stream has been advantageously changed, to allow it to discharge its waters where it is less liable to injure the soil; and in one case the course of a river was reversed, by conducting it in an opposite direction.

Chap. II. Of Inclosing Land.

The whole of a farm is rarely or never under the same species of crop at the same time. One part is under arable culture, and is appropriated to the production of corn, and another is in the state of pasture land: and while the latter is consumed by live-stock, the former must be protected from their ravages. Hence inclosures and fences become an object of great importance in all well managed lands, and contribute essentially to the successful prosecution of every regulated system of husbandry. In the present chapter, which is devoted to that subject, we shall treat first of inclosures, and secondly of fences.

Sect. I. *Of Inclosures.*

Number of inclosures.—The situation and extent of a farm, the nature of the soil, and the kind of husbandry to be adopted, must in a great measure direct the number and extent of the divisions or inclosures into which it ought to be formed. If the same species of crops, and a similar system of rotation, are pursued on two farms, one of which is double the extent of the other, the number of divisions for the conveniency of management must be the same; but the size of each division on the farm of smaller extent can only be one half.

In the general division of arable and pasture lands on any possession, it is always found convenient to have a few inclosures in the state of grass, near the house or farm offices. Such inclosures may be considered as exclusive of the more general distribution of the farm into arable and pasture lands; for while such portions of it as are usually cut for hay, or are employed as pasture for store cattle and sheep, may be, without inconvenience, laid out at a distance, those which are usually under arable crops should be near at hand, that time and labour may not be lost in the travelling of the teams and the cartage of the various kinds of produce.

The quality of the lands must have considerable influence in regulating the size and number of inclosures. In farms which have a sufficient extent of land of opposite qualities, as those that are porous and absorbent, and such as are retentive of moisture, it may be a convenient and judicious plan to have two sets of inclosures, by which means the whole operations connected with arable culture may suffer less interruption from the extremes of wet and dry weather, and the live stock may have an ample provision of pasturage during all seasons. If, for instance, in the system of rotation, a six years course be adopted, the division of the farm into twelve inclosures will be found extremely commodious. By this arrangement, two inclosures of different kinds of soil, of different degrees of fertility, and in different parts of the possession, may be under the same crop, and thus equal distribution of labour, and equal returns of produce, which are no inconsiderable advantages, are attained. In cases where the turnip husbandry forms part of the rotation, two inclosures in different situations, the one in a distant part of the farm, and the other near the offices, afford the means of obviating the great expense and trouble of conveying the produce from any unnecessary distance. The fields of turnips near the house may be reserved for consumption in the straw yard, while the more distant crop may be conveniently eaten on the ground. The diversity of soil which often prevails in the same field, when it is of large extent, frequently occasions considerable variation in the quantity of labour required in working it, as well as in the amount of produce which it yields. One part of a field of this description may have a poor soil, and require great labour

Inclosing.

and exertion in its preparation, while another part is of a richer quality, and is wrought with greater facility. One part of a large field may be of such a nature, or so favourably situated, as to admit of all kinds of operations during a great part of the season, while another part can only be attempted in the most favourable periods. But when such fields are divided into one or more inclosures, one which is of a poor soil may be combined with another of a richer soil; one which is easily cultivated may be joined with another which requires much labour; and thus the quantity of labour, and the amount of produce, may approach nearly to the same point during all ordinary seasons.

In the distribution of pasture land, it has been recommended to have two or more inclosures, in preference to the same extent in a large field. By this subdivision, the stock may be separated into small parcels, and that portion of it which is first intended for the market may be introduced to the earliest and best pasture. In the most celebrated grazing counties of England, inclosures of a moderate size are found to be highly advantageous: but at the same time it is recommended that sheep pastures should be of large extent; for as this species of stock is more restless, and more easily disturbed than any other, and as they are apt to be impatient of heat, and often greatly annoyed by insects, when they are confined in small sized inclosures, surrounded by high hedges and trees, they ought to have a wider range in larger fields.

Form, &c.—The shape or form of inclosures is, in some measure, regulated by the form of the farm, the nature, surface, and aspect of the grounds, and the direction of the roads and water-courses by which it is traversed; but, in general, when it can be managed, inclosures in the form of a square, or long square, should be preferred, and all crooked and irregular shapes should be avoided. The two sides of the inclosure should lie parallel to each other, for the conveniency of arranging the ridges; but it is equally, if not more necessary, that attention should be paid to the uniformity of soil in the same field.

The direction of inclosures, when it is compatible with the form of the farm and other circumstances, should be the same as that in which the operation of ploughing can be most conveniently accomplished. The direction of an inclosure, on a level surface, or one with a gentle inclination, where the retentive soil requires to be laid up in rounded ridges, should be nearly north and south; because, by such an exposure, the crop on the different sides enjoys more equally the influence of the sun, and comes more regularly to maturity. But in situations where the surface is steep, and the soil also retentive, the direction of the inclosure is regulated by the nature or face of the slope, winding to the right, when standing on the brink of it, for the purpose of arranging the ridges in the same direction, and of more easy ploughing them. But when the soil is of an absorbent or porous nature, and the slope very steep, the direction of the inclosure should be turned downwards of the declivity.

In laying out watered meadows, where the situation admits of such, attention must be paid to the nature of the ground, that a full command of water may be at all times within reach. And, in inclosures destined for pasture or grazing lands, it is scarcely necessary to add, that an abundant supply of water is of essential benefit to the stock; so that, in the subdivision of the grounds, the means of obtaining it should be always kept in view. In the subdivision of land, some advantage may be obtained, by combining the means to be adopted in draining, with the arrangement of the inclosures; and this advantage ought not to be overlooked.

Advantages.—Inclosures are not only useful, in ascertaining and securing property, but they afford the utmost facility to improvement in all systems of management. In consequence of the shelter which is thus obtained, the quantity and value of the produce are increased. When under arable culture, and when in the state of pasture, the greater number and superior value of the live stock reared on an equal extent of ground, are universally admitted. Inclosing is stated as the first step towards effecting improvements in the breeds of the different species of live stock; but the additional rent, which is obtained for inclosed land of equal extent and quality with that which is in the state of open field, affords the most satisfactory proof of its advantages.

Sect. II. *Of Fences.*

Fences are not only useful in affording shelter to inclosures, but are necessary for confining live stock, and protecting arable crops from their depredations. Fences have been divided into two kinds, *simple* and *compound*. Ditches, hedges, palings, walls, &c. belong to the first kind; and under the second, are included such as require the assistance of another kind of fence, either to protect or render them secure, as hedge and ditches, or banks, hedge and wall, &c.

Ditch-fence.—In some cases, ditches are not only employed for the purpose of carrying off water, but also for that of a fence to the inclosure. With this view, it is necessary that they should be deep and wide; and the earth thrown out being formed into a bank on one side, adds considerably to the depth of the ditch, and forms a tolerable fence. Ditches are made of various forms; but the sloping form is to be preferred, as it is not only constructed originally at less expence, but is more durable. But ditches of this description are more generally employed in conjunction with another kind of fence. The simple ditch, with a bank of earth, is a fence consisting of a sloping ditch, and of the earth taken from it formed into a bank on one side. A scarcement, or vacant space of six or eight inches broad, is left between the bank and the edge of the ditch, to prevent the loose earth from falling in and filling it up. The double ditch, with a bank between, is but rarely employed, excepting where hedges or trees are to be planted on the intervening bank. It affords a better fence than the single ditch, and it is highly useful as an open drain of lands on the sides of highways, where there is a considerable declivity towards the road. The field-ditch receives the waters from that side, and the road-ditch prevents it from being overflowed and injured. In dividing high from low, Inclosing.

flat lands, and especially where the high grounds have a sudden slope, the double ditch is extremely useful. The ditch on the side of the high ground preserves the lower fields from inundation in the time of heavy rains, and the ditch on the other side is a drain for the flat land. When ditches of this description are constructed near high grounds, or on the sides of high ways, the precaution of altering the direction of the furrows, or side ditches, by giving them a gentle curve a few yards from their junction with the main ditch, cannot be too strictly observed; otherwise the water falling into the ditch with the force of an unbroken current, is apt to undermine the bank, and wash away the loosened earth.

A fence composed of a sloping bank of earth, with a perpendicular facing of sod, is very useful in making folds for sheep or cattle, for defending gronnds adjoining to high ways, for laying off clumps or belts of planting in the middle or corners of arable fields, or for inclosing cottages, gardens, or stack-yards. In constructing this fence, the sod pared from the surface of the sloping ditch forms the front of the bank, and the earth thrown out forms the bank itself. When this kind of fence is employed for the purpose of a fold, the perpendicular front, as it presents a more formidable appearance, should be placed on the inside of the inclosure, but in general the bank is in the inside, and the front on the outside of the field. Fences of this description are to be regarded only as of a temporary nature, but may be employed as a useful substitute for paling where wood is dear, or for other materials for the shelter of young hedges.

The Ha-ha, or sunk fence, resembles the preceding in its mode of construction; but in this case the front or facing is composed of brick, dry stone, or stone and lime. The height varies according to the nature of the grounds, and other circumstances. Fences of this kind are chiefly suited for gardens and extensive lawns, for the purpose of preserving the prospect uniform and uninterrupted; but without a hedge planted on the top, the sunk fence scarcely affords any shelter.

The double ditch, with a hedge in front of each bank, is employed in different parts of Britain, and particularly what are denominated cold lands, from a prevailing opinion that a single hedge would not form a sufficient fence; and, besides, it is supposed the advantage of additional shelter is derived from a row of trees planted on the middle of the bank. But the expence of a fence of this kind, and the quantity of ground required being double, are serious objections to its use; and, besides, the bank in the middle is cut off by the ditches from the adjoining grounds, and the nourishment of the double hedge and the row of trees is limited to the insulated mound, so that they are liable to be affected by drought or frost.

Hedge fences are either formed of living plants or of dead materials. Dead hedges are constructed with the prunings of trees, of the tops of old thorn or beech hedges that have been cut over, and are chiefly employed and well adapted for the temporary purpose of protecting young hedges. In some cases dead hedges are the only fence; but being of a perishable nature, the necessary repair, after the first or second year, is attended with great expence. When the protection of a young live fence, planted upon the common surface, is the object of the dead hedge, it is made in a trench or furrow immediately behind, that the sheep or cattle grazing in the inclosure may be prevented from injuring it. When the quick fence is planted upon the side of a ditch, the dead hedge is generally made on the top of the bank.

Inclosing.

Dead hedges are variously constructed. In some, the thorns, or brushwood, of which they are composed, are cut into certain lengths, and fixed into the earth. These are called plain dead hedges. In other dead hedges, the upright stakes are let into the earth about twelve or fourteen inches, and fastened at the top with willows or hazels. The wattled dead hedge has strong upright posts, and is well known in Scotland by the name of *stake* and *rice*. But it has been justly observed, that fences of this nature are a very unprofitable substitute for a live hedge, for they are attended with the constant expence of repairs; and there are scarcely any situations where some species of living plants would not only grow and thrive, but the original expence would perhaps even be less than for these temporary constructions; and it may be added, that the live hedge growing annually stronger, would afford shelter to the inclosure, and become an ornament to the country.

Live hedges.—Various trees and shrubs have been employed, for the purpose of constructing live hedges; but it is a matter of great importance to select such plants as seem best suited to the soil and climate; and in this choice some aid may be obtained by observing the native trees or shrubs which thrive most vigorously, and attain the largest size, in particular climates, and on certain soils. But in situations where such plants do not appear, recourse must be had to experience, to ascertain what kind of plant is best suited to the soil and situation. The hawthorn, for instance, which has been often very injudiciously employed in such cases, is extremely ill adapted to lofty situations; but beech, birch, larch, and the Huntingdon willow, can be reared in a short time, and form good fences in hilly countries, or upon cold wet soils. The first three should be preferred when the soil is dry; and the willow, with the addition of poplars, may be successfully planted in wet and marshy places. In the low countries, or in less elevated upland situations, birch, poplar, alder, and Huntingdon willow, are best suited for cold, wet, and marshy grounds. Beech, crab, and some other plants, answer well on stiff clays; but on loamy, sandy, or gravelly lands, where the soil is dry, the white thorn, hazel, sweet-briar, and rowan tree, are most advantageously employed in the construction of hedges.

It rarely happens, whatever may be the quality of the soil, that it is equally suitable for the vigorous growth of every kind of plant; and, besides, the growth of different species of plants is seldom the same on the same soil, so that the certain consequence of different plants in the same hedge, is, to produce inequalities and defects. But although the soil were equally favourable to the growth of the different species employed, when planted separately, those of a climbing nature, as the ivy and honeysuckle, by twisting round the thorns or other plants

Inclosing. near them, in a short time entirely interrupt their growth. The different kinds of sweetbriar and brambles, have a similar effect; for in the end, by overshadowing and smothering the thorns, they never fail to produce an unseemly gap.

Preparation of the soil.—In planting hedges, by far too little attention has been paid to the preparation of the ground; from which it has often happened, that a stunted and useless hedge appears in a situation where a vigorous and excellent fence might have been reared. When it is intended to plant a hedge, the ground should, in every instance, be previously prepared by a complete summer fallow, for the destruction of weeds. A certain proportion of lime, dung, or compost, is next to be laid on the tract upon which the hedge is to be planted. The manure being properly mixed with the soil, a furrow is drawn with a common plough about the end of November, and in this furrow the plants are arranged, and the earth drawn close to their roots.

Time, &c. of planting.—Whatever be the nature of the plants of which the hedge is intended to be made, they should be put into the ground before the approach of winter, or early in the spring, before vegetation commences. The beginning of November, or any time during the month of January, is found to be the most proper season for planting thorns; and if they have been carefully removed from the nursery ground, with their roots uninjured, they are scarcely checked in their growth; and they shoot out more vigorously in the first year than in three or four years by less careful treatment.

When a hedge is made in the face of a ditch, bank, or wall, the plants are generally laid horizontally upon the surface, or upon a paring of sod taken from it. They are then covered to the length of from seven to nine inches from the root end, while three inches only are left to project. In this way the roots have sufficient room to stretch out, and the projecting part produces only two or three good shoots, which become healthy and vigorous. The future strength and value of the hedge depend on the number and vigour of the first shoots; so that no care should be omitted in preparing and manuring the soil.

In planting a hedge upon the common surface, a furrow of eight or nine inches deep is made with a common plough, upon the tract previously prepared; and that the furrow may be clean, the plough is twice drawn along it. A labourer then, with a bundle of plants, goes along the furrow, and drops them in handfuls of six or eight, at certain distances. Having finished 100 yards in this manner, he returns to the spot where he commenced, takes up the first handful, and places each plant in the bottom of the furrow, leaning against its perpendicular side, and at the distance of from four to six inches from each other. The whole plants being thus arranged, they are covered with the earth which has been turned up by the plough. He then sets a foot on each side of the hedge, and moving slowly along, treads the earth close to the roots of the plants, after which the operation is finished, by pointing the soil with a spade on each side. When the ground is properly prepared, a single labourer is capable of planting several hundred yards of thorns, or other hedge plants, in a day. In some cases the dibble is employed in planting hedges; but by this practice the fibres of the roots are greatly injured, by being pressed together, or, if they are pruned, their growth receives a severe check.

Inclosing. *Age and size of plants.*—It is a common practice to plant thorns of three years old, and it seldom happens that they are allowed to exceed this age; and, with proper preparation of the soil, regular weeding and digging, a good fence is obtained; but it cannot be doubted, that plants of six or seven years old would afford an earlier and better fence. When plants of this age are employed, the precaution of preserving the roots entire should be particularly observed. It is no small advantage to arrange thorns or other hedge plants according to their size and apparent strength, because plants of the same size and strength keep pace with each other, and the growth of the whole is regular and uniform; but when strong and weak plants are brought together, the stronger soon outgrow and overtop the weaker, so that inequalities and gaps soon make their appearance. By assorting hedge plants in this manner, the strongest and healthiest may be planted upon the poorest part of the soil, in the line of the fence, and the smallest and weakest upon the richer and more fertile parts. By this management, a strong and equal hedge may be reared through the whole line.

Pruning before planting.—The practice, which is by no means uncommon, of pruning the tops, and cutting off the greater part of the roots of thorns, is extremely injurious to their future progress and growth; and it is also not unusual to take them up in great quantities, tie them up in bundles, and allow them to remain in this state for many weeks. It is not generally known, that plants derive their nourishment from the earth, by means of the extremities of the small fibres, and when these are cut off, the growth of the plant is completely interrupted, till a new set of fibres shoot out. To avoid this and other injuries, thorns should not be raised from the nursery ground till the day on which they are to be planted out; and, instead of the spade, they should be taken up with a dung fork, having strong round prongs; and while the roots are carefully separated from the soil, the smallest fibres should be preserved. The top of the plant only, if that be necessary, should be pruned.

Weeding hedges.—Whatever attention may have been paid to the preparation and planting of a hedge, its vigorous growth depends greatly on its future treatment; and one of the first requisites in the management of a hedge is weeding. Annual weeds are removed by a slight scuffle with a hoe, and the operation is to be repeated as often as a new crop appears. Perennial or biennial plants, which have strong roots, are most conveniently eradicated by means of the dung-fork already recommended for raising thorns from the nursery. This implement is preferable to the spade, because, without cutting the roots of the hedge, it loosens the ground, to allow the weeds to be removed. The first weeding of a young hedge should be performed early in the spring. Loosening the earth at this time is also advantage-

Inclosing. ous, when the roots begin to spread and extend themselves. Annual cleanings and loosening of the soil about the roots are essentially necessary, to promote the growth and vigour of every hedge. But, besides this advantage, it is not less necessary to keep hedge banks free from weeds on account of the adjoining fields, which are soon overrun by plants springing up from seeds produced in the hedges or highways. It would, therefore, be a public benefit to have the whole weeds round the line of fences, as well as in the high-roads and uncultivated spots of ground, cut down before the time of flowering and running to seed.

Pruning hedges.—Much of the future value and beauty of a hedge depends on the proper pruning and after-management. But concerning the mode of pruning, and the season of the year when it should be performed, great diversity of opinion prevails. To have the best and most useful hedge, it should be pruned in such a way as to be broad at the bottom, and should taper gradually towards the top. The summer season, the most improper that can be chosen, is often selected for the operation of pruning, when the plants are full of juice and vegetation is in its most vigorous state, in preference to the commencement of spring or the end of autumn, when they are less liable to injury from bleeding. After the first pruning, already noticed, when the hedge is planted, it should scarcely be touched with the knife or shears for some years. When the main stem of a thorn, or indeed any other plant, is cut over, it sends out lateral shoots, or a number of small stems, at the place where it is cut; and if this injudicious operation be repeated once or twice every year, each small stem is again subdivided, and the upward progress of the hedge is completely interrupted. A hedge thus treated cannot be recovered but by cutting over close to the ground, when healthy and upright stems shoot up vigorously, and soon form a sufficient fence.

The first general rule that can be given for the management of a young hedge, is to leave the main stem untouched till it has reached the heighth of five or six feet. Whatever pruning it has received should be entirely confined to the side branches, those next the root being left pretty long and tapering gradually towards the top. The side branches thus pruned send out new shoots from their extremities, which become so thick as to fill up all the interstices, while the main stems are left untouched, and shoot upwards to the necessary height. Regular switching with a hedge bill, is all that is afterwards required in the proper management of such a hedge.

Cutting down old hedges.—When hedges are neglected, they shoot up to a great height, become open below, and often useless as a fence. The only method of recovering hedges treated in this way, is by cutting them down to obtain a new set of shoots from the stumps. In fields surrounded by such hedges, if they are alternately in pasture and tillage, the proper period for cutting them down is when the field is under corn crop. Different methods are recommended for performing this operation. In the first, the hedge is cut over a yard above the surface, and is left in that state; this mode of treating a hedge originally good, fully answers the purpose, and in a few years, with proper management, it becomes an excellent fence; but if there has been a deficiency of plants, numerous gaps appear, which it is extremely difficult to fill up. But it is a more serious objection to a hedge being treated in this way, that live stock attempting to leap over it, run the risk of being destroyed by the sharp points of the stakes. Inclosing.

A second mode of managing an old hedge, is, to cut over a fourth-part of the hedge to the intended height of the fence, and to bend down and warp the remaining three-fourths with the upright stems. In this way the gaps and vacant places below are effectually filled up, and, with proper attention, a good fence is soon obtained.

A third way of treating old hedges is, by cutting them close to the surface; when there are no gaps, this method answers sufficiently well, but otherwise the defect soon appears. This method is inferior to the one last mentioned, but is preferable to the first; for the young shoots from the stumps, by being near the ground, in some measure supply the deficiencies occasioned by the want of original plants.

The last method of managing old hedges is to cut them down even with the surface, and to cover the stumps completely with earth from the ditch or the road side. By this treatment every single root sends out a great number of young vigorous shoots, each of which branches out from the stump below the surface, sends out roots, and acquires an establishment for itself. In this way the bottom of the hedge becomes so thick, that no kind of animal can force its way through it. In the future management of such renovated hedges, the same directions as for young hedges must be attended to, and particularly the precaution of saving the upright shoots till the hedge has attained the proper height, should be strictly observed. The proper season for cutting over old hedges, as well as for pruning and switching them, is either at a late period in the autumn, or very early in the spring.

Filling up gaps in hedges.—To prevent the occurrence of gaps in a hedge, it should be carefully examined about the end of the first autumn after it is planted, and dead and decaying plants should be removed, and replaced by the strongest and most vigorous that can be found. With such attention for the first two or three years, the hedge becomes uniformly thick and strong, and few defects appear. But when old hedges are to be cut down, some means must be adopted to fill up the open spaces. The common method is, to select a strong plant next to the gap, and, with a gentle stroke of the hedge-bill to bend it across the opening, and entwine it with the thorns on the opposite side. When the old hedge is cut down close to the earth, gaps are effectually filled up by digging the ground pretty deep with a spade, and taking one of the strongest plants on each side of the opening, that have been left uncut, removing the earth from the roots, so as to loosen them, that they may be bent down and laid close to the earth in the gap. They are then fastened down with wooden hooks, and covered throughout their whole length with earth. Young shoots soon appear from the old stems to fill up the vacancy. This method answers well with a hedge that is cut over close to the surface, but when

Fences.

it is cut at the height of three or four feet, a temporary paling, to protect the young shoots till they become a sufficient fence, must be erected.

The gaps of a hedge which has been cut over at the height just mentioned, may be effectually repaired by planting old thorns, when such can be obtained, the earth in the gap being previously stirred up and manured. The end of autumn, or the beginning of winter, is the proper season for this operation.

Strong beeches have been successfully employed to remedy the defects of grown up hedges. The plants should be six or seven feet in height, and supported by a couple of pieces of coarse paling, placed across the opening. Beeches of this description, planted early in the winter, suffer no check, and shooting out vigorously in the spring, fill up the opening during the first season.

It is a common practice to fill up gaps in hedges with dead wood, such as the prunings, and other brushwood; and for the same purpose stones are sometimes employed: but the use of such matters is at best only temporary, while they serve to continue and enlarge the opening.

Plashing hedges.—In performing this operation, the old hedge is first cleared of all dead wood, brambles, and other straggling plants, leaving along the bank the straightest and best growing stems of thorn, hazel, elm, oak, ash, beech, &c. about five or six in a yard; but where there are gaps, a greater number is left. The ditch is then repaired, and the earth thrown on the bank. Such of the stems left in cutting the old hedge as are found growing in the line of the new hedge, are cut off three feet from the top of the bank, and are employed as hedge stakes to the new hedge. This is an essential part of the practice; for these stakes being immoveable, and never rotting, prevent the new hedge from falling, or inclining to any side. Dead hedge stakes, such as sallows, or willows, which may grow, are driven into vacant spaces. The wood left standing in the remainder of the line is then plashed down; the stem is cut in two places; it receives one stroke near the ground, and the other about ten or twelve inches higher. The cuts should be of sufficient depth to admit part of the wood between the two being slit out, the stem itself being supported by little more than the bark, or about a quarter of its first size. It is then laid along the top of the bank, and interwoven with the hedge stakes. In plashing hedges, the cuts should be directed upwards, instead of downwards, by which the heart of the plant is exposed to the weather. In all cases where old hedges are either cut over or bent down, the ground on each side, as soon as it can be accomplished, should be well dug, cleared of weeds, and the earth laid up to the roots of the plants, by which means they soon send out luxuriant shoots.

Black thorn hedge.—A cheap fence may be constructed with this plant, in exposed situations, where the white thorn would not thrive. Full grown sloe, or black thorn plants, are set pretty thick, and mixed with hazel, withy, large briar, &c. the tops being cut off to the height of three feet, on a bank raised from two to three feet, with ditches of sufficient depth; but this method should only be adopted in bleak situations. In such situations, however, the black thorn, which abounds in most places, with the assistance of the briar, soon forms a close and impervious fence.

Beech hedge.—As the beech plant seems to resist the effects of sea air, it is found suitable for such situations where the white thorn does not thrive. The bank for a beech hedge should be six or seven feet high, and four or five wide at the top. The young plants are set in two or three rows, at the distance of a foot from each other, and sufficiently thick in the rows. A ditch is seldom required, but the bank or mound is supported by a low stone wall. The beech grows rapidly, and soon forms an excellent and beautiful fence; and, besides, it affords shelter to a late period of the season, while the profit is considerable, from the alternate cutting of one of the rows, when they come to maturity, while the others are plashed or trimmed, yielding wood for fuel or other purposes. This kind of hedge is attended with one inconvenience, that it requires a large quantity of earth for the bank.

Furze hedges.—In similar situations, furze, or whins, are often employed for a fence. By sowing the seeds thick, on high and broad banks, with ditches on the sides, the young furze grows easily and quickly. To guard against the thinness produced by the decay of the old parts of the plant, the best method is to cut them close down, first on one side and then on the other, every two or three years. The broad bank recommended admits of this management, and a fence always remains on one side or the other, in some degree of perfection. In situations where fodder is scarce, the bruised cuttings may be employed as food for animals. But a hedge of this kind ought only to be adopted as a substitute in places where other plants do not succeed; for it requires a large space of ground, and the seeds scattered over the inclosures soon fill them with plants, which are not easily eradicated.

Diseases of hedge plants.—On certain soils, as on cold wet clay, the white thorn, as well as other woody plants, are apt to be covered with moss, which greatly impedes their growth, and, as it increases, entirely destroys them. In planting young hedges, it has been recommended to prepare the soil by manuring it; and if a sufficient quantity of lime be incorporated with the earth, the young hedge is secured from this malady. To recover old hedges from this evil, and render them good fences, they should be cut down close by the surface, cleared of weeds, and the earth well dug to the extent of half a yard on each side. After this operation, which should be performed about the end of autumn, the spaces which have been dug are to be well limed on the surface, and remaining in that state during the winter, the earth should be dug again early in the spring, and the lime well mixed with the soil. Where this method has been properly practised, the plants push out vigorous shoots, which soon form good hedges, and the moss no longer appears. The use of lime in the same way is recommended as a certain remedy to destroy moss on other kinds of trees.

Hedge-row of trees.—Hedge-rows, planted in the direction of the live fence, are recommended by some as affording shelter and beauty to a country; but al-

Fences.

though this practice is by no means uncommon, especially in England, it is objected to by others, because it deprives the fence of part of its nourishment, and greatly injures the plants by the shade, as well as by the drop, in rainy weather. Where hedge-rows accompany stone walls, and when they attain a considerable size, they are shaken by strong winds, by which the wall is loosened and cracked, and requires constant repair. But the inconvenience is not confined to the fence only. The drop and shade of such trees, when the branches extend to any great length, are also injurious to the corn and herbage crops. But it rarely happens that trees planted in this way arrive at any great size to afford such emolument to the proprietor as may counterbalance the disadvantages with which they are attended. Hedge-rows, therefore, may be considered more as an ornamental than an useful improvement.

Compound hedge fences are of different kinds, as a single hedge and ditch, with or without paling; hedge and bank; hedge with post and rail; hedge and wall fence, and some others; and paling or timber fences are constructed either with simple nailed, jointed, horizontal paling; upright lath paling; horizontal paling of young firs; paling of growing trees, or rails nailed to growing posts, and others of the same description:—but for a particular account of such fences, we refer to Dickson's System of Agriculture, or to the General Dictionary of Agriculture and Husbandry.

Wall-fences are either constructed of dry stone, of stone and lime, of brick, or of turf.

Dry-stone wall.—Walls of this description are sometimes constructed by common labourers, with round stones, collected from the fields, and coped with sod. Sometimes they are made with quarried stones, brought somewhat into shape. Of fences of this description, the Galloway dike, so called from being extensively used in that district of Scotland, seems to be in most repute.

Galloway dike.—This kind of fence is not uncommon in many parts of Scotland, and in some parts of England; and it seems well calculated for inclosing high grounds pastured with sheep. It is regularly and compactly built with dry stones, in the same way as a dry-stone wall, with a broad base, and tapering gradually upwards to the height of two feet, or two feet and a half. The building is then levelled with a course of flat stones, resembling a coping. These flat stones project two or three inches over the wall on each side. A course of rugged round stones succeeds, and they are placed upon each other in a way sufficiently secure for the stability of the building; but so open as to allow a free passage to the wind and light. The rough open part of the building is usually raised three feet above the regular part, and gradually tapers upwards till it terminates in a top of nine inches broad; every course of the rough stones being smaller than that immediately below it. The tottering appearance of this wall prevents every kind of animal from approaching it; so that, where stones fit for the purpose are abundant, it becomes a valuable fence. In many places where the fields are covered with large stones, the expence of a wall of this kind but little exceeds the mason work; but the expense must vary according to the price of labour, and the facility or difficulty of procuring stones. This fence answers equally well, if not better than more expensive fences, in most situations, where the confinement of the stock, or the protection of a crop, are the principal objects. But it affords neither shelter nor ornament to the country; so that it seems most eligible in lower districts, where land is valuable, and little shelter is required.

Stone and lime walls.—To render walls of this kind durable, they should have a good foundation, deep enough to prevent the effects of frost, with a broad base, gradually tapering upwards. Next to hedges, this is the most durable fence; but it is expensive, and possesses few advantages over the dry-stone wall. Stones from the quarry are always to be preferred to land stones. Like other stone fences, it ought to be secured at top with a substantial coping of stone and lime. Flag-stones, inclining towards each other, and meeting at the top, with the intermediate space filled with small stones and mortar, forms a most durable coping, which, from its wedge-like shape, and solid, impenetrable surface, seems well calculated for the preservation of the building. The end of spring, the summer months, or the early part of autumn, are the best seasons for such operations.

Stone and clay walls.—In the construction of such walls, the clay is employed as a substitute for lime; and in the dry stone wall, lipped with lime, the difference from the ordinary wall, in having about two or three inches on each side lipped with lime, which gives it the appearance of an entire building of stone and lime; but it is found to be little more durable than the common dry stone wall. Walls of this latter description are sometimes dashed with lime after the work is finished; which adds something to their appearance, but contributes little to their utility. Dry stone walls are primed and harled, by filling up every vacant space on the outside of the building, and harling afterwards, which gives a finished appearance, and produces a durable fence.

Frame-walls.—The construction of such walls is accomplished, by preparing a frame of deal-boards, of the intended width and height of the fence. A foundation is dug; the frame is placed upon the line, and filled with stones of all kinds, collected from the fields. When the frame is filled to the top, liquid mortar is poured in to fill up the interstices, and the whole remains in that state till the mortar has acquired a sufficient degree of firmness to give stability to the building. This is accomplished in a day or two, during the warm and dry weather of summer; the frame is then removed, carried farther along the line, and the same operation is repeated. In this way the whole line of fence is gradually completed, and, with well-tempered lime, and proper attention to incorporate it with the stones, the wall presents a smooth surface, with a firm and substantial appearance.

Every kind of stone-wall possesses considerable advantages. The inclosure is completed at once; little space is occupied, so that a considerable portion of land is saved; and even that part near the sides of stone walls, which is usually waste, may be profitably employed in raising grain, potatoes, or other vegetables. But these advantages are accompanied with some defects. The most substantial fences of this kind are more or less perishable, according to the materials employed and the mode of construction. After a certain time, the attention and expense to keep them in repair are considerable. They afford but little shelter, and are rather a deformity than an ornament to the country.

Chap. III. Of Soils.

Soil is the layer of loose, earthy matters, which constitutes the upper covering of the globe, affords a station to the roots of innumerable tribes of vegetables, and supplies them with nourishment to promote their growth and bring them to maturity. It consists of the primitive earths which enter into the composition of the prevailing strata or rocks, from the disintegration of which it is obviously formed. The succeeding layer, on which the vegetable soil reposes, whatever be its nature, whether it be composed of less coherent or more solid materials, is usually distinguished by the name of under-soil, or *subsoil*. In treating this subject, the formation, composition, and classification of soils may be considered.

Sect. I. *Of the Formation of Soil.*

The formation of soil is a beautiful natural process, which is accomplished by the combined influence of moisture and vegetable action on the solid strata of the globe. The changes which take place in this process succeed each other with more or less rapidity, according to the nature of the rocks, and the power of the agents which operate in their decomposition. In a warm country, and a moist climate, where vegetation is powerful and vigorous, it proceeds with astonishing rapidity; but in the colder regions of the earth, it advances with slower and more progressive steps. But, whatever be its progress, the hardest rocks, as well as those of less durable or less coherent materials, are subject to disintegration and decay, and contribute to the formation and increase of soil.

First process.—It is not difficult to trace the steps of this process, by observing what is daily going on around us. A bare rock, when it is uncovered, or a mass of stone which has been lately dug from the quarry, when fully exposed to the air, soon loses its fresh appearance, and assumes a different aspect. When the change that has taken place is investigated, it is found that the surface of the stone is covered with a thin crust, of a substance very different in its nature from the stone itself. A closer inspection shews that this crust is a vegetable production, belonging to the tribe of plants known by the name of *Lichens*, and supposed, perhaps from ignorance or inability to examine them, to be less perfect in their structure than other plants. The seeds of plants of this description are extremely minute, easily wafted about by the wind, and, floating in the atmosphere, attach themselves most readily to those bodies which are somewhat moist. Porous rocks, which are most apt to absorb moisture from the earth or from the air, are the first on which lichens make their appearance. By means of this vegetable covering, a larger portion of moisture from the atmosphere is absorbed, and a smaller portion of what rises through the rocky mass from the earth is lost by evaporation. This affords additional nourishment, and increases the power of vegetation. A thin layer is soon detached from the surface of the rock, and reduced to the earthy form. The first vegetable productions, in the changes of the seasons, decay; and hence the first thin stratum of soil is formed by the decomposition of the vegetable matter, and the disintegration of part of the mass of stone on which it was produced. Plants of a larger size, and more vigorous growth, whose seeds are carried about in the air, find a fit receptacle in this mixed mass of matter for their vegetation and growth. They, in their turn, decay, and contribute a fresh portion of vegetable substance, while another accession of earthy particles, derived from the stone, is made to the general mass. Insects and worms, which make their abode in the earth or on plants, in the progressive changes to which they are subject, and in the various stages of their existence, deposit animal remains in the places which they frequent, serve also to increase the quantity of organized matter in the new soil. Tracing the progress of the formation of soil in this way, we may see how a thick bed is prepared, which shall, in time, be fit for the reception of the largest plants.

Every kind of rock, even of the densest and hardest nature, is subject to this change. The purest rock-crystal when exposed to the weather, in no long period is deprived of its brilliant lustre and fine polish; but the extent and rapidity of the change correspond with the nature of the rocky mass and the heat and moisture of the climate. In the warmer regions of the earth, the surface of a bare rock is soon converted into friable, earthy matter, covered with verdure, and clothed with trees; but in colder climates, or in more elevated situations, the process is slower as well as more limited. The vegetables which spring up are of smaller magnitude, and of a diminutive growth, and thus afford a more scanty supply to the production of soil.

Diversity of soil.—The diversity of earthy matters contained in the soil, depends on the nature of the constituent parts of the rocks from which it is derived. Rocks in which the prevailing constituent is siliceous earth, afford a sandy soil; these rocks in which alumina, or pure clay, is predominant, yield a clay soil; lime abounds in the soil which is formed in the vicinity of limestone-rocks; and the just proportion of these earths, which may be considered as the basis of a good soil, is derived from those rocks in which they naturally exist.

Carse soil.—But the soil, as it is formed by the disintegration of rocks, does not always remain on the spot from which it originated. It is carried by rains and floods, from the higher to the lower ground, where it is deposited, and, in a succession of ages, forms a thick bed. When the earthy matters are swept away by rivers with a slow current, they are deposited on their flat banks, or at wide estuaries. In this way some of the richest soils have been formed. The fertile lands at the mouth of the Nile, and

Of Soils.

the flat grounds in the vicinity of the Forth and the Tay in Scotland, well known by the name of *carse lands*, are of this description.

Gravelly soil.—Gravel, which abounds in many soils, and constitutes entire beds, derives its origin from those rocks whose lofty precipices are exposed to the weather; but especially from such rocks as contain many fissures and cavities, and admit and retain water. This water, when it is near the surface, is frozen during the winter, and, by its expansive force in the state of ice, tears off and throws down immense masses of the rock. These masses, broken down in their fall, are reduced to pieces of still smaller magnitude by the current of rivers, or the agitation of the waters of lakes, or of the ocean. In the progress of those changes which the face of the earth everywhere exhibits, the river changes its course,—the sea recedes,—the lake is dried up,—and the bank of gravel becomes dry land. The seeds of vegetables fall on its surface,—grow up, and decay; they are succeeded by other generations, which run the same course; a portion of earthy matter is obtained from the stones on which the vegetable remains are deposited, and being mixed with the loose stones, forms a gravelly soil.

Moorish soil.—The nature of the climate, and water stagnating in low grounds, have a powerful effect in producing a diversity of soil. In elevated situations, the chilling influence of cold permits plants only of a coarse and hardy character to spring up; when they die, the same influence retards or interrupts their complete decomposition; and in such places the soil consists of a mass of half-decayed roots and stems of different species of heath and *carex*, or sedge-grass, with which it is almost entirely occupied. This is the origin of heathy or moorish soils.

Mossy soil.—In places where water stagnates, a different tribe of plants is produced. The bog-moss, or *sphagnum palustre*, first makes its appearance; a new race of the same species succeeds; other species and plants of a different character find a convenient station in the floating mass; and, from the accumulation of innumerable generations of various kinds of vegetables in a state of imperfect decomposition, peaty or mossy soil derives its origin.

Saline matters in soil.—Besides the ingredients already mentioned, which may be considered as the base of soils, other substances enter into their composition. Some of these, as magnesia, which is sparingly met with in soils, and certain metallic matters with which they are frequently impregnated, originally existed in the strata, from the disintegration of which the soil is formed. Saline substances, which are also sometimes found in soils, have the same origin, but are occasionally deposited by the water of springs, as it filtrates through the earth.

Subsoil.—The stratum which immediately supports the soil in which vegetables grow, is distinguished from its relative position by the name of *subsoil*, or undersoil. It sometimes happens, but rarely, that the rock which furnished the materials for the soil constitutes the subsoil; but it consists more frequently of a bed of gravel, or clay, or sand. A knowledge of the nature and character of the subsoil is of no small importance in conducting improvements in agriculture. It is often a guide to the means to be adopted in draining; and in tillage operations, when it is within reach of the plough, it may be avoided, or partially turned up, as the ingredients of which it is composed, when mixed with the soil, seem to be salutary or injurious.

Of Soils.

Sect. II. *Of the Component Parts of Soils.*

The ingredients of which soils are composed, are certain combinations of some of the primitive earths, with organized matter in a decomposing state, along with a portion of iron, and some saline compounds. The proportion of these matters is extremely variable, and from this arises the endless diversity of soils. The predominant earths in soils are, alumina or pure clay; silica, or pure sand; lime, or calcareous earth; and, more rarely, magnesia.

Alumina, or clay, when in a state of purity, is in the form of a white powder; it adheres strongly to the tongue, is insoluble in water, but soluble in acids, and in watery solutions of the fixed alkalies. It is the prevailing earth in clay soils, in which it is generally of a reddish colour, from an impregnation of the oxide of iron.

Silica, or the earth of flints, or pure sand, when in a state of perfect purity, is also in the form of a white powder. It is infusible in the fire, and insoluble in water, and almost all the acids. Sandy and gravelly soils, and hard stony lands, are chiefly composed of silica.

Lime is obtained from the burning of limestone, in which state it is known by the name of quicklime. As it exists in soils, it is commonly in combination with carbonic acid, or fixed air. It is also in the form of a white powder, when it is perfectly pure. Chalk is limestone, with a slight degree of coherence; and marble is the same substance in its most compact form. Gypsum, or plaster of Paris, is lime in combination with sulphuric acid, or oil of vitriol; and phosphate of lime is a compound of lime and phosphoric acid.

Magnesia, in a state of purity, is a white, light powder, which is soluble in acids, but not in alkaline solutions. It is a rare ingredient in soils; but when it appears, it is in combination with carbonic acid, or with some of the earths.

The saline matters which have been detected in soils are, common salt, Epsom salt, muriate and sulphate of potash, nitrate of lime, and some of the alkalies; but they exist in very small quantities, and their occurrence is rare.

Rust of iron, or ochre, or oxide of iron, is met with in almost every soil; but in the red and yellow clay soils, and the red and yellow siliceous sands, it is in greatest abundance.

Vegetable and animal matter, in a state of decomposition, forms an essential ingredient in all good soils. Vegetable matter exists in very different states, contains a large proportion of carbonaceous substance, and yields no volatile alkali. It is the chief ingredient in peats, and is abundant in rich moulds. The state of animal matter in the soil is as different as the substances from which it is obtained. It usually contains less carbonaceous substance than vege-

Of Soils.

table matters; and, when exposed to heat, affords ammonia, or volatile alkali, and carbonic acid. It is abundant in soils to which manure has been lately applied.

A fertile soil in the vicinity of Turin, analysed by M. Giobert, contained, in a pound weight, from 20 to 30 grains of extractive matter, which flamed and burned, and 70 grains of water, and about 19 grains of air, one-third of which was carbonic acid, and the rest heavy inflammable air. It yielded no volatile alkali. The earths existed in the following proportions in 100 parts:

Silica	from 77	to 79
Alumina ——	9	— 14
Lime ——	5	— 12

In a less fertile soil, the proportions were found to be,

Silica	from 48	to 80
Alumina ——	7	— 22
Lime ——	6	— 11

And in soils accounted barren, the proportions appeared to be,

Silica	from 42	to 88
Alumina ——	20	— 30
Lime ——	4	— 20

But, if these analyses be correct, the difference between rich and poor soils must depend more on the proportion of organized matter existing in them, than on the diversity of the earthy ingredients.

The more improved state of chemical science, and the ingenious researches of Sir Humphry Davy, have enabled that distinguished philosopher to throw a clearer light on the nature and properties of soil. The following are the results of his analysis:—A good turnip soil from Norfolk afforded eight parts out of nine of siliceous sand. Of the finely divided matter, 100 parts consisted of,

Carbonate of lime -	63
Silica - - -	15
Alumina - - -	11
Oxide of iron - -	3
Vegetable and saline matter	5
Moisture - - -	3

A soil in which oaks grow vigorously, taken from a field in Sussex, was composed of six parts of sand, and one part of clay and finely divided matter. A hundred parts of the entire soil, analyzed, yielded,

Silica - - -	54
Alumina - - -	28
Carbonate of lime -	3
Oxide of iron - -	5
Decomposing vegetable matter	4
Moisture and loss - -	6

An excellent wheat soil from Middlesex afforded three parts in five of siliceous sand. The finely divided matter was composed of

Carbonate of lime - - -	28
Silica - - - -	32
Alumina - - -	29
Animal or vegetable matter, and moisture	11

In his remarks on these results, Sir Humphry Davy observes, that the first soil examined possessed the least, and the last the greatest cohesive property; that the finely divided matters, in all cases, give tenacity to the soil, and this quality depends on the proportion of alumina; and that a small quantity of finely divided matter fits a soil for turnips or barley, 11 parts sand out of 12 yielding a good crop of the former; that a much larger proportion of sand induces absolute sterility, as in the soil of Bagshot-heath, which has no vegetable covering, 400 parts heated red yielding 380 parts coarse siliceous sand, 9 parts fine siliceous sand, and 11 parts impalpable matter, which was a mixture of ferruginous clay and carbonate of lime; that the vegetable or animal matters, when finely divided, give coherence, softness, and penetrability; that none of the ingredients of a soil ought to be in too great proportion; that a soil composed entirely of impalpable matters is unproductive; that none of the earths in a state of purity, as alumina, or silica, or carbonate of lime, or of magnesia, is capable of supporting healthy vegetation; and that no soil whatever is fertile when it contains 19 parts out of 20 of any of its ingredients.*

Analysis of soils.—It would be of little use to the practical agriculturist, who is not always an experienced chemist, to enter into a minute detail of the method of analysing soils. For this information we refer to CHEMISTRY, or to Sir Humphry Davy's work already quoted; and we shall here notice some of the simpler processes from which a knowledge of the constitution, character, and more essential properties of soils, may be obtained.

In whatever way a soil is to be examined, whether by a ruder, or a more minute and accurate method, specimens of it should be collected from different places of the field, and two or three inches below the surface; and it should be carefully observed whether these different specimens possess similar properties. On extensive plains, the whole of the soil is found to be pretty uniform in the nature and proportion of the ingredients of which it is composed; but in vallies, and near the beds of rivers, which are supplied with materials of the soil from the higher grounds, and these being very different in their nature, great diversity of soil prevails. One part of the field is covered with a calcareous soil, and another part is siliceous. The specific gravity of a soil is an indication of the quantity of organized matter which it contains; for such matter is most abundant in lighter soils. To ascertain the specific gravity of soil, an equal bulk of water and of soil may be introduced into a phial of a determinate capacity. If a bottle containing 400 grains of water be half filled with that liquid, and if the remaining half be filled with the soil to be examined, and if the bottle gain 200 grains of weight more than when it is entirely filled with water, the specific gravity of the soil is double that of water, or 2. The colour, feel, and some other physical properties of soils, may in some measure lead to a knowledge of their composition. A siliceous soil is rough and hard to the touch, and when rubbed on glass scratches it. A red or yellow colour denotes a ferruginous soil; and softness is one of the characteristics of a calcareous soil.

* Elements of Agricultural Chemistry, 154.

Of Soils.

The power of absorbing and retaining heat and moisture, seems to be closely connected with the fertility of the soil. Certain soils are more easily heated than others, and when brought to the same degree of heat, cool more rapidly. A soil of a stiff white clay is heated with difficulty; and from the moisture it contains, retains the heat but for a short time. A chalk soil is also heated with difficulty; but, containing less moisture, the heat is retained longer. A black soil, in which soft vegetable matter is predominant, is most heated by the sun and air. Deep coloured soils, and such as contain a large proportion of carbonaceous and ferruginous matter, exposed to the sun, acquire a higher temperature than soils of a pale colour. A rich black mould, containing nearly a fourth of vegetable matter, exposed to sunshine, increased in temperature, in the space of an hour, from 65° to 88°; but a chalk soil, under similar circumstances, was heated only to 69°. The mould being removed into the shade, where the temperature was 62°, in half an hour lost 15°; while the chalk soil, in the same situation, lost only 4°. A cold fertile soil, and a cold barren clay, being previously dried, were heated to the temperature of 88°, and afterwards exposed to a temperature of 57°; the brown soil lost in half an hour 9°, while the clay had lost only 6°. An equal portion of the clay, containing moisture, was heated to 88°, and then exposed to a temperature of 55°; in a quarter of an hour it gained the temperature of the room. In conducting these experiments, which were made by Sir Humphry Davy, the soils were placed in small tinplate trays, two inches square and half an inch in depth.

Absorption of moisture.—The temperature of the soil, or its power of combining with and retaining heat, is greatly modified by the property of absorbing and retaining moisture; and the power of the soil to absorb water, depends, in a great measure, on the state of division of its parts; for the more they are divided, the greater is its absorbent power. This power is greater in vegetable than in animal substances; the latter possess it in a higher degree than compounds of the earths, and a considerable diversity prevails in the different proportions of the earths themselves.

The fertility of a soil depends much on its power of absorbing water from the atmosphere. Soils possess this power in very different degrees, and it is always greatest in the most fertile soils. Experiments can be easily made to ascertain this property; so that it affords a simple method of determining the fertility or barrenness of land. We shall quote the experiments of Sir Humphry Davy on this subject. 1000 parts of a rich soil from Ormiston in East Lothian, containing more than half its weight of finely divided matter, of which 11 parts were carbonate of lime, and nine parts vegetable matter, were dried at the temperature of 212°, were exposed for an hour to air at 62°, and saturated with moisture, and gained 18 grains. 1000 parts of a fertile soil from Somersetshire, treated in the same way, gained 16 grains; 1000 parts of a soil from Essex gained 13 grains; 1000 parts of fine sand from Essex gained 11 grains; 1000 parts of the soil of Bagshot-heath increased only three grains in weight *.

Proportion of organised matter ascertained.—An easy method of discovering the comparative proportions of organised matter in soils, is recommended by Dr Coventry, in his Lectures on Agriculture. This method consists in the simple process of deflagrating a certain quantity of the soil with nitre. In conducting the experiment, a determinate quantity of nitre is fused in a crucible, and while in that state the dry soil is projected upon it, in divided portions. The addition of the soil is continued till the deflagration, or sudden inflammation, which takes place when any carbonaceous matter comes in contact, ceases. Suppose it requires one ounce of a fertile soil to produce this effect, and that it requires two ounces of a different soil to produce the same effect, it follows that the latter soil contains only one half the proportion of carbonaceous matter which exists in the former, and therefore it must be greatly inferior in fertility.

Uses of earthy matters in soils.—Besides affording a station to plants, the earths which enter into the composition of soil have a kind of mechanical action in retaining water, and supplying it in proper proportion to their roots; they also tend to the equal distribution and supply of the vegetable and animal matter for their nourishment. But there seems to be some degree of chemical affinity between the earths and the earthy carbonates, and some of the principles of vegetable and animal substances. If an acid solution of alumina or pure clay be mixed with a solution of soap, the alumina unites with the oil of the soap, and forms a white powder, which sinks to the bottom of the liquid. When pipe-clay or chalk is boiled with the extract of decomposing vegetable matter, the compound formed renders the decomposition and solution of the vegetable matter more difficult. Siliceous sands have little effect in this way; but the soils which have the greatest chemical power in preserving manures, are those in which alumina and carbonate of lime are the predominant earths. Such soils are well characterised by the name of rich soils; while sandy soils are properly denominated hungry, because they have little or no affinity for the organised matters which are soon carried off by water or dissipated in the atmosphere. The black and brown rich vegetable moulds are supposed to be combined with a peculiar extractive matter, derived from the decomposition of vegetables. This matter is slowly taken up by water, and appears to be one of the chief causes of the fertility of the earth †.

Effects of the sub-soil.—Soils which repose immediately upon a stratum of rock or stone, become much sooner dry by the process of evaporation, than when the sub-soil is of clay or marl. The contiguity of the rocky strata to the soil, is supposed to be one of the principal causes of the remarkable fertility of the land in the humid climate of Ireland. A sub-soil in which clay predominates is sometimes highly beneficial to a sandy soil, in aiding its deficient absorbent power, and supplying the moisture which is lost by evaporation and the consumption of plants; and, on

* Elements of Agricultural Chemistry, p. 161. † Ibid. 262.

the other hand, the excessive degree of absorbent power in a soil, is often corrected by a sub-soil of a sandy or gravelly nature. In calcareous countries, where the surface appears to be a species of marl, the limestone is only a few inches from the soil; but the contiguity of the rock impairs not its fertility, although a less absorbent soil would, in such circumstances, be rendered sterile. This is finely exemplified in the appearance of the sand-stone and limestone hills in Derbyshire and North Wales during the summer season; the grass of the former usually exhibits a brown and parched aspect, while the latter are clothed with a rich verdant covering.

Plants indicate the nature of the soil.—The method of judging of the nature of soil, from the growth and character of plants, which is sometime had recourse to by practical persons who have little knowledge of botany, might, we apprehend, be greatly improved, by more extensive and more accurate observation. When plants, which are the natural productions of a good soil, appear in a healthy and flourishing state in other situations, it may be concluded that there is a near resemblance in the two soils. Thus, for example, the thistle of different species is a mark of a good soil; the dock grows in an inferior soil, of the stiff kind; the nettle prefers that of a dry, loamy description; the common rush appears only in a wet, cold clay soil; the fox-glove [*digitalis purpurea*] affects a sandy and gravelly soil, and the common fern, [*pteris aquilina*] shoots up only from a deep rich soil. It has been suggested, that a catalogue of such plants as grow spontaneously in different situations, might be useful in determining the fertility and properties of soils, in the same way that the period of flowering in different climates denotes the temperature of the season. The growth and healthy aspect of different kinds of forest trees, may be also employed as a pretty good test of the nature of the soil; and the sudden decline and decay of trees, particularly of *fruit* trees, after thriving well for some time, shew that the roots have reached a cold wet sub-soil, which is unfriendly to healthy vegetation. The luxuriant growth of the quick thorn hedge, may be regarded as a certain indication of a good dry soil.

Sect. III. *Of the Classification of Soils.*

The different ingredients which enter into the composition of soil, and the great diversity of the proportions of these ingredients, must obviously give rise to an endless diversity of soils, which have been distinguished by various names, derived sometimes from the supposed predominant material, sometimes from the colour, and sometimes from the texture or coherence of the particles of which they are composed. No attempt which has yet been made to classify soils can be considered as altogether unexceptionable; and perhaps a successful arrangement of this kind, if the nature of the subject admit of it, is only to be accomplished in the progressive improvement of chemical science. But for practical purposes, the classification of soils which has been usually adopted, may be considered as sufficiently precise. Soils have been usually divided into clayey, loamy, chalky, gravelly, sandy, boggy, mossy, or peaty, and heathy or moorish soils.

Clayey soils.—Clay is never found in a state of purity in any soil, so that the name given to a soil of this description must denote the predominance of this ingredient, or the character which it communicates to the soil. And indeed it seems probable, that some soils, which have the property of absorbing and retaining moisture, or of becoming soft and ductile with water, may derive this peculiar character from a smaller proportion of clay than is usually supposed. The clayey soils of some districts, it has been observed, are very fruitful and productive, while those of others are extremely barren and unmanageable. In such cases, a remarkable diversity in the nature or proportions of the constituent parts must exist; and this, it is evident, must direct to different processes, and different applications, for their improvement. But whatever be the constitution of a soil of this nature, it invariably requires greater power, labour, and attention, to bring it into a condition suitable for improvement and the production of good crops than almost any other. Such soils, from their cohesive nature, are usually barren. In wet seasons, the plants which grow in such soils are chilled with excessive moisture, and in dry seasons the tender roots are unable to penetrate the solid ground. The vigorous appearance of the vegetable productions of such a soil, affords a pretty good proof of its fertility; but if they appear languid and stinted in their growth, the soil is cold and barren. The thinner kinds of lands of this description are almost universally poor, and such land is ill adapted for the plough, either in winter or summer; for it cannot resist the alternatives of frost and rain in winter; and if it should be a wet season before seed-time, the prospect of a crop is doubtful; and if ploughed late in spring, the whole depth of the soil is parched during the dry season, and the grain is deprived of nourishment. The end of February, or the beginning of March, is the proper time for ploughing such land.

Improvement of clayey soils.—Many of these soils are capable of essential improvement by the judicious application of manure, and a proper course of management. For the purpose of altering and improving the texture of a clayey soil, limestone or marl is found to be the most efficient substance. Gravel also has been successfully applied in some cases, with the same view; but where these mineral matters cannot be obtained in sufficient quantity, a mixture of dung and sand, and especially of sand from the sea shore, greatly contributes to its fertility. Various other substances, such as composts of chalk and dung, tanners' bark, and other materials, which are fancifully supposed to promote a strong fermentation, have been advantageously employed. Gravel from neighbouring soils, sea or pit coal ashes, rubbish of old buildings, and peat-ashes, are useful ingredients in enriching clayey soils. In cases where a clayey soil contains little or no animal or vegetable matter, and when it also appears to be equally deficient of calcareous matter, a large proportion of dung is the requisite ingredient for its improvement; but where this cannot be procured, a preparation of peat, with a moderate proportion of lime, is the best application. But where such means of improvement are wanting, the growth of pasture grasses should be encouraged and promot-

Of Soils.

ed, for the purpose of supplying it with the necessary quantity of organised substances.

Loamy soils.—The materials of which soils of this description are chiefly composed, are clay, chalk, sand, and gravel, with variable proportions of organised matter. Some of these soils are stiff and compact, while others are loose and porous, and hence they have been distinguished by the names of *heavy*, *stiff*, and *light* loams; and, from the predominance of the ingredients they have been denominated *clayey* loams, *chalky* loams, *sandy* loams, and *gravelly* loams. The first of these is a moderately cohesive soil, in which the argillaceous material predominates. It has less coherence than pure clay, but greater than any other loamy soil. The chalky loam is less cohesive than the former; it is composed of clay, coarse sand, and chalk, and the calcareous ingredient predominates. The sandy loam is composed partly of coarse and partly of fine sand, and is less cohesive than the two former. Gravelly loams, as the name imports, contain a larger mixture of coarse sand or gravel, and, when the soil happens to be shallow, this variety, as well as the two last, come under the denomination of *hungry* soils. Some of the light loams have been distinguished by the name of *sharp lands*.

Improvement of loamy soils.—Soils of this description are improved with greater facility, and at less expense, than those of a clayey nature. Those of the heavier and more adhesive kinds, require a compost of lime and dung, or lime in combination with animal matters, as ground bones and blood. Loams near the banks of rivers, or the sea-coast, are usually so fertile as to demand less aid from manure; but, in general, manure proper for such soils must be varied according to the proportions of the ingredients they contain, or the different degrees of their fertility. Loamy soils, when properly managed, are capable of yielding almost every kind of crop, and not only those of the grain and root kind, but also pulse, hemp, and flax.

Chalky soils.—Extensive tracts in some of the southern districts of England, are occupied with chalky soils; and here, as well as in others, a considerable diversity prevails, both with regard to the thickness and constituent parts of the soil itself, and the nature of the subsoil. When the clayey and loamy ingredients are predominant, the heavier kind of chalky soils are formed; but sand or gravel abounding, constitutes the lighter chalky soils. When the quantity of earthy matter is small, and not reduced to the state of perfect mould, the soil is poor and thin; but where the thickness of the superficial layer is considerable, and the organized matter is almost entirely decomposed, the soil is rich and heavy. When the subsoil is compact, and blended with siliceous matter, it is less favourable to the fertility of the soil than when it is of an open or brittle nature.

Improvement of chalky soils.—Vegetable matters, deposited and accumulated in wet or swampy situations, are beneficially applied to the thinner or lighter calcareous soils. The addition of sandy and clayey loams to those of a heavier description, alters, and greatly improves their texture, and the same good effects are obtained from the use of composts of vegetable and animal matters, farm-yard manure, and ashes, soot, and malt dust. The proper season for breaking up such land should be particularly attended to; for if the operation be deferred till dry weather, the soil becomes so hard as to be almost unmanageable, till it be softened by the rain.

Of Soils.

Gravelly soils.—Soils which come under this denomination are very different, according to the nature of the earthy matters which enter into their composition, and the size of the stony particles from which they derive their characteristic property. These stony particles vary in magnitude, from the size of the smallest pea to that of the egg of a pullet. When they are larger, the soil is denominated a *rocky* soil. Beds of gravel are chiefly composed of siliceous or calcareous matters, while the rocky and stony substances are of different qualities. In some cases, the gravelly mixture has been found to approach nearly to the surface, while, in others, it is at a considerable distance below it. Where the stratum of gravel is near the top, a full crop of broom covers the ground, when the land is under grass; and a crop of sheep sorrel is equally abundant when it is in tillage. Sometimes springs are observed to burst out near the surface, at other times they can only be discovered at a great depth. A similar diversity prevails in the subsoil, consisting sometimes of rocky masses, and sometimes of clay, of rocky gravel, or sand. From the porous nature of gravelly soils, they readily absorb moisture, and with the same facility part with it, from which it happens that, in dry seasons, they exhibit a parched and withered aspect.

Improvements of gravelly soils.—The materials to be added to gravelly soils of a calcareous nature, to increase their fertility, are clay and clay loam. A mixture of carbonate of lime or chalk, with clay, has also appeared beneficial to such soils. Chalk is particularly recommended for those kinds of gravelly soil which contiguity to springs is apt to render moist in the winter season. The application of chalk is stated as having a powerful effect, not only in counteracting the redundant moisture, but in correcting the tendency to become parched in the summer, an evil to which most gravels are in some degree liable, and which is often so injurious to the crop.

The defect of vegetable and animal matters is to be supplied by means of dung from the farm-yard, in its reduced state; and much benefit is derived from other animal matters, prepared in the form of composts, with good loamy mould, ashes, clay, depositions of rivers and ponds, with other substances of a similar nature. The proper alternation of green vegetable, and other crops, also contributes greatly to improve the fertility of such lands.

Sandy soils.—The varieties of soils of this description depend on the nature of the rocks from which they derive their origin, and the different proportions of other matters of which they are composed. In some districts, soils of this kind are found, varying from the lightest species of loam to the naked sand, composed almost entirely of small siliceous particles; but the proportion of other earthy matters renders them more or less favourable to vegetation. When that proportion is nearly equal to the sand, the mixture affords the heavier kinds of sandy soils; but when they are in smaller quantities, a light sandy soil

Of Soils.

is formed; and when composed entirely of siliceous particles, it constitutes a loose blowing sand, usually of a white or brownish appearance. The variety of texture and composition in such soils, is closely connected with the power of absorbing and retaining heat and moisture.

Improvement of sandy soils.—The want of coherence is one of the chief defects of sandy soils. This defect is supplied by the application of clay or loamy substances; and the other great defect, the want of animal and vegetable matters, is to be supplied by the free use of dung. For this purpose, clay and loam, either alone or in the form of compost, with animal and vegetable manure, or good mould, or peaty earth, either alone or in combination with other substances, may be successfully employed. It is scarcely necessary to add, that the proportion of ingredients to be applied, must correspond with the quality of the soil to be improved. The treading of sheep, folded upon sandy soils, has been found to increase their tenacity and firmness, while the dung and urine of these animals contribute much to their fertility. The author of the Agricultural Report of East Lothian, observes, that "considerable tracts of this soil, formerly of little value, have been brought under the plough, and made to produce excellent crops of turnips, clover, barley, rye, &c.; but the most valuable improvement on this description of soil has been made by laying it into grass, and treating it with top-dressings of different kinds of soils, which, when liberally applied, have, in not a few instances, changed the appearance, and so much altered its nature, as to render it capable of bearing a succession of valuable crops of grain."

Boggy soils.—Soils of this description chiefly exist in low confined situations, are frequently met with in Ireland, and sometimes in low meadows in the vicinity of large ponds or lakes in this country. The formation of these soils depends on the gradual decay and deposition of the more luxuriant aquatic vegetables, and the stagnation of water, by which their roots are destroyed and reduced to the state of earth; the state of putrefaction and decay to which the plants have advanced, and the nature of the earthy materials with which they are mixed, diversifying their appearance with regard both to colour and texture. Sometimes the colour is of a lightish brown, when the fibrous and ligneous matters have been but slightly changed; but when the process of decomposition has proceeded farther, they become of a dark or black colour.

Improvement of boggy soils.—Draining is the first obvious practice in the improvement of such soils, while the application of chalk, gravel, sand, or shell-marl, serves to bind and correct their texture. Paring and burning has been sometimes employed with advantage; planting such vegetables as have spreading roots, counteracts the excessive porousness of boggy soils; and flooding, where water is within reach, has been successfully practised. Soils of this description have been sometimes converted into meadow pasture, with the best effects, when other means of improvement had failed.

Mossy and peaty soils.—Considerable tracts of country in the northern parts of Britain, and in many parts of Ireland, are covered with this kind of soil, which varies in its qualities, according to the diversity and proportion of the ingredients which enter into its composition. When the vegetable material is in small proportion, the lighter kinds of peaty soil are formed; but when the peaty matter predominates, the deep and heavy mossy soil appears. The peaty matter is of various depths, and of various density, arising, probably, from original difference in the vegetable substances from which it was formed, or from different stages of its decomposition.

In many of the deep mossy districts, the subsoil is of a clayey nature, over which the mossy matter is deposited in a kind of stratified order. The first layer is usually about a foot thick, and has the appearance of a rich brown earth, from a mixture of the loamy or clayey substance with the vegetable earth; the succeeding layer is of a dark colour, considerable thickness, and of various degrees of density. The uppermost stratum is of a pale colour, and a spongy texture, arising from a less perfect state of decay.

Improvement of mossy soils.—To render mossy soils productive, the first step is, to remove the redundant water by proper draining. But certain precautions are necessary in conducting this operation; for, when the whole of the moisture is suddenly withdrawn, the surface becomes so dry and hard as to resist the action of the spade or plough. The draining, then, must proceed gradually, and as much of what may be called the natural moisture should remain in the soil, till the necessary operations of tillage are completed, and the first crops have so far advanced as to cover the ground, and protect the surface from excessive evaporation.

When moss rests on a good subsoil, and when water can be procured in such quantity, a method of improving such soils by floating away great part of the mossy substance, has been successfully pursued. By this method, a great extent of most valuable land in Blair-Drummond moss, in Perthshire, in Scotland, has been completely reclaimed within the last 50 years, and is now covered with all kinds of luxuriant crops.

But when the moss is shallow, and the inferior soil of indifferent quality, after draining and forming the surface into ridges, in such a way as to allow the stagnant water to pass off, the next object is the application of such substances as shall promote the entire decomposition of the vegetable matter, and improve the texture of the soil. With this view, quick-lime, soapers waste, chalk, marl, shell sand, different gravelly substances, sand, and coarse earthy matters, may be advantageously employed. When the quantity of vegetable matter is abundant, and of coarse quality, paring and burning may be an essential improvement; but the application of earthy rubbish produces powerful effects on such a soil. The species of crop raised on mossy soil, have no small share in promoting their fertility. Plants, as the turnip and potatoe, which have large leaves or branching stems, cover the surface, preclude the action of the air, and retain the necessary moisture.

Heathy or moory soils.—This kind of soil is of great extent in different parts of the kingdom; and although, in many of its characters, it is very difforent from the preceding, it resembles it in some of its properties. Two kinds of heathy soil have been described. The first is of a black, soft, porous nature, is very absorbent, and the stones which are distributed on the surface have the remarkable appearance of being bleached; the process of disintegration seems to be completely interrupted; for they are altogether destitute of the incipient vegetation which is rarely absent from stones of a different quality, or in a different situation. The most prominent quality in this kind of soil is its unaccountable sterility. No methods of improvement yet attempted have been followed with success, or have brought any adequate returns for the requisite labour and expence.

The second kind of moory soil presents very different characters. The vegetable remains are in a dry state, intermixed with earth, have many of the properties common to all vegetables, and, under proper management, may be converted into fertile soil. The stones on this kind of moor land have not the bleached appearance, but resemble those which are found in the best soils.

Improvement of heathy soils.—The proportion of vegetable matter, and the depth of soils of this kind, serve to direct to the proper means of improvement. When the remains of heath and of other coarse plants are abundant, and the thickness of the bed is considerable, paring and burning may prove the most effectual process in the operation, in reclaiming them; but when the soil is shallow, and the quantity of vegetable matter deficient, other means must be adopted. In many cases, quicklime, which destroys the coarse herbage, and promotes the growth of pasture grasses of a superior quality, is highly beneficial. Marl of different kinds may be also applied, with much advantage, to soils of this description. Such soils are also susceptible of great improvement by the application of animal and vegetable matters, as dung and the mud of ponds, in the form of earthy composts, as well as by a judicious alternation of grain and green crops.

Chap. IV. Of Manures.

When land, however rich and fertile it may be, is continued under a course of cropping, without receiving any addition to the soil, it soon becomes less productive, or, in common language, it is exhausted. The value of the produce is at last so greatly diminished, as to afford no compensation for the expence of tillage; and no management can increase it, or restore the fertility of the soil, without the application of certain matters, which are well known by the name of *manures*. Manures, then, are substances artificially mixed with the soil, for the purpose of increasing its diminished fertility. The effects of manure may refer either to the improvement of the texture of the soil, or to the supply of those matters which constitute the food of plants, to the correction of noxious ingredients in the soil, or to the increase of the usefulness of such as already exist in it.

The substances which have been usually employed for the purpose of manures, are either of a mineral, vegetable, or animal nature, certain saline substances, and compounds, formed of two or more of these substances. They have been divided into earthy, putrescent, or putrescible, saline, and compost manures. The nature and properties, with the preparation and application of these substances, shall be treated of in the four following sections.

Sect. I. *Of Earthy Manures.*

The earthy matters which have been employed as manures, are, calcareous earth, clay, sand, loam, &c.

1. *Calcareous earth.*

Calcareous earth, either united with other substances, or in an uncombined state, is extensively applied to the improvement of land; and in many cases it is one of the most essential ingredients that can be mixed with the soil. It is used in the state of quicklime, or lime, combined with an acid in the form of carbonate, as limestone, chalk, sea-shells, or that of sulphate or gypsum, and blended with other earthy bodies, as in the different varieties of marl.

Lime.

Lime, as it exists in nature, is always in a state of combination, and by far the most common compound is that of carbonate, in which it is united with carbonic acid, under the well-known forms of limespar, marble, limestone; and in lime-spar, and the purer kind of marbles, the carbonate of lime is almost the sole constituent; but in limestone, the mineral from which lime, for the purposes of agriculture and of cement, is derived, is rarely free from a certain portion of clay and siliceous earth, and sometimes it is contaminated with metallic matters.

When limestone is subjected to strong heat, the carbonic acid with which it is combined is driven off, and it is found to have lost a portion of its weight equal to the elastic fluid which has escaped. When the burnt mass is exposed to a moist air, it absorbs water, swells, and falls down into a powder, which is lime, or quick-lime, more or less pure according to the purity of the limestone. But the limestone, when it is reduced to this powdery state by calcination and the absorption of moisture, has acquired new properties. Limestone, in the state of the finest powder, has no perceptible effect on animal or vegetable matters, but quick lime is acrid and corrosive; and this is the foundation of the distinctive characters of lime in the two states, under the denomination of mild and caustic. By the calcination of limestone, the object of which is to separate the carbonic acid, it is deprived of from seven to eight parts out of twenty of its weight, or from 35 to 40 per cent., and when it is very pure the loss of weight is nearly equal to one-half the weight of the stone; but it is obvious that this loss of weight must vary according to the variable proportions of other earths. When water is gradually added to fresh burnt lime, great heat is produced, and the water enters into combination with the earth, which is called the slaking of lime, in which process it combines with about one-third of its weight of water.

Analysis of limestone.—As common limestones have

Manures.

very different degrees of purity, it is obviously of great importance to ascertain the quantity of calcareous matter which enters into their composition. In general, it may be observed, that the greater the loss of weight which they sustain in burning, the greater is the proportion of pure lime. A pretty accurate comparative estimate may be made of the quantity of calcareous matter in any limestone, by observing, first, how much diluted nitric or muriatic acid is required for the complete saturation of a determinate portion of a specimen of the purest limestone; and, secondly, by ascertaining how much of the limestone to be examined will saturate an equal portion of the same acid. If, in the latter case, a double quantity is found necessary, then the stone contains only half the quantity of the calcareous earth which is in combination with the purer specimen. The comparative purity of different limestones may be also estimated, by dissolving a small portion of the stone to be examined in muriatic acid, and observing the quantity of undissolved matter, if any remain, and the smaller the proportion of residue which is not acted upon by the acid the greater is the proportion of calcareous matter contained in the limestone. A simpler and more obvious test is generally had recourse to by practical agriculturists, which consists in the comparative measurement of the burnt limestone in the unslaked state, and of the lime in the state of powder after it is slaked, the latter being three times the quantity of the former, when the limestone is of a good quality.

But a more accurate method of analysis may be pursued, according to the following process: Dissolve a determinate portion of the limestone in twice its weight of muriatic acid, diluted with double its bulk of water; filter the liquid, and add a solution of carbonate of potash till the effervescence ceases, and till the taste and smell indicate the excess of the latter salt. The precipitate is carbonate of lime, which, being collected on the filter, is to be dried at a heat below that of redness. Boil the remaining fluid for fifteen minutes; and if any magnesia exist in solution, it falls down in the form of carbonate, when, by similar treatment, its quantity may be ascertained. If any alumina should be dissolved by the acid, it may be detected in the precipitate with the carbonate of lime, by boiling for a few minutes with soap-ley, which dissolves alumina, but has no action upon carbonate of lime.

As carbonate of lime contains a determinate proportion of carbonic acid, which amounts to about 43 per cent., when the amount of this elastic fluid, obtained during the solution of its calcareous matter in an acid, is known, the quantity of carbonate of lime is easily ascertained. If two parts of the acid, and one part of the mineral, be weighed in two separate bottles, and if they are slowly mixed together till all effervescence ceases, the difference between their weight before and after the experiment indicates the quantity of carbonic acid lost; and for every four grains and a quarter of loss of weight, ten grains of carbonate of lime are to be estimated.

The bulk of carbonic acid given out by a determinate portion of carbonate of lime, is estimated, by an ingenious apparatus, described by Sir Humphry Davy. The limestone to be examined is introduced into a bottle with two orifices; a bottle for containing the acid, and furnished with a stop-cock, is fitted by grinding to the upper orifice. From the orifice in the side proceeds a glass tube, to the end of which a flaccid bladder is fixed, which is introduced into another vessel filled with water, and to the side of this vessel is fixed a spout. When the acid comes in contact with the limestone, the carbonic acid, which is driven off, is received into the bladder, and displaces a quantity of water equal to its own bulk. This water is received into a graduated measure, that the amount may be ascertained; and for every ounce measure, two grains of carbonate of lime are to be estimated.

Magnesian limestone.—The constituent parts and action of magnesian limestone on the soil, are very different from those of the common limestone. This variety is very abundant in some of the northern and midland districts of England; and, from its active nature, it is distinguished by the name of *hot lime.* The colour of this stone is usually pale yellow or brown. It effervesces very slowly in acids, and communicates a milky appearance to diluted nitric acid. The component parts of this limestone are from 20 to 22 of magnesia; from 29 to 31 of lime; about 47 of carbonic acid; and a small portion of clay and oxide of iron.

Burning lime.—In the preparation of lime by calcination or burning, a good deal of attention is necessary to the nature of the stone employed. And here the aid of chemistry, in ascertaining its constituent parts, might be highly beneficial. It is stated by Sir Humphry Davy, that one bushel of coal is, in general, sufficient to make four or five bushels of lime; but the proportion of the fuel and the product must vary according to the nature of both. It appears, that the magnesian limestone requires less fuel than common limestone. In burning the less pure limestones, or those which contain a large proportion of alumina or sand, the management of the fire must be particularly atteuded to; for a heat of too great intensity produces a vitrified mass. Good lime is obtained at a low red heat; but if the fire be raised to a white heat, the mineral melts into a glass. The purity of common limestones, it has been already noticed, may be estimated by their loss of weight in burning; for the quantity of calcareous matter corresponds with the loss of weight. If the limestone is not apt to *run*, or become vitrified in burning—if the calcined stone or shells be extremely light, and require a great deal of water to slake them fully—if it swell much in slaking, and if the lime be light, fine to the touch, and of a pure white—it may be safely concluded that the lime is of a good quality. The magnesian limestones, when subjected to calcination, lose more than half their weight.

Soils requiring lime.—The soils which are essentially improved by the use of lime, are such as are denominated cold, stiff soils, as strong clays and deep loams, or such as are combined with a large proportion of vegetable matter, but contain no portion of calcareous earth in their composition. Lime may be regarded as of singular advantage in all soils and situations, excepting on thin loams, sandy soils, or those which are already replete with that earth. To ascertain whether any calcareous matter exist in a soil, recourse may be had to a very simple experiment, proposed by Mr Young. Let a small quantity of the soil to be examined be collected by going over the field, and taking up from different parts of it a few grains with the finger and thumb. The whole being put together, and introduced into a wine-glass, add first a little water, and after stirring it, and allowing any air that may adhere to the particles of earth to escape, pour on a little muriatic acid; if no effervescence take place, the soil may be accounted destitute of lime.

Application of lime.—Considerable diversity of opinion prevails with regard to the time and circumstances of the soil in which lime should be applied. In whatever way lime operates, whether by its mechanical effects on the soil, altering and improving its consistence and texture, or by certain chemical changes on the organized matter in the soil, or on its vegetable productions, by which they are rendered more healthy and vigorous, one of the first objects in its application is its equal and uniform distribution, that it may be brought into contact with every part of the soil on which it is to operate. But with all our improvements in rural economy, in many parts of the country, at the present day, no work is performed in a more slovenly and imperfect manner.

To insure this equal distribution, the lime must be in the form of powder, and in as dry a state as possible. For this purpose the calcined stones should be laid together in considerable heaps; and as they absorb moisture from the earth or atmosphere, they gradually swell and fall to pieces. But in case this process of spontaneous slaking, as it may be called, should not go on with sufficient rapidity, it may be promoted by throwing water on the heap. Too much water must be avoided; or, in case of heavy rains before the lime is spread out on the field, it has been very properly recommended to cover up the heaps to prevent it from running together into clots, or forming a kind of mortar. Might it not be suggested as a useful and convenient method, for the equal application of lime, to mix it carefully with a quantity of dry earth; and if earth of a different kind from the soil to be improved could be easily obtained, the increased value of the compost, in contributing to the fertility of the land, would undoubtedly be an ample compensation for the additional labour? But perhaps the smaller quantity of lime which might be necessary in consequence of its more equal distribution, might, in some measure, counterbalance the extraordinary expense.

When lime is to be applied to land in fallow, a dry season should be selected, when the surface is in proper condition for its reception; and as much inconvenience and some injury arise to men and horses when this work is performed in windy weather, which also renders it difficult to spread the lime equally, a day should be preferred when a moderate breeze prevails, which, in some degree, assists in its uniform distribution. All the operations of tillage, after the application of lime, should be conducted when the soil is perfectly dry; and, to prevent the horses' feet from being corroded, they should not come in contact with water till the lime is brushed off; but in case of accidents, from its acrid effects, to men or horses, washing the part affected with sour-milk or whey is an effectual remedy; and the longer the milk or whey is kept the better it answers the purpose. Vinegar or stale urine is recommended as a substitute.

As lime cannot produce its effects without being intimately mixed with the soil, the time and condition of the land when this object can be fully attained, require attentive consideration. But on this point great diversity of opinion prevails. The most general rule that can be given for the application of lime, is, that the soil which is to receive it should be as dry as it can be made, and in as complete a state of division as can be accomplished by the operations of tillage. The dry season of the year, it is obvious, is the most suitable for the strict observation of this rule; for then the soil is in the best condition, and the operations alluded to are best performed. The spring, summer, and autumn months, when the weather is favourable, are the most proper for this kind of work.

Another general rule to be observed in the use of lime, is, that it should be mixed with that part of the soil which is nearest to the surface. The most proper time for its application, then, seems to be at the conclusion of the operations for fallowing, when all that is necessary, after it is equally spread, is a slight harrowing, or, if ploughing be required, it should be performed with a very shallow furrow, that the lime may not be buried too deep. With the same view of retaining this manure near the surface, lime is advantageously applied to lands destined for turnips, wheat, and other crops, immediately before the insertion of the seed, so that a moderate harrowing is the only operation that remains to be performed. Repeated ploughings are recommended by some, for the purpose of mixing the lime laid on fallow intimately with the soil; but there is some risk of part of it being carried beyond the reach of vegetation; and the same effect seems to follow when lime is laid on grass lands which are to be broken up; for the lime is carried to the bottom of the furrow; and its beneficial effects, if they are ever so powerful, are not experienced till it be again turned up by the plough in the operations for succeeding crops.

When lime is to be employed as a top-dressing for pasture-lands, it should be applied early in the spring or autumn, rather than in summer or winter; because in a dry summer the grass is apt to be burnt up, and in winter the effects of the lime are supposed to be diminished by frost. The same rule is perhaps equally applicable to the use of lime on moorland pastures.

Application a second time injurious.—When the effects of lime have disappeared, it might at first sight be expected, that a repetition of the dose would be equally beneficial, in restoring the exhausted fertility of the soil, with the first application. But, from very general experience, it appears, that unmixed lime added a second time to the same soil, even after an interval of many years, is injurious to vegetation; and hence it seems to be an established rule, in all cases where the use of lime seems to be indicated, to apply it in smaller proportion, and always in the form of compost with dung. This practice is highly advantageous.

Quantity of lime.—No precise rules can be given for the quantity of this manure which should be applied to any particular soil; it seems indeed to be more regulated by accident, or by vague opinion, than by any fixed principle. It appears to be a pretty general notion, that light, sandy, or loamy soils, require a smaller proportion than stiff clays; but in no case is the determinate quantity accurately ascertained. From this unsettled practice, it may be expected that the quantity of lime used as manure is extremely variable, and perhaps often regulated by its abundance in the district, or the expense at which it can be procured. The quantity of lime employed in different parts of the kingdom, and on different soils, varies from one hundred to five and six hundred, and even to a thousand bushels, for the English statute acre. But from an hundred to an hundred and fifty bushels are stated to be the average quantity commonly employed throughout the kingdom. In the Peak of Derbyshire, from three hundred and sixty to one thousand bushels are applied to the heath and moorlands, by which they are converted into excellent pastures. But, as it has been justly observed by Dr Coventry, that an excessive quantity, or an over-dose of lime, does not appear to have been in any case injurious, yet it is not beneficial, and is therefore to be considered as a useless expenditure.

The beneficial effects of a small quantity of lime in the improvement of hilly or outfield land, are fully illustrated in the practice of the late Mr Dawson, one of the most intelligent and judicious farmers in the south of Scotland. A few years after 1754, Mr Dawson wished to lime some outfield land in fallow, previously to laying it down in pasture. A sufficient quantity of lime, which was supposed necessary for the whole, could not be obtained in proper time; but observing the effects of fine loam on the surface of similar soil, he was induced to try the effects of a small quantity on the surface of the fallow, instead of a larger quantity ploughed down. Twenty acres were well harrowed in the autumn; after which, about 56 Winchester bushels of unslaked lime were, after being slaked, carefully spread, and immediately well harrowed in; and in three or four days afterwards the land was again harrowed, to mix completely with the soil those pieces of the lime which were slowly reduced to powder. In this state the land remained during the winter. In the spring it was sown with oats, with white and red clover, and rye-grass seeds, and well harrowed, without ploughing. The crop of oats was abundant; the grass grew luxuriantly, and continued to be a fine pasture, until it was broken up some years afterwards for a corn crop.

A similar experiment made twelve years afterwards by the same agriculturist on another hilly farm, affords a farther illustration of this excellent practice. Many parts of the land were too steep and elevated for tillage, although the soil had a tolerable depth of earthy mould. The lands were greatly exhausted by cropping, and were full of couch grass. They were fallowed; received the same quantity of lime; were harrowed, and sown with oats and grass-seeds in the spring: As in the former case, the oats were a full crop, and the herbage plants were abundant. Some of these fields were more than thirty years in pasture, and were still clothed with white clover and other excellent grasses, without the appearance of bent or fog. But the comparative view which is given of this experiment, merits particular notice. More than three times the quantity of lime was laid upon adjoining fields of a similar soil; but, being more calculated for tillage, the lime was ploughed in. Oats and grass seeds were also sown on these fields, which, during the first year, were covered with a fine pasture; but afterwards the bent spread so rapidly, that, in the course of three years, it was more abundant than the finer grasses.

The following practical inferences, drawn from Mr Dawson's experience in the use of lime and dung, are highly important.

1. That animal dung, dropt upon coarse benty pastures, produces scarcely any improvement; and that when sheep or cattle are folded, as they are confined to a small space, their dung, after a few years, has no effect, whether the land be in pasture or tillage.

2. That when land of this description is well fallowed and dunged, but not limed, the produce of the grain crop, and of grass for two or three years, is improved, but afterwards the effects entirely disappear.

3. That when this land is limed, if the lime be kept on the surface, or well mixed with it, and then laid down to pasture, the finer grasses spring up and thrive, even in high and exposed situations, to the exclusion of coarse herbage, for many years. In one of the experiments mentioned above, the pasture had continued of a good quality for more than thirty years.

4. That when a large quantity of lime is applied to such land, and ploughed down deep, the same effects do not follow, either with regard to the permanency of good pasture, or the fertility of the soil under tillage. On the contrary, unless the surface be well mixed with lime, the coarse grasses in a few years cover the soil, and the land is not enriched for future tillage by pasturing with cattle.*

Magnesian lime.—This variety of lime has been long used in those parts of England where it is abundant; but it was found, from general experience, that when it was employed in the same quantity with common lime, it injured the crops for many years. The cause of this remarkable diversity in the effects of lime were not discovered till 1800, when Mr Tennant examined this species of limestone, and found that it contained magnesian earth, which, when employed in large quantities in its caustic state, is hurtful to vegetation. From this circumstance it has been called *hot lime*. The quantity employed with good effect is from 25 to 30 bushels for each acre; and when the land is rich, and contains a large proportion of vegetable matter, it may be employed in

* Farmers' Magazine, vol. xiii.

larger quantities. But when the magnesia is in its mild state, or in that of carbonate, it seems to be an useful ingredient in the constitution of soils. The soil of the Lizard Downs, in Cornwall, which bear a short and green grass, which is an excellent pasture for sheep, and, when under tillage, produces the best corn in the country, contains mild magnesian earth.

Effects and operation of lime.—The effects of lime in improving the texture of the soil, and in contributing to its fertility, are so well known as scarcely to require any elucidation. It has been stated, indeed, that the improvement of a stiff soil by the use of lime, is such, that the saving of labour is almost a full compensation for the expence. The effects of lime are observed, not only in increasing the quantity of the produce, but also in improving its quality. Those who are accustomed to deal in wheat, entertain the opinion, that the husk or skin is thinner when it grows on land which has been limed, that is, that it yields a larger proportion of flour, and of better quality. It seems also to be a well established fact, that no kind of pease succeeds well, even on the richest and best manured soils, without the use of lime. The pease vegetate, and for sometime grow vigorously, but before they begin to ripen they become blighted, usually die away entirely before the pod is formed, and but rarely produce a few half formed peas; but when lime has been applied to the soil, an abundant crop of full formed pease is obtained. The same fact has been noticed in the southern counties of Scotland, particularly in the Galawater district. It has been observed, that the soil, however richly manured, without lime, throws up a profusion of straw in the corn and pease crops, but the grain is extremely deficient. This is completely remedied by the use of lime. The luxuriance of the straw is checked, and the seed, whether grain or pulse, becomes full and plump. In the same district, observation has established another important fact. It appears that one-third, and, in some cases, only one-fifth of the quantity of lime employed in other parts of the country, produce as powerful effects as the larger proportion. But perhaps it is more equally spread, or otherwise more carefully managed, in consequence of the great expense attending a long land carriage.

But although the effects of lime be obvious and certain, its mode of operation is yet a secret. Numerous speculations have been indulged on this subject; but till chemistry and physiology shall have made farther advances in unfolding the changes which take place in the soil, and in developing some of the secrets of the vegetative process, we must consider the whole as doubtful conjecture.

In the following remarks by Sir Humphry Davy, an attempt is made to explain the operation of lime in fertilizing the soil: "When lime, whether freshly burnt or slaked, is mixed with any moist vegetable matter, there is a strong action between the lime and the vegetable matter, and they form a kind of compost together, of which a part is usually soluble in water. By this kind of operation, lime renders matter, which was before inert, nutritive; and as charcoal and oxygen abound in all vegetable matters, it becomes at the same time converted into carbonate of lime.

"Mild lime, powdered limestone, marls, and chalk, have no action of this kind upon vegetable matter; by their action they prevent the too rapid decomposition of substances already dissolved, but they have no tendency to form soluble matters. It is obvious, from these circumstances, that the operation of quick lime and marl, or chalk, depends upon principles altogether different. Quick lime, in being applied to land, tends to bring any hard vegetable matter that it contains into a state of more rapid decomposition and solution, so as to render it a proper food for plants. Chalk and marl, or carbonate of lime, will only improve the texture of the soil, or its relation to absorption; it acts merely as one of its earthy ingredients; quick lime, when it becomes mild, operates in the same manner as chalk, but, in the act of becoming mild, it prepares soluble out of insoluble matter. It is upon this circumstance that the operation of lime, in the preparation for wheat crops, depends, and its efficacy in fertilizing peats, and in bringing into a state of cultivation all soils abounding in hard roots, or dry fibres, or inert vegetable matter.*

Chalk.

Chalk is also a carbonate of lime, usually in a state of greater purity than common limestone. The proportion of clay, or siliceous earth, with which it is combined, is in general very small. Chalk, from the slight degree of coherence among its particles, is light, porous, and easily reduced to powder. These properties render it valuable as a manure in the southern counties of England, where it abounds. Its effects must be in a great measure similar to those of the other calcareous matters in the same state of combination. It answers well for deep soils, and thin poor clays; but when employed on light soils, the usual mode of application is in the form of compost with dung, either as fallow for wheat, or as a top-dressing on grass, from which the moss, rushes, and other coarse plants, where previous draining has been performed, are soon banished.

Mode of application.—Chalk is sometimes burned, and then it is in the state of quick lime; but when it is employed unburnt, it should be reduced to small pieces, an operation of no great difficulty when it is dug from the pit about the end of autumn, and immediately afterwards laid on the land. From its porous nature it readily absorbs moisture, which freezing in the winter, causes the mass to swell and fall to pieces. It has been stated, that chalk applied to the soil, in excessive proportion, may prove injurious; but the remark surely proceeds from inaccurate observation, for the effects of chalk are not more powerful than those of lime; and it has been mentioned, from good authority, that an overdose of the latter is not prejudicial.

Sea Shells.

Shells, or the covering of testaceous animals, are composed of carbonate of lime and a portion of ani-

* Agricultural Chemistry, p. 277.

mal matter, ingredients which must render them highly beneficial as a manure. Extensive beds of broken sea shells are found on the shores of the ocean, in different parts of the kingdom, and are valuable sources of excellent manure to all soils which require lime in its mild state. When shells are burnt, their effects are similar to quick lime. Oyster and mussel shells in their fresh state are frequently spread on land, and are found to produce very beneficial effects. Might it not be an improvement in their mode of application, to have them bruised or pounded, by which both the calcareous and animal ingredients in their composition would be sooner incorporated with the soil?

Marl.

Marl is of great use as a manure where limestone and fuel are scarce or high priced. According to its composition or consistence, it is distinguished by different names, as *clay-marl, stone-marl, slate-marl, shell-marl.*

Clay-marl has some resemblance to clay, of which it often contains a considerable proportion, and it readily absorbs water. Stone-marl derives its name from its hardness, and is less soluble in water than the preceding. Slate-marl is of a laminar structure, is of an intermediate consistence between the two former varieties, and is not of a very absorbent quality. Shell-marl is distinguished by the shells in different stages of disintegration with which it is intermixed, and the slighter cohesion of its parts. This kind of marl is found deposited in places which have been covered with water, and the shells appear to belong to fresh water animals.

The value of marl as a manure depends chiefly on the proportion of calcareous matter with which it is combined. This may be discovered by the process already described in the analysis of limestone, and it is of some importance to ascertain the proportion of its constituent parts, if it be any object to apply a determinate quantity of calcareous matter to the soil to be improved. Some shell-marl has been found to contain 84 per cent. of carbonate of lime, along with some vegetable remains, which renders it peculiarly valuable as a manure. Marl is highly beneficial to certain soils which have lime in their composition naturally, or to which it has been formerly applied, by improving their texture and increasing their thickness, with the addition of the clay and other earths which it contains. It is particularly recommended for grass lands on a thin gravelly soil, in elevated situations where wild or sheeps sorrel abounds. The use of marl in different parts of England is very extensive. In Norfolk and Suffolk the quantity applied to light sandy soil is from 50 to 70 cubical yards the acre; and in the Isle of Man, clay-marl, to the amount of 200 tons for each acre, is employed.

Gypsum.

The use of Gypsum as a manure was first proposed by a German clergyman about the year 1768; since that time it has been extensively, and it is said most advantageously employed in America; but the result of experiments made in this country scarcely warrants the high commendation which it has received. Gypsum is a compound of sulphuric acid and lime. It is better known by the name of plaster of Paris. In some accounts of the remarkable effects of this substance in fertilizing the soil and improving the crop in America, it is stated, that the lands on which this wonderful change is produced are situated at the distance of 80 or 90 miles from the sea; and it is supposed, on the ground of doubtful speculation, that the benefit derived from gypsum as a manure in this country, may be counteracted by the muriatic acid and soda, or common salt in sea air, preventing or retarding its decomposition, or entering into new combinations with its elements, unfavourable to vegetation.

Quantity.—The quantity of gypsum employed in this country is from six to eight bushels per acre; and it has been stated, that it might be beneficial to turnips in dry seasons, to the amount of two bushels only for the acre, when the crop is in drills.

2. *Clay.*

Clay is sometimes advantageously employed in improving the texture and consistence of the soil, and particularly a light kind of sandy soil, which seems to be deficient in that earth. The quantity must be regulated by the nature of the soil to which it is applied, and the time recommended for its application is in the summer and autumn months, or before the winter frosts set in, that it may be broken down and well incorporated with the soil.

Burnt Clay.

The use of burnt clay as a manure has been long known in this country. It was communicated by Lord Cathcart to the Scottish Agricultural Society which existed before the middle of the 18th century. It was employed in the form of compost, in the year 1786, by Mr Arbuthnot, near Peterhead, in Scotland; by Mr Parsons, near Sherborne, in England, in 1794; by Mr Buckley, near Loughborough, in 1796; and it has been lately brought forward in the south of Scotland as a new discovery from Ireland. In the year alluded to, Mr Parsons burnt 1600 loads at least in one week, and not less than 500 loads in a single heap. The expense did not exceed 1½d. per load, and it proved a powerful and permanent manure to a cold retentive clay soil.

Preparation.—The mode of preparing and using this manure is thus described by Lord Cathcart, in a letter dated 1756: "Another piece of improvement which I had from the Earl of Halifax, is that of burning clay. Wherever he meets with heaps of clay in his grounds that have been raised when there has been occasion to make ponds or things of that kind, or when he has occasion to take out clay or mud out of the bottom of ponds, lakes, or ditches, all this he burns in this manner. He takes a long stretch of green ground nearest to the heaps. This stripe of ground he pares. The turfs are set up to dry; which being gathered into heaps at a good distance one from another, serve for kindling of the clay and mud. The driest of the clay is first laid on the kindling, and when that is well in fire, men continue to add of the clay and mud, even wet as they are out of the ponds or ditches, to the kindled heaps.

till the quantity is burned. In September or October the ashes are led out, at the rate of forty tons to an acre of the poorest grass, and spread immediately, so as to have the winter rains wash them in. My Lord reckons the charge of managing one acre in this fashion costs him 15s. Last year, that acre that formerly was not worth half-a-crown, produced him at the rate of two loads and a-half of hay, which was worth 50s."

The method of burning clay recommended by Mr Parsons, is the following: In the month of March, trenches about 3 feet deep, and 2½ wide, with small ones 18 inches deep, and 14 wide, are formed in the ground to be improved. The turf or surface-soil is first taken off, and equally spread on the ground; but the clay dug out is laid in heaps by the sides of the trenches to dry. The burning commences in May; a few loads of the worst clay are employed as a circular floor or foundation, about a foot thick, to prevent the burning of the surface of the earth under the heap. Three or four large billets of wood are placed upright in the middle of the floor, and leaning against each other; and round these, and over the whole floor, small faggots and brushwood are intermixed, and raised to the height of about 6 feet. Construct a turf wall, at least 3 feet thick, around the heap of wood, and of the same height; three or four openings about 2 feet wide and 2 feet high, and at equal distances, are formed over the bottom of the kiln, by placing three or four sticks across the top of each; throw a quantity of dry turf on the top of the pile, and then kindle the fire with wisps of straw at all the openings, and when the whole pile is on fire shut up the vent holes with turf. Supply the heat with the necessary quantity of turf and clay, which is to be regulated by the smoke emitted. When it is abundant, an addition of clay is required, but when diminished, air must be admitted by forcing a sharp stake through the crown of the heap. When the heap is raised to a convenient height, and the fire has nearly reached the top, rake down the red-hot ashes, and cover them immediately with turf. Before the sod-wall is entirely consumed, it must be replaced by a new one, which confines the heap, and by often pulling it almost flat, prevents its burning too fast. A heap of 60 or 70 feet in circumference, produces 500 loads of ashes. The fire must be carefully watched at all times. Sometimes it burns so fast, that the labour of five or six men is required to supply it with clay. A dry season is the most suitable for this kind of work; but a wet season only retards it a little, for large fires, after two or three days burning, are not extinguished by rain; and the ashes are of a superior quality when the process of calcination is slow and gradual.

The method of burning clay, as it is practised by Mr Craig at Cally, in Galloway, is to form an oblong inclosure of 15 feet by 10, of green turf sods, and raised to the height of three or four feet. In the inside of the inclosure, air pipes, communicating with openings at each corner of the wall, are drawn diagonally, and formed of sods, placed on edge, and of such a width as can be easily covered with another sod. A fire is kindled with wood and dry turf in the speaces between the air-pipes and the outer wall. The whole kiln is then filled with dry turf, and when it is well kindled, the clay is thrown upon it in small quantities. The pipe on the weather side of the kiln only is kept open; the other three being closed up, unless it should be necessary, from a change of wind, to re-open one of them. As the kiln is filled with clay, the outer wall must be gradually raised, and kept at least 18 inches higher than the top of the clay, to protect the fire from the action of the wind. When any breach is made in the outer wall by burning, it must be immediately repaired. The wall may be raised to any convenient height for throwing on the clay, and the kiln may be increased to any size by forming a new wall on the outside. Some of the kilns constructed by Mr Craig, afforded more than 100 loads of ashes. The proper management of a kiln of this description, depends on the exclusion of the air by the outer walls, and the attention that is given to have the top always lightly but completely covered with clay. The masses of clay are of various sizes, some as large as a man's head; and it burns better by being dried for a day or two before it be thrown on the kiln.

Effects and quantity used.—In a comparative experiment, by Mr Craig, of raising turnips by means of stable-dung and clay-ashes, the crop in the ground manured with the ashes sprung earlier, was more vigorous, and the turnips were double the size. In another experiment by Mr Wallace, in the same district, a very abundant crop of turnips was also obtained. The quantity of ashes employed was from 30 to 50 single cart loads for the acre. Mr Parsons applied from 50 to 60 bushels to the acre, on a cold, wet, cohesive soil. Mr Buckley employs about 70 cart-loads to the acre of a stiff soil, on which he thinks its effects in improving the texture, and communicating permanent fertility, are more striking than in any other. The ashes of burnt clay have been also applied as a top-dressing to grass lands, and, according to Lord Cathcart's statement, at the rate of 40 tons to each acre, they produced very powerful effects.

3. *Coal Ashes, &c.*

Ashes, or the product of the combustion of different substances, are found to be useful as manures to certain soils, and chiefly coal and peat ashes.

Coal ashes.—Coal ashes, although rarely employed unmixed with other substances, afford an abundant source of manure in the neighbourhood of populous cities, where coal is the principal fuel. The ingredients of coal ashes vary in their nature and proportions, but they consist chiefly of aluminous and siliceous earth, with a portion of lime, and sometimes of magnesia. These ashes are found to be highly beneficial in correcting the tenacity, and opening the texture of clayey soils. They are in particular use in the neighbourhood of London, for improving those grounds from which brick earth has been dug out. After spreading the ashes on the clay bottom, horse-beans, or some varieties of the garden bean, are planted; and sometimes such lands are laid down with rye grass. Coal ashes answer well, when spread on clover, in March or April, on dry chalky soils; and the quantity employed is from 50 to 60 bushels to the acre.

Peat ashes.—The Berkshire, Wiltshire, and Newbury peat ashes, have been long celebrated in England as an efficient manure. They contain a considerable proportion of gypsum; and the other constituents are calcareous, aluminous, and siliceous earth, a small portion of common and Glauber salt, and sometimes a little oxide of iron, which is indicated by the red colour after calcination. Dutch ashes, the fertilising properties of which have been commended by Sir John Sinclair, in his Account of the Husbandry of the Netherlands, are composed of nearly the same ingredients. In the Netherlands, the Dutch ashes are applied as a manure to clover, which is succeeded by wheat. Nineteen bushels to the English acre afford an abundant crop of both. The English peat ashes are employed as a top-dressing for cultivated grasses, particularly sainfoin and clover, in the quantity of from 30 to 40 bushels to the acre.

4. *Sand, Loam, &c.*

Sand has been successfully employed in improving the texture of stiff clay soils. But sand taken up from the mouths of rivers or the shores of the ocean, as it frequently contains a portion of animal and sometimes vegetable matter, may also serve to promote their fertility. The sands of flat shores covered with water only during high spring tides, and which are strongly impregnated with common salt and other saline ingredients, are in some places collected and washed for the extraction of the salt, and afterwards spread on the land as manure. This double manufacture is pretty extensive on the northern shores of the Solway frith; and it seems probable that the latter practice might be advantageously adopted in many places where the situation is favourable. The rubbish of houses, or of old walls built with stone and lime, which is a mixture of sand and lime, with other earthy and sometimes saline matters, constitutes a valuable manure, and in all cases ought to be carefully collected and preserved. Loam, mould, or any mixture of different earths with a portion of organized substances, when added to a bare and sterile soil of a different quality, produces wonderful effects in throwing up a luxuriant race of vegetables.

Sect. II. *Of Putrescent Manures.*

The manures which come under this denomination are obtained from the decay and decomposition of various matters which are furnished by the vegetable and animal kingdoms. Manures of this description are sometimes entirely composed of vegetable matters; sometimes they are chiefly of an animal nature, and often they consist of both. Passing over minute distinctions, we shall consider them under the two heads of vegetable and animal substances.

1. *Vegetable Matters.*

Vegetable substances are applied to the soil for the purpose of contributing to its fertility, either in a fresh and green state, or when they have been subjected to complete decomposition.

Ploughing down green crops.—The practice of turning down crops of succulent green vegetables, as clover, buck-wheat, vetches, beans, turnips, that they may undergo the process of putrefaction on the the soil, and afford nourishment to the growing crop, has been recommended by some writers on agriculture, and is occasionally followed. When this method is to be adopted, a portion of lime, or of peat and lime, or rich vegetable earth, may be spread upon the crop; and after rolling, it may be buried with the plough. This work should be performed in the summer or early part of autumn, that the decay of the vegetable matters may be more speedily promoted. In cases where manure is scarce, this practice may be found useful. But it has been observed by Dr Coventry, that its advantages upon the whole are doubtful; for although it is probable that the quantity of vegetable matter is increased, the expence of the acquisition seems too great; so that facts are yet wanting to prove its economy.

River weeds, &c.—Weeds taken from rivers, ponds, and ditches, and other places, when collected in their most succulent state, and thrown together in heaps that the process of putrefaction may be promoted, afford excellent manure. The heaps should be formed by throwing the materials together as lightly as possible; and sprinkling them with water in a dry season is useful. A small quantity of lime or a portion of good vegetable or peat earth mixed with the heap, enlarges the quantity of manure, and increases its value. When these materials are in a dry state, the process of decomposition is slower; they must be kept moist, and liquid matters from the farm-yard would be found greatly to promote their dissolution. The mud taken from the bottom of rivers, containing a large proportion of vegetable matters, may be frequently employed as useful manures. A portion of lime or rotten dung may be added to the mass, which being frequently turned over, is reduced to a proper state of preparation as a top-dressing for grass lands. But the precaution of spreading manure of this kind thinly, or in small proportion at one application, should be strictly observed.

Malt dust, &c.—The dust of malt, along with the tails or coombs, which are the radicles of the seed protruded by vegetation during the malting process, when they can be got in large quantity, are a useful manure. They are greatly improved, and the quantity increased, by strewing them in the bottom of poultry and pigeon-houses, dung heaps, and necessaries, and also in the bottom of reservoirs into which the urine of cattle and soap-suds are discharged. Malt dust is sown by the hand, from 24 to 32 bushels to the acre, along with barley, and is harrowed in with the seed. It is suitable to most soils.

The husks or ashes which remain after the pressure of rape, cole, and other seeds, to obtain the oil, are also used as manures. They are either reduced to the state of coarse powder, sown by the hand, and harrowed in with the seed, or blended with the materials of the dunghill which has been collected from lean stock, with a great deal of litter. A ton of oil cake, mixed with 20 or 30 tons of dunghill compost, constitutes a rich manure. The proper time for the application of this manure is immediately before showery weather; for the process of decomposition seems to be retarded, till it has absorbed moisture. When in the state of coarse powder, from 30 to 40 bushels are applied to the acre.

Bark, saw-dust, &c.—Bark, after being employed in tanning leather, is used as a manure; and for this purpose it should be collected into heaps of a moderate size, while it retains some moisture; and then by mixing lime with it, and sprinkling with water, the decomposition is promoted. Bark should be reduced nearly to the state of vegetable mould when it is applied to grass lands. It is a prevailing opinion, that this manure is more suitable to stiff and heavy soils than those of a lighter description.

Saw-dust or shavings of wood, when applied to soil, without addition, are slow in their operation; but when they are mixed with animal matters, as blood and garbage, a more rapid decomposition is effected, and substances of this kind may be converted into useful manures.

Sea-weed.—Sea-weed of different species, as *fucus vesiculosus, digitatus, saccharinus,* and some others, is employed both for the purpose of making kelp and manure, on those parts of the sea-coast where it abounds. As a manure, it produces speedy and powerful effects; and those who neglect it, when it is within their reach, are little attentive to their own interest. Sometimes it is spread on the land as soon as it is cut from the rocks where it grows, or collected from the shores as it is washed in by the tides; and in this case it should be ploughed down immediately, for otherwise, in a dry season, its valuable properties are soon dissipated.

Another method of preparing sea-weed for manure is, to cut it in its most luxuriant and succulent state, and to collect it in large heaps, where it remains till it be completely rotten, and in a condition to be spread on the land. But, in this way, it is probable some saline matters are washed away by the rains, and its volatile parts are dissipated in the air. It would, therefore, be a more profitable plan of management, in the preparation of this active manure, especially when the plant is in its fresh state, to form a layer of fresh earth on the spot on which the heap is to be raised, and to mix the whole with a portion of quick-lime, and some other earthy matters; and perhaps it would be a useful precaution to cover the whole, to prevent the effects of the sun and air. By this last method of preparing sea-weed for manure, the quantity is not only increased, but its effects on the soil are more permanent. In the islands of Guernsey and Jersey, sea-weed is much employed as a manure. It is cut in the early part of the spring, and immediately applied to the barley and pasture lands.

2. *Animal Matters.*

The constitution of animal matters is more complicated than that of vegetables; and as the number of their elementary ingredients is greater, so their decomposition or putrefaction, when the vital principle ceases to act, proceeds with greater rapidity by the united agency of their component parts. The diversity of constitution, and of the proportions of the elements of animal matters, exhibit very different degrees in the progress of the putrefactive process, even when the circumstances of moisture, heat, and air are equally favourable. The decomposition of the liquid and soft parts is extremely rapid, while the more solid and harder parts remain for a long time unchanged. These remarks are worthy of attention, in considering the nature, properties, and changes of the animal matters which are employed as manures. The excrementitious matters of animals are in most common use for this purpose; and of these matters, the produce of the live-stock supported on the farm, as it is most abundant, is of greatest importance as a subject of rural economy. When mixed with straw, or other vegetable matter which has been used as litter, it is well known under the name of *farm-yard dung*; in the collection and preparation of which, it has been often asserted, and we fear with too much truth, that no branch of agriculture is so carelessly and slovenly conducted.

Farm-yard dung.—In the present mode of managing this kind of manure, little attention is paid to the situation of the dunghill, the means of promoting the decomposition of the animal and vegetable matters of which it is composed, or the preservation of those ingredients which are dissipated in the air, absorbed by the soil, or washed off by the rains.

Situation for a dunghill.—The proper situation for a dunghill is that where its bottom is nearly on a level, and is composed of such materials as are capable of retaining the moisture. For this purpose, it should be laid with clay, covered with broad flags, or common paving stones. The whole ought to be inclosed with a wall four or five feet high, and with an open space at one extremity, for removing the dung. At the opposite extremity, a reservoir is dug, which is either to be lined with clay, built round with stones, or fitted with a wooden cistern, into which a pump is introduced, for discharging the liquid as it accumulates. The reservoir must be placed at the lower part of the dunghill, and an opening is made in the wall opposite to it. Beside a main channel, which runs through the whole extent of the floor occupied by the dunghill, and terminates in the reservoir by the opening in the wall, a number of similar channels, of five or six inches deep, and of equal width, tending obliquely towards the main channel, is to be formed, well paved, and filled with brushwood, before the dung be laid down. Through these channels the redundant liquid is conveyed to the reservoir.

In laying out and constructing a dunghill, its longest side should run from east to west, should be surrounded by a wall, and covered with a thatched roof. To prevent the effects of the sun's rays, the wall on the south side is raised to the height of the roof; but, on the other three sides, it is sufficient to raise it five or six feet from the ground; and the roof may be supported with pillars of wood or stone. The upper part of the building may be employed as a poultry-house, a pigeon-house, or in some other useful way. By this construction, the dung is prevented from being scattered about, the action of the sun and air is obviated, and every soluble matter that escapes passes into the reservoir, from which it is drawn up by the pump, to be carried to the field, mixed with other substances, or returned to the dunghill itself.

Decomposition promoted.—In laying up the materials of which farm-yard dung is composed, with the view of promoting its speedy decomposition, it is of no small importance that they should be intimately mixed; and here, although it is attended with additional labour, the method of constructing hot-beds, in which the materials are carefully blended, and lightly laid together, may be advantageously imitated. By laying it up in this way, and moderate watering, it is well known that the dung of a hot-bed is as completely decomposed in three or four weeks, as that in a farm-yard, by the usual management, in four or five months. No animals, not even poultry, should be allowed to go upon it. The cart-load, as it is carried out, should be laid down by the side of the dunghill, and afterwards laid regularly and lightly upon it with a fork; and when it is laid up in this way, with a sufficient quantity of moisture, the decomposition proceeds rapidly. In dry weather it may be necessary to water it, or a sufficient degree of moisture might be kept up by means of the urine, which might be conveyed from the offices into reservoirs, from which it might be thrown upon the dung. By this management, the complete decomposition of the whole may be effected in six or seven weeks, and the produce will turn out to be one-half more valuable. But where greater attention can be paid to this important business, it has been suggested, that no greater quantity should be formed into one dunghill than what can be collected in the course of a month. At the end of the month it is to be turned over, thoroughly mixed, left to heat for another month, and again turned over, when it is fit for being applied to the soil.

But in the means employed to promote the decomposition of the mass of vegetable and animal matters, some attention is requisite to prevent the process from going on too rapidly, or advancing too far. Observation and experience may decide what is the most proper temperature; and, when this is once known, the whole preparation may be precisely regulated by the thermometer, a convenient form of which, for this and similar purposes, has been invented by Mrs Lovi, glass-blower in Edinburgh.

Quantity of manure increased.—Various methods have been proposed for increasing the quantity of manure. Two of these have been mentioned. The first is, by securing the liquid as it drains from the dunghill, and either spreading it on the soil or mixing it into compost; and the other is, by collecting the urine of the horses and cattle in a barrel or cistern, to which it is conducted by a proper channel. The quantity of manure may be greatly increased by collecting earth, moss, turf, the cleanings of ditches or drains, some of which are found on most possessions, and either laying them in the bottom of the dunghill, by which they are saturated with the moisture which soaks downwards, or by laying them in heaps by themselves, and pouring the liquid of the dunghill and the urine of the cattle upon them. In this way an excellent manure is prepared; and by this management the quantity, in almost every instance, may be doubled.

The quantity of farm-yard dung which is obtained from a given proportion of straw, when the business is properly managed, has been estimated at three to one, or three tons of manure for every ton of straw employed. The weight of straw produced on each acre, varies from a ton to a ton and a half; so that taking the different crops on an average, every acre of ground under a corn crop may afford a quantity of straw sufficient for the preparation of four tons of manure.

Night soil.—This matter forms a very rich manure, and, when applied unmixed, it ought to be used in small quantities; but it is recommended to mix it with saw-dust, peat-moss, or a portion of earthy matter, by which it may be more equally distributed. When a certain proportion of lime is added, it is soon deprived of its offensive smell, and rendered so dry that it can be easily applied as a top-dressing. Two cart-loads of night-soil, with ten loads of earth, and one of lime, are a sufficient quantity as a top-dressing for an acre. This compost forms an excellent manure to a light soil, destined for wheat or barley. It should be employed early in the spring for wheat, and it may be either harrowed in with the seed, or spread on the young barley crop. A compost of this kind is peculiarly adapted to drill crops.

Pigeons' dung, &c.—The excrementitious matter of birds, and particularly of pigeons, has been long accounted a valuable manure, and is found peculiarly beneficial for a cold, stiff soil. For the purpose of equal distribution, it should be broken down small, or mixed with earthy matters. The proper time for its application is during moist weather, and, as well as other manures, should be covered in by harrowing, when that work can be conveniently executed. The dung of poultry is somewhat of a similar nature, and may be employed in the same way.

Bones.—Bones are advantageously employed as a manure in many parts of England. Sometimes they are applied alone, and sometimes conjoined with other substances. Bones are composed chiefly of phosphate and carbonate of lime, and oily matters, so that they afford, by their decomposition, valuable ingredients for enriching the soil. The bones are used by being bruised, and broken down into small pieces, or reduced to powder. These operations are performed by mills, similar to those for reducing hard substances to powder. After this preparation, they are laid upon the field in small heaps, at regular distances, and covered with earth; having remained for some time in this state, they are spread on fallow, grass, or turnip land. This manure succeeds best on a deep clay, or loamy soil. Powdered bones are extremely convenient for drill crops, because they can be inserted at the same time with the seed.

Horn, &c.—This substance, containing a larger proportion of animal matter than of lime, is a still more powerful manure, and particularly in the form of shavings or turnings. The composition of hair, woollen rags, and feathers, is somewhat similar, so that these substances may be applied to the same useful purpose. The refuse of manufactures of skin, leather, and glue, as furriers clippings, curriers shavings, &c. is also valuable manure.

Putrid animal matters.—Dead animals being covered up with five or six times their bulk of soil, mixed with one part of lime, after a few months become an excellent manure. The offensive smell may be obviated by adding a little fresh quick-lime when they are removed. The refuse of shambles may be treated in the same way. An active manure is obtained from different kinds of fish, as herrings and pilchards, but it must be employed in small quantities, or mixed with sand or soil, otherwise the crop may be too luxuriant; and in some cases, where such matters were applied in excessive quantity, it has been entirely lost. Greaves, or the refuse of the candle-manufacturer, and blubber, are valuable substances, when mixed up with earthy matters, for enriching the soil.

Sect. III. *Of Saline Manures.*

Various saline substances are employed for the purpose of manure, but they are chiefly in a state of combination with other matters, as the refuse of different manufactories. The refuse of bleachers contains a portion of alkaline matter; and, from the active nature of this ingredient, it is necessary that it should be well mixed with eight or ten parts of fresh mould, or peaty earth, and with a certain proportion of rotten dung. From a compost of this kind a valuable manure is obtained. Soapers waste, beside the alkaline matters in its composition, contains a considerable quantity of lime, and may be treated in the same way. A manure of this description is of great use on stiff, clayey, and loamy soils. The ashes of fresh vegetable substances contain also some alkaline matter; and being mixed with vegetable mould, or peaty earth, in large proportion, they afford a rich manure, and are very effectual as a top-dressing to grass-lands. Soapers waste spread on mossy or peaty soils, has proved one of the most active and speediest applications for promoting their decomposition, and converting them to vegetable mould.

Soot.—Soot, in consequence of the carbonaceous and oily matters, and the ammonia, or volatile alkali, which it contains, is also a very active manure. The quantity employed for the acre is from 20 to 40 bushels; but in the neighbourhood of London, where it is extensively used, 30 bushels are considered as a complete dressing; but if dung, or any other manure, have been applied to the same crop, the quantity of soot is reduced to a half, or about 15 bushels. Soot is said to answer best for wheat when applied in the month of April, or on pease or clover at the same time, or when sown with barley and harrowed in. It is recommended as a useful application, at any period in the spring, for the destruction of grubs or worms, and when thinly distributed on newly sown turnips, just before they come up, prevents the injury which they sustain from the fly. The soils to which this manure is most suitable are those of a light, dry, and chalky nature, and the best time for inserting it is during showery weather.

Common salt.—The use of common, or sea salt, has been strongly recommended by some as a powerful manure, while others, keeping in view its antiseptic property, consider its effects to be of a doubtful nature. The high price of salt in this country must be a serious objection to its extensive use; but it is generally employed in combination with other matters, as the refuse of the salt manufactory in Cheshire, or of the processes of the curing of pilchards in Cornwall, or of herrings in other places. The animal matters, in the latter instances, may be supposed to contribute their effects; but those who have had experience of these substances as a manure, always select such as contain the largest proportion of salt. A portion of sea-salt adhering to sand collected from flat shores, or mud in the vicinity of rivers and salt marshes, has been often found highly beneficial in enriching the soil, and improving its productions. In Cornwall, abundant crops of turnips have been produced by the use of salt; but some doubts are entertained, whether part of the effect ought not to be ascribed to the destruction of the slugs, which was the consequence of its application. In some cases, where salt was employed in large quantities, its effects were injurious, but in a smaller proportion they appeared to be highly beneficial.

Sect. IV. *Of Compost Manures.*

Two or more of the various earthy, vegetable, animal, and saline substances which have been mentioned, being blended together in different proportions, form compounds which are extremely valuable as manures. In this way, not only the quantity of the manure is greatly increased, but its quality is much improved. Some of the ingredients which, when employed singly, would be almost useless, after being mixed with other matters, and subjected to certain changes, form a most excellent application for improving and enriching many soils.

All manures may perhaps be considered as compounds, at least after they are applied to the soil; and it might be a question, whether the benefits which they afford to vegetation could not be increased, if some of the changes which they undergo were previously completed, or whether these benefits arise at the time when the new combinations are effected? but this question, which is of great importance, and of no small difficulty, must depend for its solution on a more perfect knowledge of the process of vegetation itself, as well as those changes and combinations which are effected by the mutual action of the different matters employed as manures.

Some of the methods of forming composts, and of increasing the quantity of manure, have been already described; and, in general, it may be remarked, that they are formed of almost every kind of vegetable and animal matter, mixed with earthy and saline substances, which being thrown together in considerable masses, promote the decomposition of the organised materials; and it is scarcely necessary to add, that the collection and preparation of such compound manures must be regulated by the nature and abundance of the matters which can be obtained.

In making a compost with one kind of manure, and a portion of soil, the two substances are placed in alternate layers, in the form of a long ridge; and it should be so covered at the top, that the rain may be prevented from washing through it; but if both lime and dung are used, a layer of earth should be interposed between every two beds of lime and dung, that the excessive action of the lime may be obviated. When the decomposition of the dung is completed, the whole should be turned, that the ingredients may be well mixed, and the same operation is to be repeated till the mass is sufficiently reduced.

The quantity of this compost may be increased, by collecting all the weeds before they run to seed from the neighbouring fields, and adding them to the heap, and the weeds which grow upon it should be buried down in it before they flower and produce seeds.

A compost is also formed, by ploughing and harrowing a head land till the soil is well divided. Forty bushels of lime, fresh from the kiln, are arranged in an equal number of heaps, along the middle of the head land, at the distance of four feet from each other. The heaps are covered with four or five times their quantity of pulverized earth, which is clapped close down with the shovel, to prevent the access of rain or air. The lime is slaked in a few days by the moisture of the earth, and when any cracks or fissures appear, by the swelling of the heap, they are to be covered up with more earth. When the lime is reduced to powder, it is intimately mixed with the earth. This is done in the form of a long bank or ridge, in the middle of which a large furrow is left, capable of receiving five cart-loads, of forty bushels each, of farm-yard dung. The mixture of earth and lime is thrown over the dung, that the whole may be entirely covered. In this state it remains for some months, when it is to be turned over, well mixed, and formed into a heap.

Sweepings of streets and roads.—The fertility of the lands in the neighbourhood of great towns, is kept up by the manure which is collected from the streets and houses. The high price which is paid for this manure, is an ample proof of its value. Made up of almost every kind of vegetable and animal substance, it is perhaps the most compound manure that is employed.

The value of the sweepings of roads depends partly on the ingredients of which the road is formed, and partly on the quantity of excrementitious matter which is dropped by animals; and as the latter is most abundant in the neighbourhood of large towns, the best manure of this description is collected in such situations. When the stones of which the road is constructed are of basalt, or whin-stone or lime-stone, the decomposition of these earthy matters forms of itself a good manure; but its value is greatly increased in the form of compost with vegetable and animal matters, with which it is usually combined. By collecting these matters, the advantages, in preserving and improving the roads, would not be less considerable than in enriching the lands in their neighbourhood.

Compost of peat-moss.—As peat-moss consists chiefly of vegetable matter, when its entire decomposition is effected it constitutes a very valuable manure. Considering it in this view, Lord Meadowbank has particularly described the methods of its preparation, of which the following is an abstract. The compost of which the peat-moss is to be formed, should be dug out for some weeks or months, that the redundant moisture may evaporate, which, by rendering it lighter, diminishes the expence of carriage, and requires a smaller proportion of dung. The peat-moss is then carried to a dry spot, convenient for constructing a dunghill to serve the field to be manured. It is laid out in two rows, with an intermediate row of dung, which occupies the space of the compost dunghill; and the rows should be so near, that the workman may be able to throw them together with the spade. A layer of peat, 6 inches deep and 15 feet wide, if the breadth of the ridge admit of it, is first formed. A layer of 10 inches of dung next succeeds, then 6 inches of peat, then 4 or 5 of dung, and then 6 more of peat; then another thin layer of dung; then cover it with peats at the end where it was begun, at the two sides, and above. The height should not exceed 4 or 4½ feet, otherwise the weight may be too great, and check the decomposition. The workmen continue adding to the compost as they are furnished with the three rows of materials; they must be careful not to tread on the mass, which would render it too compact. When the peaty earth is wet, it should be made up in lumps, and less broken.

Proportion of ingredients.—When the weather is mild, 7 cart-loads of common farm-yard dung, in a fresh state, are sufficient for 21 cart-loads of peat-moss; but in cold weather a larger proportion of dung is required, because more heat is necessary. To every 28 cart-loads of the compost, it is useful to throw above it a cart-load of coal, peat, or wood-ashes; but when such ashes cannot be procured, half the quantity of slaked lime, in fine powder, is a good substitute. The dung employed should be fresh, or kept in a fresh state by compression, as by the treading of cattle, or of carts passing over it. If the quantity of litter be small, a smaller proportion of dung answers the purpose, provided any addition of vegetable matter can be made, as fresh weeds, rubbish of a stack-yard, stems and leaves of potatoes, the sawings of timber, &c. A greater or less quantity of compost is obtained by the state of the dung, as it is more or less advanced in the process of decomposition. By employing the refuse of shambles, six times the quantity of moss may be converted into manure. A similar proportion is obtained from the dung of pigeons, and of domestic fowls; and to a certain extent, from the dung collected in towns, and made by animals that feed on grains, the refuse of distilleries, &c.

Progress of decomposition.—When the compost is made up, the temperature increases according to the state of the weather and the condition of the ingredients. The heat comes on in summer in about ten days, but in the severe cold of winter it requires as many weeks. In summer sometimes the temperature rises so high as to consume the materials, when what is called *fire-fanging* takes place. When such a change is apprehended, a stick should be kept in different parts of the mass, which being occasionally examined, indicates the increase or diminution of temperature; or what answers better, is the thermometer, constructed by Mrs Lovi of Edinburgh, which we have already recommended, and with the aid of which the changes of temperature can be precisely ascertained. If the temperature approach to or exceed blood-heat, the mass should be watered, or turned over, and at the same time an addition of fresh moss may be made. In the progress of decomposition, the heat, according to various circumstances, at last subsides; the mass remains untouched till within three weeks of the time of applying it to the land, when it should be completely turned over, and all the lumps broken down. It heats a second time, but soon after cools, after which it is fit for use. Excepting the pieces of decayed wood, the whole appears a black free mass, which spreads like garden mould. When this compost is employed weight for weight as farm-yard dung, it has been found, in a course of cropping, fully to stand the comparison.

When a compost is made up before January, if the frost be not severe, or long continued, it is ready for the spring crops; in summer the preparation is completed in eight or ten weeks, and the decomposition is greatly promoted by adding lime, rubbish of old buildings, or lime slaked with foul water.

Quantity applied.—The richness and condition of the soil, and the season in which the manure is applied, have varied the quantity of this compost; but from 23 to 35 double cart-loads include the extremes of the proportion which has been used for the acre. The smaller proportion has been given to fallows and ground in good condition, and the larger proportion when it is ploughed in with the sward of poor soil. The intermediate quantities were used with crops of tares, pease, and potatoes.

It is properly stated by Lord Meadowbank, that too much attention cannot be given to the preparation of the ground to which this compost manure is to be applied. It should be clean, dry, well mixed, and friable; for, in any other state, it requires a larger proportion of manure. The addition of a small quantity of well prepared compost, has produced a wonderful effect on land well prepared by a fallow. The texture, colour, and other qualities of the soil, undergo a very preceptible change. All this, it is added, must proceed from the mutual action of the different ingredients in the manure and in the soil, and the various decompositions and combinations which are the result of that action; and it is quite obvious, that all this must be greatly promoted by bringing the minute particles in the soil and manure into contact by intimate mixture.

Compost of peat, lime, and clay.—In the year 1786, Mr Arbuthnot, mentioned above, collected 1000 cart-loads of peat-moss (about 300 tons,) of which was formed an oblong square, 70 or 80 feet long, from 14 to 18 feet broad, and 6 feet high. To this were added 30 bolls lime-shells from Sunderland. The shells were introduced by cutting trenches across the bed of moss, and covering up one trench with the moss which was thrown out of the other. When the whole lime was covered up, a considerable quantity of water was added, and in two or three days the mass took fire. About 150 tons of wet clay, in lumps, were then thrown on at random. At the end of four or five days, the bed was covered up with clay sods, and it remained untouched for eleven months; at the end of which time, when it was carried to the field, the heat was so great that it could scarcely be handled. The compost thus prepared was laid on $7\frac{1}{2}$ acres of grass land, sown with clover and rye-grass three years before. The grass was greatly improved, and the land was not broken up for six years afterwards. The field was several times in corn and grass; and the grass was always cut and never pastured, without receiving any manure till 1810.

In concluding the history and application of different manures, we shall give a short view of some curious experiments conducted by the Reverend Mr Cartwright, which shew the effects of different manures on the same soil, and for the same crop. One object of these experiments was, to ascertain the effects of salt in promoting vegetation. The soil was a ferruginous sand, which was brought to a proper texture and consistence by a liberal covering of pond mud. Four hundred grains of this soil contained 280 of siliceous sand, 104 grains of finely divided matter, and 16 of loss in water; of the 104 grains, 18 were carbonate of lime, 7 grains of oxide of iron, 17 grains lost by burning, and the remainder silica and alumina.

On the 14th of April 1804, a portion of this soil was laid out in beds, a yard wide, and 40 yards long. Of these, 25 were manured, the first excepted, as follows.

No.		No.	
1.	No manure.	13.	Salt, lime, sulphuric acid.
2.	Salt, $\frac{1}{4}$ peck.	14.	Salt, lime, peat.
3.	Lime, 1 bushel.	15.	Salt, lime, dung.
4.	Soot, 1 peck.	16.	Salt, lime, gypsum, peat.
5.	Wood ashes, 2 pecks.	17.	Salt, soot.
6.	Sawdust, 3 bushels.	18.	Salt, wood ashes.
7.	Malt dust, 2 pecks.	19.	Salt, saw-dust.
8.	Peat, 3 bushels.	20.	Salt, malt dust.
9.	Decayed leaves, 3 bushels.	21.	Salt, peat.
10.	Fresh dung, 3 bushels.	22.	Salt, peat, bone dust.
11.	Chandlers greaves, 9 lbs.	23.	Salt, decayed leaves.
		24.	Salt, peat ashes.
12.	Salt, lime.	25.	Salt, chandlers greaves.

The quantity of each ingredient was the same as when they were used singly. On the same day a single row of potatoes was planted in each bed; and that the experiments might be accurately conducted, the number of sets was the same. A few days after, the plants appeared above ground; on the 14th of May they were carefully examined, and the comparative excellence of each row, according to appearances, was noted. The best row was No. 7. from malt dust; the next was from chandler's greaves; bnt we shall not detail the farther results of this examination. On the 28th of May, 14 days afterwards, the rows of plants from malt dust and chandler's greaves still retained their superiority. The most backward row at this time was that manured with saw-dust.

On the 21st of September the potatoes were taken up, when the produce of each row was as follows:

No. 17.	Salt and soot, produced	240
11.	Chandlers greaves	220
18.	Salt, wood ashes	217
16.	Salt, gypsum, peat, lime	195
15.	Salt, lime, dung	199
2.	Salt	198
25.	Salt, greaves	291
4.	Soot	192
10.	Fresh dung	192
20.	Salt, malt dust	189
5.	Wood ashes	187
23.	Salt, decayed leaves	187

Manures.

24. Salt, peat ashes	185
7. Malt dust	184
14. Salt, lime, peat	183
19. Salt, saw-dust	180
22. Salt, peat, bone dust	178
9. Decayed leaves	175
13. Salt, lime, sulphuric acid	175
21. Salt, peat	171
8. Peat	159
12. Salt, lime	167
1. No manure	157
6. Saw-dust	155
2. Lime	150

It is observed by the author of these experiments, as a remarkable circumstance, that of 10 different manures, most of which are of acknowledged efficacy, salt, whose effects were doubtful, is, with one exception, superior to them all; and, in combination with other substances, no other manure besides chandlers greaves was injured by it. The effects of salt combined with soot were very striking; and Mr Cartwright is disposed to ascribe these effects rather to the power of attracting moisture from the atmosphere, than to any chemical action between the two substances; for the beds on which salt was used continued visibly moister, even for weeks after its application. Another circumstance noticed is, that the plants which grew on the beds manured with the salt were of a paler green than the rest, but equally luxuriant, which appearance, he at first concluded, indicated a want of vigour; and wherever salt was applied, either by itself, or in combination, the roots were perfectly clean, which was not the case with those in the other beds.

The same ingenious agriculturist instituted two sets of experiments with turnips and buck-wheat, on a soil so poor that it produced only dwarf heath and lichen. Of 400 grains, 320 consisted of siliceous sand, 68 of finely divided matter, and 12 of loss in water. The finely divided matter lost nearly half its weight by incineration, and the remainder was composed chiefly of aluminous and siliceous earths, coloured with oxide of iron. Scarcely any calcareous matter appeared. On the 6th July 1804, the beds selected for each set of experiments were respectively sown with turnips and buck-wheat. They were numbered and manured exactly in the same way as in the first set of experiments with potatoes. On the 20th July, numbers 1, 2, 4, 5, 6, 7, 19, 20, 21, 22, 24, 25, shewed little or no marks of vegetation; the remainder were merely in the seed leaf. On the 16th of August four only were alive, and in rough leaf, viz.

No. 12. Salt and lime.
13. Salt, lime, and sulphuric acid.
14. Salt, lime, peat.
16. Salt, lime, gypsum, peat.

These four continued in a sickly state till the middle of September, soon after which they disappeared. The appearance of the turnips and buck-wheat was very nearly the same; but no certain conclusion can be drawn from these experiments with regard to the effects of salt as a manure for such crops, for other manures of undoubted efficacy also failed. The inference to be deduced from the whole, is, that a proper texture and consistence of the soil is an essential requisite in promoting the health and vigour of plants, which was abundantly obvious in the greater luxuriance of those plants where the manure tended to improve that texture and consistence.

These experiments may serve as a model to those who have the inclination or leisure to investigate the effects of different kinds of manure on the crops to which they are applied; and although many of the experiments were made on substances which are procured with difficulty, or are to be had only in small quantity, and therefore cannot come into general use, yet the results obtained are curious and interesting, and, if farther examined, may lead to some valuable practical application.

Implements.

Chap. V. Of the Implements of Agriculture.

The almost endless variety of implements which have been invented and proposed for the purpose of abridging agricultural labour, or of performing it with greater accuracy and neatness, could not even be enumerated within a moderate space; but such enumeration would be an idle waste of time. Many instruments of this description have been laid aside as soon as they were tried; and the existence of others has been only prolonged by the fond partiality of their inventors, the desire of novelty, or the power of fashion. It seems no arduous task to form an opinion of the real utility of such implements. A machine of a cumbersome form, of a complicated construction, or of difficult management, may be at once pronounced unfit for the purposes of husbandry. For simplicity of construction and facility of application may be regarded as their essential character, and indeed of all others from which any practical advantage is to be expected.

Sect. I. *Of the Plough.*

The plough is an instrument for turning up the soil, by the power of horses, or other animals, and it is contrived to save the time and labour of man in preparing the ground and fitting it for the reception of the seed. The plough may be considered as a most important and valuable substitute for the spade. Diversity of soil, and of local circumstances, may produce variations in the manner of using the plough, but still there is a similarity in the operation, which gives a certain uniformity to the chief parts of the instrument, from which the principles of its construction are to be deduced. The seeming coarseness of the operation, or the clumsiness of the task of turning up the soil, has probably been the cause of the inattention and neglect which this implement long experienced. It has been considered as a rude instrument, because it could not be supposed that there was any nicety in a business which is succesfully performed even by the most ignorant. The importance of the machine is admitted by others; but from the complicated nature of the operation, and the uncertainty of the resistances to be overcome, or the little knowledge which we possess of estimating the kind and quantity of these resistances, the difficulty of constructing a plough upon undoubted principles is regarded as insurmountable, and its improvement

Implements.

is consigned either to experience or accident. This difficulty, it is acknowledged, is great; but it is not beyond the reach of mechanical ingenuity to overcome it. The preparation which the ground requires for the reception of the seed, and for the support and nourishment of plants, is pretty distinctly known; and though no instrument of the plough kind, can, by its operation, bring it into this state, yet none is ignorant that some ploughs greatly excel others in performing this task. The imperfections of their performance, or what defects remain to be supplied, are sufficiently understood; and as the operation depends on mechanical laws, the solution of the problem is brought within certain limits.

Action of the plough.—A distinct description of the operation of the plough, will serve to indicate what the general form and construction of this implement ought to be, the material parts of which must be found under every variety to which particular circumstances can give rise. The operation of the plough is not conducted by digging, but by being pulled along. The reduction of the soil to that friability and uniformity of which it is susceptible by means of the spade, is not aimed at; but it is brought into such a state that the ordinary influence of the season may finish the task. A slice or sod is cut from the firm land, which is pushed to one side, that the plough and the ploughman may proceed in their labour; the sod is turned over, that the grass and stubble may be buried and rot, and a fresh soil may be left on the surface, which should be so loose and open that it may become friable from the effects of the weather, without running to lumps, or retaining water. The first action is performed by the *coulter*, which makes a perpendicular cut; the point of the *sock* follows, and its edge passing under the sod lifts it up, and at the same time heels it over away from the firm land. The mould-board advancing, pushes it aside, and gradually turns it over as far as may be required.

Form of the plough.—The general form of the body of a plough is that of a wedge or blunt chissel. To render this form intelligible, it is necessary to describe the different parts of which the plough is composed. In Fig. 1. Plate 3. AB is called the beam; CD the stilts or handles, one of which is fixed in the beam; EF is the coulter, which is firmly fixed by its shank E. into the beam; GI is the sheath, the front of which is sharp, forming the edge of the wedge; HK is the mould-board; HL the base or sole, which is pointed at H, to receive a hollow shoeing of iron called the sock, and tapers towards L, which is called the heel. This piece is called the *head* of the plough. The back of the plough is usually called by ploughmen the *land side*, and the side formed by the mould board, is called the *furrow* side. The wedge-like form of the plough may be still more distinctly understood from Fig. 2. in which a plan of the same plough is given. AB is the beam; CD the stilts; EFI the mould-board; GH the sock. This form being attentively considered, it will appear that if the wedge be drawn or pushed along, keeping the edge in the perpendicular cut which has been previously made by the coulter, the point will raise the earth, turn it to one side, and throw it over; but as the wedge raises the earth, the earth presses down the wedge, and, as the wedge pushes the earth to the right hand, the earth presses the wedge to the left. In this way the plough is strongly pressed, not only to the bottom of the furrow by its sole, but also to the solid land by its back or land side. It is pressed into an angle formed by the perpendicular and the horizontal plane of the implement; and hence the furrow becomes a firm groove, directing the motion of the plough, and giving it such a resistance as shall enable it to perform all parts of the operation. This circumstance should be kept in mind, because it suggests a fundamental maxim in the construction of the plough, which is to make the land side an exact plane, and the sole, if not plain, at least straight from the bottom to the heel.

Implements.

Breadth of the sole.—The width of the furrow is determined by the breadth of the sole at the heel, and nine inches afford sufficient room for a horse and man to walk in. A greater breadth is of no advantage, so that force is lost in pushing the earth aside. A broad sole, as has been supposed, does not give more room for the turned slice to stand on; for whatever may be the breadth of the furrow, the successive slices are left at their former distances, because each is pushed aside at the same distance. When the breadth of a slice is greater than its depth, and is turned on its side, it stands on a narrow base, but higher and looser, which is desired by the farmer. When this happens, it generally falls on its back before it has been far enough removed, and is then turned aside, and left with its sward downwards, which is wished to be avoided; but, on the other hand, when the depth considerably exceeds the breadth, the sods, being turned on their sides, are squeezed home to the ploughed land, which breaks and tosses them up, producing coarse work; and if the soil be a wet clay, it is apt to be kneaded together. It appears, then, upon the whole, to be the best rule to have the breadth and depth nearly equal. The sole is generally level from right to left at the heel; and, from this construction, a furrow with a flat or level bottom is formed. With the same view, the land side of the plough should be held perpendicular, instead of heeling it over to that side, as is sometimes done, by which a ribbed furrow, or an irregular formed sole is produced.

Length of the plough.—Various opinions have been entertained with regard to the length of the plough. Considering it as a pointed or cutting instrument, acting obliquely on a given length of sod, its length being increased, adds to its power, for it requires less force to draw it through the ground; but as the earth must be turned aside at the same time, if the length be doubled, it must act on a double quantity of earth at once. It is found that the force required for pushing a mass of earth horizontally along the rough ground, is nearly equal to its weight. Nothing, therefore, seems to be gained by lengthening the hose of the plough, except a greater facility in the first penetration, which is chiefly performed by the coulter and sock; and, besides, a greater length renders the plough cumbersome and heavy. A long plough, which has a more extensive support, both on the land side and below, is less affected by ine-

Implements.

qualities, and has therefore a great advantage in the steadiness of its motion. It is now usual to make them considerably longer than formerly; and, according to the most approved construction, it has been assumed as a just proportion to have the length 33 inches by 9 inches in breadth.

Some advantage is derived from making the plough taper forward, where it acts as a boring and cutting instrument. For this purpose it is convenient to give the coulter a slope of 45°, by which the stones and roots, which it would otherwise push before it through the firm ground, are thrown up. For a similar reason, the edge of the feather, which is an appendage to the sock, having a cutting edge on the furrow side, extending back about ten inches, and to the right hand of the furrow side about six, for the purpose of cutting the sod below, and detaching it from the ground, as the coulter separates it from the unploughed land, has a great slope. But this advantage cannot be pushed too far, without other risks; for as it is sometimes necessary to incline the plough to the right, to get over some obstruction, the coulter must be raised, and a slanting cut made by the feather becomes the directing groove for the plough. When the slope of the feather is very long, this groove has force enough to guide the whole plough; and it is scarcely possible for the ploughman to prevent it from running out of the ground, to the land side. The length of the feather, then, should not exceed 10 or 12 inches.

Construction of the mould-board.—As the chief resistances are exerted on this part of the plough, and must be overcome, it requires the nicest consideration what is the best form for diminishing these resistances, while the operation is well performed. The task required is, to raise, push aside, and turn over, to a certain degree, a slice, which is already cut off from the solid ground. As every inequality of the cohesion or tenacity of the earth cannot be estimated, it may be considered as uniform, which is always the case with its weight; and as every proportion between the tenacity and the weight cannot be provided for, an average, or medium proportion, which is not far from that of equality, may be taken. If, then, the slice be conceived at first as only tenacious, and without weight, it is not difficult to determine the form which gives it the intended twist and removal with the least force. In the same way, the weight of a slice, without tenacity, may be determined. Both may be easily combined in any proportion; and the composition on the supposition of equality of weight and cohesion, is easiest made. If the slice be supposed to be in the form of a brick, the greatest force is required to begin to raise it on one edge, and the force diminishes as it rises, till the centre of gravity is perpendicular to the supporting angle. No force is required to raise it farther, for, in pushing it in the smallest degree beyond this position, it falls over of itself, unless retained by the tenacity of what is not yet raised. But observing the form or plan of the sock, it will be found, that when the weight of the sod has the strongest resistance, there is less of it in this situation actually rising, and this nearly in the same proportion with the trouble of raising it. After the sod has attained that position in which it is ready to fall over, it has reached the wider part of the rest, and is now pushed aside, which requires nearly the same force as to raise it. All these circumstances being considered, it seems probable, that the compound resistance changes little from first to last, and, if this be the case, it may be adopted as a maxim, should proceed equally. If it does not, there must be some part of the sod that makes a resistance greater than the medium; and, as the resistances in this kind of motion increase nearly as the squares of the velocities by which they are overcome, it may be demonstrated, that power is lost by rendering them unequal. Hence is deduced the maxim, that as the plough moves through equal spaces, the twist and lateral sliding of the sod should increase by equal degrees. This is the principle according to which Mr Small constructed his ploughs, which have deservedly attained so much celebrity. But, for the particular rules of constructing the mould-board, we must refer to Mr Small's treatise on the subject.

Bridle of the plough.—The bridle or muzzle of the plough is a curved piece of iron, which is fixed to the end of the beam, by means of a bolt, and to this bridle the swingle-tree, or cross-tree, is attached by a hook. Sometimes the bridle is fixed to the beam by two bolts, and has notches, by which the hook of the cross-tree may be placed either to the right or to the left of the beam; and there are different holes for the hinder bolt, by which means the line of draught is directed, either above or below the beam. In this way, by shifting the hook of the cross-tree to the right or to the left, a broader or a narrower furrow is taken, and by shifting the bolt, the bridle or muzzle is raised above or sunk below the beam, and the plough goes deeper or shallower, as shall be required.

Trim of the plough.—The plough is said to be in *trim*, and to *swim* fair, when it goes on steadily, without any effort of the ploughman; for then the pressure before and behind the centre of action is balanced. To know whether the plough be under this management, the draught-rope is to be hooked as high as possible, and in this state the plough should have a continual tendency to rise at the heel, and to run into the ground. When the rope is hooked as low as possible, the plough should press hard on the furrow with the heel, and have a tendency to run out of the ground. If both these circumstances are observed, the construction of the plough is, in this point, correct; if otherwise, the position of the sock, or of the beam, requires alteration. The tendency of the plough to go deeper, is corrected by lowering the end of the beam, or raising the point of the sock; and as the point of the sock should not be removed from the plane of the sod, the alteration by the beam should be preferred. The slope of the coulter has also a considerable effect, but it cannot deviate far from an angle of 45° without danger of choaking the plough with roots and stones driven before it. If the coulter of the plough be out of the direction of the plough's motion, it must tend to twist it into its own track, and as it must be fixed in the middle of the beam's thickness, to give it strength, it is removed a little from the plane of the land side; and to compensate for this, it was usual formerly to point it to the left; but this position did not obviate the tendence to twist. The remedy for this inconvenience, contrived by Mr Small, is to give the coulter a short knee to the left, immediately below the beam, and thus to point it downwards in the perpendicular of the land side.

Rotherham plough.—This plough, it is said, was invented or improved by Mr Foljambe, of Eastwood, in the West-Riding of Yorkshire, about the year 1730; and from bearing the name of the Dutch plough, it is supposed that it was originally introduced into England from Holland. It is still in very general use in Yorkshire. Mr Foljambe obtained a patent for this plough; but it was afterwards set aside, on the ground that it was only an improvement, and not an original invention. Fig. 1. Plate 3. is a representation of this plough, of which a description has been already given. Fig. 2. is a plan of the same plough. AB is the beam; CB the larger handle or stilt fixed to the beam; DE the smaller handle; EFGI the mould-board; GH the feather of the sock or share; K an iron rod to give strength to the handles.

Small's plough—James Small, the improver of the plough which bears his name, was born about the year 1740, in the county of Berwick in Scotland; finished his apprenticeship under a country carpenter and ploughmaker in the same county; went to Doncaster, and wrought for some time with a waggon and wheel-carriage-maker; and, after his return in 1763, settled at Blackadder Mount, in Berwickshire, where he commenced the business of agricultural implement maker. At the same time he had a considerable farm in his occupation, which gave him the best opportunity of carrying on his experiments. At this time the old Scotch plough was the sole implement in use in that county. Some writers, who seem disposed to detract from Small's merit in the improvement of the plough, are anxious to prove that his claim is to be limited to the introduction of the Rotherham plough, or merely to its revival; for it is asserted that it was known in Scotland as early as 1730, about the time that it was improved by Foljambe in England, by means of an itinerant ploughmaker of the name of Lummas, or Lummis. When Mr Lummis constructed his ploughs we are not informed; but it is added, that the same kind of plough was made by Mr Dalziel in Linlithgowshire, who had been sent to England at the expence of Lord Stair, to be instructed in the best methods of constructing agricultural instruments. From this it appears that Mr Lummis's improvement in the plough had twice fallen into oblivion, and was first restored by Mr Dalziel, and afterwards by Mr Small. But there is something not very distinct in this account of the origin and progress of Small's improvement.

On the other hand, it is strenuously contended by the friends of Small, that the old Scotch plough was the foundation on which he proceeded; and in support of this opinion, the similarity of construction between the Scotch and the improved plough, and the testimony of those who were witnesses of the experiments which he conducted, are adduced. But, at the same time, it is admitted that he was well acquainted with the Rotherham plough; and is it not extremely probable, that, in contemplating the means of improving that implement, he would be desirous of studying the advantages and effects of every plough which he had an opportunity of subjecting to his examination?

Fig. 3. Plate 3. is a view of Small's plough. AB is the beam, CB the left handle, DE the coulter, GH the sheath on which is fixed the sock or share DFG; GHIK the mould-board; AF the sole. Fig. 4. is a plan of the same plough: AB the beam; BC the left handle, DE the right handle; FG the mould-board; I an iron rod which connects the two handles.

The materials of which Small's plough was originally constructed were similar to those of other ploughs; but about the year 1780, he added another improvement, by forming the mould-board and the land-side plates of cast iron; and finding these to answer the purpose so well, he extended the use of the same metal to the sheath and head. The most difficult parts of the plough being put into the hands of the workman ready made, the construction became easy, and its use spread rapidly over Scotland. But the introduction of this plough, like many other useful inventions and valuable improvements, at first met with great opposition. When this was overcome, many ploughmen in Berwickshire were so convinced of the superior advantages of this plough, that for their own ease and satisfaction they offered to be at the sole expence of the wood work, if their masters would furnish them with Small's plough, and defray the other charges. After the use of Small's plough became general in his native county, he settled in Mid-Lothian; and the attempt to introduce it met with similar opposition. A comparative trial of his plough with several others took place near Dalkeith, in presence of a great assemblage of gentlemen and farmers from the surrounding counties. It was decided that his plough did the best work with the least power. The superiority of his plough being thus publicly acknowledged, its use spread rapidly over Scotland, and it has since been extended to many parts of England, as well as to Wales and Ireland, and even to some foreign countries. The late Lord Kames was a warm patron of Small, and in his Gentleman Farmer strongly recommended his improved plough, which he says is now in great request, and with great reason, as it avoids all the defects of the Scotch plough. Before the introduction of this improved instrument, every plough in use required not fewer than four horses or oxen, or a couple of each of these animals, and sometimes more, besides a driver and other attendants; but with Small's plough, two horses and the ploughman are only necessary.

Advantages of Small's plough.—The great superiority of Small's plough arises from the neater and lighter construction of its different parts, the improved combination of these parts, and the exact coincidence of the line of draught and the centre of gravity of the plough. The sock and mould-board are formed according to strict mechanical principles; those parts which enter the earth, have an equally tapering or sharpened wedge like form, which produces the least resistance in raising the furrow-slice; and the mould-board is so curved or twisted, that the friction is diminished, and the furrow-slice is raised and turned over into its most proper place. The an-

Implements.

terior part of this plough is a very thin wedge, so that it cuts the furrow-slice from the fast land with the smallest possible resistance. Aided by the broad thin feather of the sock, which separates the slice below from the sub-soil, and the mould-board gradually increasing the wedge form, the slice is gradually turned over, so that the whole resistance is not met at once.

But the superiority of Small's plough has been fully established by various comparative trials. In an experiment before the Dalkeith Farming Society, it was found, that Small's plough when it operated on an old ley, was drawn with a force of from nine to 10 Cwt. while the old Scotch plough in the same field required a force of 16 Cwt. to execute the same work. In another experiment made before the same society, January 18. 1810, in which a plough improved by Mr Veitch was brought in competition with Small's, it appeared, that a power of draught equal to $3\frac{3}{4}$ Cwt. measured by the dynamometer, applied to the former, produced a furrow of $7\frac{1}{2}$ inches deep; and the same power applied to the latter formed a furrow of $8\frac{1}{2}$ inches deep, and of the same breadth. Another experimental trial of Small's plough in competition with one brought forward by Mr Simpson, exhibited before some members of the same society on June 19. 1813, afforded a still farther proof of its superiority; for it appeared that the latter required a greater power of draught, amounting to nearly $\frac{3}{4}$ Cwt. to perform the same work. Small's ploughs are still made by the sons of the improver, at their manufactory, Leith Walk, Edinburgh.

This plough is sometimes entirely constructed of iron. The chain which was applied to it, seemed to serve no other purpose than giving strength to the beam, and is now very generally disused.

Mr Liston's plough.—A plough invented by the Rev. Mr Liston of Ecclesmachan, and for which that gentleman has obtained a patent, differs from others, first in the form of the mould-board, and, second, in the application of a wheel. 1. The different mould-boards, it is observed by the patentee, which are made by tradesmen, are formed rather by guess than according to any fixed rule; and although they all perform the work proposed, it occurred to him that a mould-board constructed on the principle of adapting the curve to the varying resistance of the furrow to be turned over, would possess many advantages. The undoubted superiority of the work executed by this plough, and the ease of draught obtained, are properly stated as satisfactory proofs of the correctness of the principle on which the construction has proceeded.

2. The diminution of friction is another advantage connected with this plough. This is effected by means of a wheel set at an angle to the horizon, running in the corner of the furrow, and answering the ends both of sole and side-plate, although we understand that some practical farmers have used the plough without the wheel, and have not perceived much difference in its operation.

The advantages of this plough are stated to be, the better performance of the work, with less labour to the horses. The superiority of work consists in the depth of the furrow, and in the complete manner in which the slice is taken out from side to side. On examining the operation of other ploughs, it appears, that although the furrow may be pretty deep on one side, yet great part of the soil is left fast on the other. Wherever deep ploughing is required, as in fallow, the superiority of this plough is universally acknowledged; and it is said that his ploughs, in fallow, can execute as much work as three of any other description, with a clean furrow, and half as deep again. These are valuable properties, and, from authority which we deem unquestionable, we have been assured that they belong to this implement, the advantages of which we suspect have not yet been fully appreciated. Mr Liston's plough is constructed by Mr Morton, agricultural implement maker, foot of Leith Walk, Edinburgh.

An objection has been made to the use of this instrument, in ploughing ley ground for a seed furrow, that the work is too large, or that there are too few *seams* for the reception of the oats or other seed. The objection, it is admitted, is not altogether inapplicable to the plough, as it is at present constructed; for it was calculated solely for strong soils, with a deep and large furrow. But a smaller instrument could easily be made on the same principles; and this task, should leisure and encouragement offer, we understand the ingenious inventor has it in contemplation to undertake.

Sect. II. *Of the Harrow.*

After the operation of the plough, the fresh surface frequently requires to be broken down and pulverized, for the reception of the seed; and when the seed is inserted, it must be covered up. For these purposes, harrows of different weight, and somewhat different in construction, are employed.

Brake harrow.—The brake is a large and heavy harrow, which is used in breaking down stiff soils, as in fallow operations, where the ordinary harrow would have little effect. Some of these have been constructed with four square bulls, each side 5 inches, and $6\frac{1}{2}$ feet in length. The teeth are 17 inches long, 12 inches free below, with a heel close to the under part of the bull, to prevent them from being pushed back, and they are secured above with a screw nut. Five teeth are inserted into each bull, so that the whole number is 20. The teeth bend forward like a coulter; but a brake composed of five bulls, and having six teeth inserted in each, is now more commonly employed; and a harrow of this description is drawn by two horses. The construction of the brake with joints, renders it more commodious for the rounding of the ridge.

Uses of the brake.—In the operation of fallowing stiff clay soil, where a repetition of ploughing is necessary, a braking between each ploughing is of great advantage in pulverizing the soil, and in facilitating the succeeding parts of the labour. In March or April, when strong soil which is overrun with couch-grass and other weeds, is prepared for barley, a cross braking is considered preferable to cross ploughing; and the expence is much less. After ground which has been broken up for the first time, has been cross ploughed, the application of the brake is very effectual in reducing the whole to a proper texture.

Implements.

The harrow has been constructed of different forms and sizes according to the nature of the soil, and the work to be performed. The following is a description of an improved harrow.

Improved Scotch harrow.—Fig. 5. Plate 3. is a plan of an improved harrow. ABCDEFGH, are two harrows connected together by a crank or hinge at L and O, at the extremities of the iron bolts KL, LM, NO, and OP, which pass through two of the bulls in each harrow, and are secured by a nut. Each harrow consists of four bulls, each bull containing five teeth, or tines, making altogether, in the pair of harrows, 40 teeth. A cross bar, AT and CW, in each harrow, is fixed to three of the bulls, to give sufficient strength to that part from which it is drawn. VW is the chain to which the cross-trees are attached. The rhomboidal form of this harrow prevents the teeth behind from running in the track of those which have preceded them. Each tooth has its own distinct track, and all the tracks are at equal distances, as will appear by casting the eye on the figure, from which, and the annexed scale, the proper dimensions may be obtained. Fig. 6. is a profile view of one of the bulls: AB the bull; C the end of the chain which is attached to the cross tree; DF and EG the first and the last teeth. This set of harrows obviates the defects of those of the common form; and being connected by the hinge, they accommodate themselves to the curve of the ridge. For the purpose of covering grass seeds, smaller harrows, with short teeth, are recommended by some, while, by others, the common harrow is supposed to be quite sufficient for this work.

Operation of harrowing.—In the operation of harrowing different soils, and in different conditions, two or more implements, as it may be thought necessary, are wrought together. On stiff soils, two only should be employed, otherwise the work is less perfectly executed by their irregular action; and, on strong coarse soils, as the velocity adds to the effect, the horses should proceed as fast as they can easily walk.

When the harrowing is for the purpose of covering the seed, the greatest attention should be paid to perform the work in a regular and steady manner; and particularly to keep the teeth of the harrow clear from all obstructions, such as grass roots, unbroken masses of earth, and stones, by which the seed is thrown together in crowded patches in some parts of the field, while bare spots appear in others.

To perform the operation of harrowing perfectly, the furrow should be broken, and the surface rendered smooth. The first harrowing is usually in the direction of the ridge lengthwise; the second is conducted transversely or across the field; and the operation is finished by repeating the longitudinal course. Those who are anxious to have the work neatly executed, take care to have the last harrowing precisely in the direction of the ridge.

Sect. III. *Of Drilling Machines.*

Various machines have been constructed for the purpose of depositing grain, pulse, or other seeds, in rows, at equal distances; but few of those which have been invented at different times are found to accomplish the task with the requisite degree of accuracy and regularity. In the construction of machines of this description, simplicity of form, that they may be easily managed by ordinary labourers; cheapness, to admit of being generally employed; regularity in depositing the seed, without bruising or breaking it, and being accommodated to different distances, to suit the size of different seeds,—are the principal circumstances which ought to be attended to. Drill machines vary in form, according to the number of rows which they sow at one time, the distances between the rows, and the kind of seed deposited. In general they are drawn by horses, but sometimes they are moved by the labour of man. The choice of implements of this kind must be regulated by the nature of the soil and situation, the size of the farm, and the kind of grain cultivated; but simplicity of construction, from which the best work may be expected, should be always kept in view.

Numerous instruments have been constructed for facilitating the drill husbandry, as drill-ploughs, drill-rakes, universal sowers, horse-hoes, &c.; but as many of these implements are extremely complicated, and are therefore deficient in the essential character which can render them useful, we shall only describe the drill-roller, the drill-harrow, and the drill-barrow.

Drill-roller.—This roller, which it is supposed was invented in Norfolk, is so contrived as to form regular incisions, or drills in the soil, of a proper depth for the seed. It is a common roller of iron, of about a ton weight and seven feet long, about which are put cutting wheels of cast-iron, which turn round the common cylinder, and are unconnected with each other. The roller is drawn by three or four horses abreast, and driven by a man raised behind them. The cutting wheels are moveable, and, by means of washers, may be fixed at any requisite distance.

The length of the roller may be varied, according to circumstances, and the ribs may be deep or shallow, according to the depth of the drills, and the distances of the rows. The common length is from seven to eight feet; and, if the distances are eight inches, the roller contains 12 ribs. The usual diameter of the roller is 12 inches.

Mode of operation.—The method of operating with this implement is the following: When the ground is ploughed which is intended for setting or dibbling, the roller is drawn across the furrows, and divides the whole field into drills, according to the distance between the cutting wheels. The seed is then sown broadcast, in the usual proportion, and the land is bush-harrowed. In this way the seed is deposited at an equal depth, as in drilling, and the crop rises free from the furrow-seams, which is always an inconvenience connected with the common method of broadcast sowing.

Advantages.—The use of this simple implement is held out as a great saving of both time and expense, and affords all the benefits which are derived from the operation of drill-ploughs, or other complicated apparatus, or from the practice of dibbling, and setting corn by the hand. A man and three horses, it is said, can cover five or six acres of corn in one day. The drill-roller was at first chiefly employed on clover or other grass leys, on the first ploughing; but it is stated to be equally applicable to land which has been several times ploughed.

Drill-harrow.—Fig. 7. Plate 3. is the profile or elevation of a harrow which answers well for cutting weeds and pulverising the soil between the drills: B is the plan of the same machine; C is the profile, and E the plan of the front share; D is the profile, and F is the plan of the hinder share. These shares can be placed at a greater or less distance, according to the width of the drills, as may be seen by consulting the plan B, Fig. 7.

The drill-harrow is a useful instrument for cleaning potatoes, turnips, and other crops in drills; for it both cuts the weeds and harrows them to the surface. Comparing it with the scraping and paring plough, one-half of the expense is saved.

Drill-barrow.—This implement is for the purpose of sowing grain in drills. Fig. 8. Plate 3. is a representation of the various parts of a machine of this description: A is a profile or elevation: B is a plan of the same implement; C is an end view; D is an edge view of the seed-wheel; E is the profile of the same wheel with flutes or channels to receive the beans, and also a brush made of stiff bristles, placed above the wheel, to cause the seed to drop regularly into the bottom of the furrow; F and G, different views of the seed-wheels for sowing oats, barley, wheat, and pease. These different wheels may be placed on the axle or taken off at pleasure, according to the kind of grain to be sown.

This drilling implement is constructed by Messrs Small, Leith Walk, and by Mr Morton, at the same place, at the price of from two to three guineas. The box should contain from a peck to a peck and a-half of grain. The fluted rollers are made either of wood or of cast-iron, which is preferable to having the brushes closer.

Sect. IV. *Of the Grubber.*

Various implements, under the denomination of *scarifiers*, *extirpators*, *cultivators*, &c. have been invented for the purpose of stirring the surface of land and preparing it for the seed, with the view of saving the time and expense of a ploughing. The following is a description of a machine of this kind, called the *grubber*, which has been successfully employed by Mr Dudgeon, in Prora in East Lothian, in Scotland, and is drawn up, at the desire of the Highland Society of Scotland, by Mr John Shirreff.

Construction.—This implement consists of two strong rectangular frames, the one including the other, and nine bars mortised into the inner one, with 11 coulters or tines, with triangular, sharp-edged, dipping-feet; four cast-iron wheels, two handles, &c. The machine is made of various sizes, and elm is reckoned the best wood for the frames and bars. The dimensions of Mr Dudgeon's grubber are the following: See Plate 3. Fig. 9. which is a profile of the implement, and Fig. 10. which is a plan of the same.

	F.	I.
Length of the outside frame -	6	9
Breadth of the frame -	3	6
Square of wood of frames and bars	0	3
Long hinder swing-tree, K K	5	10
Short hind do. N N -	3	6
Coulter's length - -	2	2
——— breadth - -	0	$1\frac{1}{4}$
——— thickness - -	0	$0\frac{7}{8}$

The inner frame is moveable on hinges, fixed on the front beam of the outer; and it has two sides or beams, into which are mortised nine cross-bars, about eight inches distant from each other. The coulters are fixed in these bars, excepting two, which are placed in the side-beams of the outer frame. The openings for the coulter have plates of iron, above and below, for strengthening the wood, with top and heel wedges attached by chains; and when the machine is at work, these wedges are firmly fixed, to steady the coulters. The machine is supported by four cast-metal wheels, each 20 inches in diameter, and they prevent the coulters from going deeper into the soil than the pitch at which they are set by the pins and wedges. The wheels are also necessary for moving the machine from one place to another: and in going down a declivity, the fore-wheels should be dragged, to prevent it from running against the horses. When the instrument is to be removed from one place to another, the screws AA, Fig. 10. are turned to allow the inner frame to rise on the hinges near EE. The inner frame is raised by the handles B B, and supported by small iron-stays, which are hung on staples CC, and stretch to others on the under side of the bars DD, Fig. 9. When the implement is at work, these stays lie across the frame, and are fixed in other staples at EE, Fig. 10. To strengthen the inner frame, two rods of malleable iron, headed at both ends, run from near DD to near EE, Fig. 10. The two coulters fixed in the side-beams of the outer frame must have the wedges slackened, and be raised close up to the under side of these beams, and fixed there, when the instrument is moved from one place to another. At FF, Fig. 10. in the outer frame, bolts are driven upwards, with screwed points, and fastened with corresponding screws. The lower ends of these bolts have eyes or round holes, for fastening the extremities of the chains HH, which are attached to the large swing tree at KK. The soam L is fixed below the inner frame at G, passing through a strong staple under the outer frame at M. NN are small swing-trees, to which the two hindmost horses are yoked. The coulters stand reclined, and have steel triangular feet, as may be seen at Fig. 9, and under different views in the separate figures Q, Q, Q. They are from three to four inches broad at the base, and from five to six inches long from the base to the point of the triangle. The beam PO, Fig. 9. of the inner frame, must have the under edge rounded off, to allow it to rise by the handles.

Use of the grubber.—To work, and thoroughly stir summer fallows, or land on which potatoes or turnips have been raised, or lands ploughed in autumn or the winter, and which are intended to be sown with grain or pulse in the spring, with the exception of clover and other leys, are the important purposes to which the grubber may be applied. Sowing on the winter furrow has been objected to, because the effects of a spring ploughing to clean the ground are lost. It is no favourable indication of the state of the ground which renders spring ploughing necessary, with this view; but in such cases the grubber will be found a valuable instrument: For grounds in such a condition can be effectually stirred as deep as the plough goes, and all root weeds which have remained in the soil are cut up, and drawn to the surface, by the reclining position of the coulters, and sharp edges of their feet, instead of being partially buried by the operation of ploughing. The grubber acts as a powerful harrow, with the additional effect of its sharp edged triangular feet; and it does not materially alter the relative position of the particles of the soil; and hence it affords a decided advantage over the plough for working winter ploughed lands in the spring, particularly those of a strong nature, for the valuable part of the mould is retained on the surface for the reception of the seed. By the use of this instrument, time, and consequently expense, are saved; early sowing is obtained; no fresh seeds of annual weeds are brought near the surface; and a drilling apparatus might be connected with it, to deposit grain or other kinds of seed.

Advantages.—In cases where lands have been laid down with cultivated herbage seeds, as red-clover, &c. and have been broken up and cropped with oats, which are to be succeeded by beans, if the oat stubble have been ploughed down in the autumn, or early in winter, the land may be afterwards advantageously wrought by the grubber in spring, and the beans put in by a separate drilling apparatus, or one attached to the grubber itself; and if a skim-coulter were employed to bury the oat stubble under a strong deep furrow, the grubber would afterwards complete the operation. Beans, pease, and tares, have been sown on the winter furrow, merely by working the land with the grubber; and in some cases the land, after sowing, has been wrought and cleaned very effectually with this instrument. The feet were so set as not to reach the seed, which was drilled; but if the operation be not delayed till the roots have taken hold of the soil, it may be employed without injury, both in drill and broadcast crops.

The grubber is also found extremely useful in aiding the operations in the preparation of land for potatoes or turnips, as well as for summer fallow. Land which has been previously ploughed in winter, or early in the spring, when it is of a friable nature, may be cleaned and pulverised as soon as the dry weather sets in, by means of the grubber. When the ground is foul, the instrument may be set to work only a few inches deep in going over the field the first time, and the coulters may be placed deeper and deeper as they can be applied. After two operations of the grubber, in very foul land, it is found necessary to use the plough, which is to be followed by the grubber again, till the land be as clean as can be effected. In a strong soil, a second ploughing, to be succeeded by rolling, may be required before the cleaning process of the grubber can be repeated. When stiff soil has been twice ploughed and rolled, the root weeds are, in almost all cases, loosened and brought to the surface by the grubber. When there is much couch-grass in the soil of a field, it may be divided into several compartments by plough furrows; in crossing these, the inner frame of the instrument can be raised up, and the root weeds, collected by the coulters, disengaged from them. These weeds, being deposited in parallel rows, are collected by a rake, to be scorched or carried off the field.

An instrument of this kind may be applied to work across and level down the ridgelets formed in horse-hoed drilled beans, after the crop is removed, and previously to ploughing down the stubble. The grubber effectually exterminates couch-grass or other root weeds left in a bean fallow, and which are usually found on the tops of the ridgelets, lurking among the stems of the beans. The levelling of the ridgelets, which admits of the land being ploughed with more facility, correctness, and expedition, is effectually accomplished by means of the grubber.

If seed can be advantageously inserted in a very dry autumn, in strong land, by means of the scarifier instead of the plough, it cannot be doubted that it may be more easily done on moderately loamy soils by the grubber, and in all soils of a softer texture, early in spring, before they are hardened by the drought. If fewer coulters were employed, if it had only five or six instead of 11, and if it were only half the breadth, and the same power applied, this instrument might probably be used in the preparation of land after turnip, for the reception of barley and grass-seeds, to better purpose than the plough, by stirring the soil completely, while the seeds of annual weeds are not brought near the surface.

These implements are drawn by four horses, and they are constructed by Messrs Brown and Carrick, farm implement makers in the village of Athelstoneford, East-Lothian. The price of grubbers of the strongest construction is from L.11 to eleven guineas; and they are also made by Mr Morton, Leith-Walk, Edinburgh.

Sect. V. *Of the Roller.*

Rollers are constructed of wood, cast-iron, or stone; and they are drawn over the surface of the land by means of horses, for the purpose either of reducing lumps or clods, or for compressing porous soils that their texture may be improved. The roller is employed both for tillage and grass lands; and the weight and size are different, according to the different uses to which they are applied.

The common roller is about five or six feet long, and from 15 to 30 inches in diameter; but when it is intended for flattening one *bout* ridges, to prepare them for drilling turnips, it is made shorter and of smaller diameter. A roller of cast iron, and divided into two parts, is recommended as one of the best construction. The length of each of the parts is from three to three and a half feet, so that a surface equal to six or seven feet is covered. It exceeds 10 Cwt.; the frame is strongly made, with shafts for a single horse, to be fixed on the near side, and hooks placed on the other side for an additional horse when necessary. The gudgeons, or pivots, act upon small case-hardened friction wheels, two of which are fixed on each side of the frame, with a small roller of hard wood, about nine inches long and three inches in diameter, bound with iron at the extremities, and fixed to the back part of the frame, that both rollers may act with each other in the centre

Implements. wheel. In this way, while the large roller is kept steady, the draught is at the same time greatly diminished. The obvious advantage of this roller is, that it rises and falls in the centre, and thus accommodates itself to the slopes of the ridges.

As rollers do not move upon their axis, but are drawn along the surface of the ground, they are apt to tear it up, and to make cavities and depressions before they come into the line of draught, to which they are brought with some exertion, when they are turned at the ends of ridges or fields; the roller now described, from being constructed in two pieces, is supposed to obviate these inconveniencies; and when formed in this way, it is recommended that the cylinders be made of cast-iron.

The spike-roller, which is constructed in the same way as the common roller, except that it has a number of spikes inserted in it, is considered a very efficient implement in reducing strong stiff soils, breaking down the lumps, and bringing the land into a fine state; and a compound roller, composed of the plain and spike rollers, which may be used either singly or together, is also found highly beneficial in producing the same effects. Its powers, it is said, are wonderful, in pulverising stiff clay soils. It gives the farmer a command over dry seasons, and enables him to sow his spring and fallow crops in proper time, and to clean his arable land of root and annual weeds. A roller of this kind, passed over the land once, twice, or thrice, with drag-harrowing between every rolling, renders it sufficiently fine for every purpose. This roller is also found extremely useful in restoring degenerated sward.

The furrow roller, which is a double cone, united at the base, has been constructed for the purpose of rolling the furrows in hilly and other lands which are not accessible to the common roller.

The size and weight of rollers, it is obvious, must be varied according to the nature of the soil and the particular purpose for which they are intended. When the roller is of large size, a greater weight becomes necessary to make any impression, because it is divided over a more extended surface, and when the roller is small, it is apt to produce depressions and inequalities on the softer and more yielding parts of the soil. It would therefore be of great advantage to have rollers of different sizes, and by increasing or diminishing their weight they can be accommodated to all purposes.

Operation of rolling.—In rolling ground with a roller composed of a single piece, the operation is most conveniently performed by going round the whole field in a kind of spiral direction; for in this way the necessity of making short turns is obviated. This is the best method of rolling down grass seeds with corn crops. Grass lands may be rolled in any direction; but perhaps, in all cases, the most convenient and effectual practice is, to roll transversely or across the field, so that the benefit may be extended to the land next the furrow, which is rarely the case when the operation is conducted along the ridge.

Advantages of rolling.—As the object of rolling is to render the soil more solid and compact, and thus to improve its texture, as well as to give it a smooth and even surface, the operation should never be performed in wet weather, particularly on adhesive soils, which are apt to stick to the roller, and to render the surface rough and uneven; but when it is employed in a favourable season, it is of great use in breaking down the hard masses of earth which are turned up in fallowing. It is not less beneficial in the preparation of land for turnips, and it is equally useful to grass lands after they are cleared of stones. A heavy stone-roller, drawn by two, or even by three horses, is required for strong clay soils; but for grass or turnip land, a wooden or cast-iron roller, drawn by a single horse, is sufficient.

SECT. VI. *Of Reaping Machines.*

The usual method of reaping corn by means of manual labour with the sickle or scythe, is often attended with much inconvenience and loss, not only from a deficiency of hands when the crop is fully ripe, but also from the shaking of the grain before and during the operation. These circumstances have suggested the notion of constructing a machine, by which that important work might be accomplished with more safety and expedition. Many attempts have been made for this purpose, but till lately none of them promised to be successful. The splendid premium of L.500 Sterling, which was offered by the Dalkeith Farming Society, a few years ago, to the person who should invent and construct an effective machine for reaping corn, roused mechanical ingenuity, and brought forward a great number of models and machines; but few of them, even from a slight examination of their principle and construction, were calculated to produce the effect. Some of these models or machines operated by means of knives; some by means of scissars, and others by circular cutters; but they were all deficient in one or both of the essential properties of such an apparatus, namely, in the perfect cutting and regular laying of the grain. The only machines of this description which appeared to be constructed on a correct principle, and have been found upon trial to answer the end, are those of Mr Smith, manager of the Deanston cotton-works, near Doune, in Perthshire, and of Mr Kerr, mathematical instrument maker in Edinburgh. Of these machines, the principle of which is exactly the same, we shall give a short description.

Mr Smith's reaping machine.—Fig. 1. Plate 4. is a perspective view of Mr Smith's reaping machine. AB is the frame work, which supports the cutter D, and the machinery by which it is put in motion. C is a conical drum, made of tin-plate or basket work, two feet deep, and about five feet diameter at its lower part, to which the circular cutter D is attached. The drum is covered on the outside with canvas; and perpendicular pieces of soft rope, about an inch thick, and three or four inches distant from each other, are stitched upon it, to increase the friction in carrying round the cut corn. The circular cutter D consists of six segments, which are secured in their place by screw-nails, and can easily be taken off to be sharpened. They are made of German steel, and project five inches beyond the lower part of the drum. The motion is communicated to the drum and cutter by the wheels E E, through the intermediate action of the horizontal shaft FF; and this latter puts in motion the upright shaft, to which the drum and cutter are attached. The horses which propel the machine are yoked to a transverse bar, which is fixed at the extremity of a pole, running back from the frame of the carriage, and they draw by means of common plough chains directly from the cross-bar, or, what is considered as an improvement, by cross or swingle trees. The back weight of the carriage is supported on common cart saddles, with an apparatus similar to that used in curricles.

Operation.—An inspection of the figure will shew that the carriage wheels, by a series of wheels, pinions, and shafts, communicate, in proceeding forward, a rapid rotatory motion to the drum and cutter; and as the cutter projects beyond the carriage-wheels on each side, a sufficient breadth is cut down to permit the carriage and horses to pass along without injuring the uncut corn. The corn is cut by the rapid motion of the cutter; and as the lower ends of the stems rest upon the edge of the cutter, and the heads come in contact with the drum, the whole is carried round, and regularly laid by the side of the machine. The lower extremities take the ground first, the heads fall outwards, and the stalks are laid parallel to each other, and nearly at right angles to the line of motion of the machine. The man who drives the horses walks behind, and guides the whole machine by the end of the pole. By a particular apparatus he can raise or lower the cutter, when any obstacle comes in the way, or in going from one field to another. The cutters require to be sharpened four times in reaping an acre; and this operation is performed in two minutes with a common scythe stone.

When the machine is to be removed to a distance, the upright spindle, with the drum and cutter attached, is taken from its place, and secured on the top of the carriage. The cross bar at the extremity of the pole is removed, and fixed in a mortice near the frame of the carriage, and the horses are turned, to draw from it, so that the machine may travel to any distance, and over any kind of road.

In the trials which have been made with Mr Smith's machine, it appears that it is capable of cutting down an English acre of corn in the hour, during which the cutter, as already mentioned, requires to be sharpened four times. The expence of a machine of this description is calculated at L.30 or L.35 Sterling; but it is supposed that, with proper care, it may be kept in use for many years. The only additional expence will be a new set of cutters every second or third year.

Mr Smith made the first trial of his machine on a small scale, during the harvest of 1811, and it was then wrought by two men. In 1812, he constructed a machine upon a larger scale, wrought by a horse. Several acres of oats and barley were cut down with considerable ease. It was found that the power of a single horse was unequal to push it forward on rising ground. During this harvest, Mr Smith exhibited his machine in operation in the neighbourhood of Dalkeith, before a committee of the Dalkeith Farming Society, from whose report it appeared that the corn was well cut, but was not laid with sufficient regularity. In the succeeding year, 1813, the machine was still farther improved, when it was wrought by two horses and one man. It was again exhibited before a committee of the Dalkeith Farming Society, who reported that the corn was better laid, but was imperfectly cut. In the harvest of 1814, some additions were made to the apparatus, for the purpose of regulating the application of the cutter when it is employed on unequal ground. This addition consists in wheels or rollers, placed under the cutter, by which it is prevented from sinking into the earth on a rough surface. But the most successful trials with Mr Smith's machine were made in the harvest of 1815, some of which were in the presence of a committee of the Highland Society of Scotland, who gave a most favourable report of its operation; and as an acknowledgment of their opinion of Mr Smith's ingenuity, a piece of plate of 50 guineas value, was presented to him by that respectable body. In the trials alluded to, a Scotch acre of beans was cut down in an hour and a quarter. Satisfactory trials were also made in reaping wheat and oats, the latter of which was laid with the most perfect regularity, at right angles to the path of the machine. The operation of this machine in cutting corn is attended with the great advantage, that the grain is not in the least degree shaken; so that the loss which is frequently sustained by the common mode of reaping with the sickle is entirely avoided.

Mr Kerr's reaping machine.—This machine, of which a perspective view is given at Fig. 2. Plate 4. consists of two principal parts, 1st, the carriage, and, 2d, the drum, with its appendages. The carriage is mounted on three wheels, and is partly of wood and partly of iron. The two front wheels are made very heavy, in order to give power to the cutter. The rim is about six inches broad. These wheels move upon a strong axle, which has a catch to carry round the axle with the wheels when the machine is pushed forward, but so fixed as to leave the axle free when the machine is drawn backwards. Upon this axle the two bevil wheels are fixed, only one of which is shewn in the figure at D. They are so placed that either of them may be brought into action, and thus the motion may be reversed at pleasure. The ends of the main axle move in couples, connected with a strong bar, or bars, passing below the cutter to the frame of the machine. A broad upright beam, or frame work, E, is attached to the bar immediately behind the cutter, on the top of which the long beam EF rests, and the whole is bound together with straps and bolts of iron, so as to form a strong and durable carriage. The third small wheel is placed near the bottom of the upright frame-work E, and the machine thus resting on the three points, sufficiently distant, is not easily overturned. The horses are yoked to the end of the long beam by swingle-trees at F. The horse was yoked by a swingle-tree at the first trial of the machine in harvest 1811, and this method is found to produce by far the most steady motion. The two guards GG prevent the horses from coming forward on the cutter, in the event of any of the harness giving way.

The drum A forms the other part of the machine, and it consists of a frame with iron arms, which are bounded by a circular rim. The arms are covered

Implements.

on the outside with thin wood, or basket-work, which commences immediately above the cutter B, and is continued as high as the heads or ears of the growing corn. The cutter, or perpetual scythe, B, is fixed to the bottom of the rim. It is sharp on the outside, or outer edge, and is divided into a convenient number of segments, all of the same size, so that a corresponding part may be easily put on, in case of any of the segments being damaged. The drum is carried round upon an upright shaft or axis D, passing through its middle. There is a pinion fixed upon this axis, which pitches in one of the toothed vertical wheels on the main axle, so that when the carriage moves the drum is immediately put in motion. The lower end of the pinion-shaft or axis rests on a part of the frame directly over the middle of the main axle, and the upper end of it is kept in its place by the end of the long beam above, which is produced to E for that purpose.

By this arrangement, the whole forms a strong, compact, and simple machine, of which the new invention of the drum, with the circular cutter attached, makes the most important and distinguishing feature. Many machines have been constructed for reaping corn, by some of which the cutting process has been accomplished; but none of these machines can cut and at the same time lay down the corn regularly, so as to be afterwards operated upon by the thrashing machines now in general use. Both these, however, are done in the most perfect manner by this machine. The stalks of corn after being cut, are laid down with their heads away from the machine, so as to form a right angle with the line of operation, or path of the horses, and by this means they may be easily gathered into sheaves.

Mr Kerr's new invention of the drum and circular cutter attached, was not made very public till the month of February 1811, at which time he exhibited his model in its present complete and simple form. Soon after this, we find it was laid before one of the first agricultural societies in Scotland, and they entered the date of the exhibition upon their minutes, in order to secure to him the merit of the invention. This appears by the following excerpt from the minute-book of the Dalkeith Farming Society, dated 11th April 1811: "One of the members having mentioned that he had seen a very ingenious model of a reaping machine, which the inventor, Mr Kerr, mathematical instrument maker in Edinburgh, was desirous to exhibit to the Society, for the purpose of securing to himself the priority of invention, in the event of an effective machine being afterwards constructed on the same principles; the meeting agreed that the secretary should inform Mr Kerr that they would examine his model at next meeting." The model was accordingly presented in the month of May following, before a very full assembly, being the anniversary meeting of the Society, and the committee delivered their report, which is also inserted in their minute-book.

In the harvest of the same year (1811) Mr Kerr constructed a large operative machine, and proved the efficiency of the principle of his invention on a field of corn near Edinburgh. The price of this machine it is supposed will not exceed L.20 Sterling. Mr Kerr obtained a premium of 20 guineas from the Highland Society for his model, which was examined by a committee of the directors; and he is to receive a farther sum of 20 guineas when he constructs an improved machine on a large scale. To those who are interested in the perfection of such an implement, it will be gratifying to be informed, that he is now occupied in this labour; and to those who are acquainted with his talents and ingenuity, it is needless to state, that something effectual may be expected from his exertions, and particularly when the various improvements which he has in contemplation have been arranged and embodied. It is proper to add, that Mr Kerr has already taken the preliminary steps to secure the right of his invention by a patent, and we believe it is still his intention to complete the process.

The slightest inspection of the figures of the two reaping machines now described, is sufficient to mark the identity of the principle in both. The construction is somewhat different. But whether the complicated apparatus in the one be necessary to its successful operation we presume not to decide; nor should we deem ourselves free from equal presumption were we to pronounce any decision on the merits of a controversy, which we regret has appeared before the public with regard to the priority of invention and certain improvements on these machines. On one point we have no hesitation in expressing a decided opinion. Since we had an opportunity of seeing Mr Kerr's model, and of witnessing the operation of Mr Smith's machine at Dalkeith, in 1813, we have never entertained the smallest doubt that an efficient reaping machine could be constructed.

Sect. VII. *Of the Thrashing Machine.*

The invention of the thrashing machine has been productive of more real benefit to the agriculturist than perhaps any other instrument at present in use. Besides the immense saving of grain, not only in regard to quantity, but its improvement in quality, he can at all times command a sufficient supply, either for an increasing demand in the market, or in the field in seed-time. From the rapidity with which the operation can be performed, he has it now in his power to attend to it at all times, which formerly, from its very nature, when executed by the flail, became impossible, as it generally commenced immediately after harvest, and continued, according to circumstances, frequently during nine months of the year. Independent of seeing the whole process performed in the most satisfactory manner, under his own eye, the grain is not now required to be in the chaff heap, during the thrashing of a stack, for perhaps ten or fourteen days, on a damp floor, until it is winnowed, but is in general immediately passed through the fanners a second time, which operation, with the thrashing, seldom occupies more than two days, and in many cases it is finished in a shorter time. The advantage derived from the quickness of this operation is perhaps greater with regard to wheat than any other grain; for by lying so long in the chaff heap, it contracted a degree of toughness which rendered it difficult to grind immediately after thrashing; so that it became necessary either to remain on a well aired floor for some time, or to mix it with a larger quantity which had been dried in a similar situation. The grain also acquires a kind of roughness to the touch by lying in the chaff, so perceptible, that few persons who are in the habit of judging of the quality of grain, are at a loss to know whether it has been thrashed by the flail or the machine; an accurate observer assures us, that he has frequently made the experiment in the public market, and has been seldom disappointed in the result.

Origin and history.—The first attempt to construct a thrashing machine seems to have been made about the middle of the 18th century, by Mr Michael Menzies, advocate. This machine, for which the inventor obtained a patent, was erected in the vicinity of Edinburgh, and, after being examined by a committee of the Society of Improvers in Scotland, was approved and recommended by that body. The machinery was driven by water, and the operation was performed by a number of flails, somewhat similar to those which are used in thrashing by manual labour; but it did not answer the purpose, and soon afterwards was laid aside.

The next attempt to construct a machine of this kind was made, about the year 1758, by Mr Michael Stirling, a farmer near Dumblane, in Perthshire. The principles on which this machine was constructed are similar to those of the flax or lint mill. An upright shaft or axle, driven by a water-wheel, has four arms fixed in it, which are inclosed in a cylinder, about 8 feet in diameter and $3\frac{1}{2}$ feet in height. The shaft and arms are moved with great velocity within the cylinder, and the corn, which is presented by the hand, is let down through an opening in the top of the cylinder, that it may receive the strokes of the arms or switchers by which the grain is beaten out, and the straw passes outwards through an opening in the side of the cylinder. The corn falls down into the fanners to be separated from the chaff. This kind of machine, although it is not considered of the best construction for separating the grain from the straw, is still in use in some parts of Scotland.

Two thrashing machines were erected in Northumberland about the year 1772. One of them was invented by Mr Ilderton, at Alnwick, and acted upon the principle of pressing or rubbing out the grain; but it would appear that the work was very imperfectly executed. The other machine alluded to, was constructed by Mr Oxley, at Flodden, and its operation, it is said, was more successful. By some it has been alleged, that Mr Meikle, who is generally considered as the inventor of the thrashing mill, derived the first hint from this machine, which was moved by horses, and the corn was introduced between two fluted rollers, and struck by switchers hung on hinges. The defect of this machine was, that it did not thrash out the grain completely, arising, it is supposed, from the want of sufficient velocity. Before this time, a thrashing machine, upon the principle of the flax mill, was erected in Northumberland, by Mr Gregson, who, it is said, borrowed the idea from a small flax mill, with which a Scotchman travelled the country, for the purpose of swingling the flax which the farmers grew for their own use. Mr Gregson's machine was wrought by a man, who could thrash with it twelve bushels of wheat in a day; but it was found to be hard labour, and the machine was soon afterwards laid aside.

It appears that models of some of the thrashing machines erected in Northumberland, were brought to East-Lothian, one of which was sent to Mr Andrew Meikle, civil engineer at Houston Mill, near Haddington, for the purpose of ascertaining its effects; but on the trial being made, the model was, in a few minutes, broken to pieces; and the machine constructed on a large scale, some years afterwards, shared the same fate. From these unsuccessful attempts, Mr Meikle was probably led to turn his thoughts to the construction of a thrashing machine, upon a different principle from any which had been yet adopted. He employed a cylinder or drum, placed in a horizontal position, and having the switchers fixed upon its circumference, so that it might be enabled to bear the necessary motion; for he was convinced that the corn could not be perfectly detached from the straw without a very considerable velocity in the thrashing drum. The attempt completely succeeded.

The first thrashing machine was erected by the son of the inventor, about the year 1786, at Kilbagie, in Clackmannanshire; and it is not a little curious to observe the doubts which were then entertained of the successful operation of such a machine; for a stipulation was entered into, that the materials were to be furnished by the proprietor, and if the machine did not answer, no remuneration was due to Mr Meikle for his labour. When the machine was completed, it performed the work in a satisfactory manner. Other machines were erected on the same principles; and their utility and advantages being fully established, a patent for the invention was obtained, but proved of little benefit to the ingenious inventor, in consequence of the numerous machines which had been constructed in different parts of the country. Not long since, the ingenuity of Mr Meikle, then in his 89th year, was rewarded by a pretty liberal subscription, which was encouraged and promoted chiefly among the landed proprietors and farmers in the northern part of the kingdom.

Since the invention and first construction of the thrashing machine, various important improvements have been introduced, both by the inventor himself, and by other ingenious mechanics. When it was first erected, although the corn was well separated from the straw, yet as corn, straw, and chaff, were thrown together into the same heap, the operation was only half performed; but by means of shakers and fanners, which have been added to the original machine, and are driven by the same power, the operation of thrashing, shaking, and winnowing, is executed at the same time, and the grain is immediately prepared for the market.

For the following description, as well as for the elegant drawing from which our engraving is taken, of a very complete and perfect thrashing machine, we are indebted to Mr Clark, of Mayfield, near Dalkeith, on whose farm it was erected by Mr Charles Umpherston, mill-wright at Loanhead.

A, Fig. 1. Plate 5. is a table 4 feet long by $3\frac{1}{2}$ feet broad, elevated from the opposite side of the rollers

Implements. about 6 or 7 inches, on which the corn is regularly and evenly spread, and, by being pressed gently forward, is taken in by the rollers B, (4 inches in diameter,) and by their weight and triangular edges is held fast, while the switchers *c c c c*, fixed to the cylinder D, and projecting about 3 inches from its surface, passing with great velocity, beats the grain out in an upward direction against the plate E and breast of the machine F, made moveable by hinges at G. The breast of the machine, from the plate E to the hinge at G, is covered with plate-iron; the cylindrical drum D, and switchers *c c*, are also covered with the same metal. The straw and grain are thrown against the circular shaker or rake H, and by it made to pass over the skreen I, through which the grain falls into the hopper K, while the straw is carried forward to the second rake, or cylindrical skreen L, which separates the remaining grain, and throws the straw upon the inclined skreen M, to the floor of the straw-house N. The grain, by passing through the hopper K, is made to fall into the fanners O, which separate the chaff and grain in the usual manner. After being properly riddled, and the chaff removed, the grain is again passed through the same fanners, which are then moved by a small water-wheel, (entirely distinct and separate from the thrashing machine,) placed under the *troughs;* the velocity of the wind required is regulated by a valve, allowing a greater or lesser quantity of water to fall upon the wheel, which completes the operation.

The whole machine is put in motion by the water-wheel P, 14 feet 4 inches in diameter, and 3 feet 9 inches in breadth, made entirely of cast-metal, excepting the arms, which are of hammered iron, and the buckets of wood, pitched; and which, to thrash the grain in a proper manner, requires to make four and a half revolutions in a minute. The requisite velocity is obtained by the quantity of water allowed to fall into the buckets, by raising or depressing a sluice, which is so constructed as to be near the hand of the person who conducts the operation.

On the inner edge of the water-wheel are placed a number of cast-metal segments, containing 240 teeth, which drives the pinion Q, (2 feet 7 inches in diameter,) of 43 teeth, also made of cast-metal, and placed on the axis of the spur-wheel R, (5 feet 9 inches in diameter,) made of the same materials, having 108 teeth, that drives the pinion of the cylinder D, having 12 leaves. On the axis of the spur-wheel R, are also placed two pinions or sheaves S, (1 foot 10 inches in diameter,) which in the plate are seen through the pinion Q, so constructed as to move the chain-belt T, of the rake H and Y, of the roller pinion or sheave W; the motion of the second rake or skreen, L, is communicated from the rake H, by the two bevelled wheels XX, fixed on the axis Y, and working into the two faced wheels ZZ. The chain-belt V, puts in motion the pinion or sheave W, which by a faced wheel *a*, (see Fig. 2.) working into the small pinion *b*, turns the spindle *c*, to the upper end of which is attached the pinion *d*, which, by the lever *e*, can be made to give motion to either of the face-wheels *f* or *g*, fixed on the axis *h*, by which means the motion of the rollers B can be made to feed in the corn, or the reverse, at pleasure. This contrivance is particularly useful in thrashing grain when the straw is Implements. damp, as it has then a great tendency to warp round the rollers, by reversing the motion, which is done by moving the pinion *d*, (see fig. 2.) by the assistance of the lever *e*, from the face wheel *f*, to that of *g*; the rollers are then made to move in a contrary direction, and to return the straw on the feeding table, with the same celerity that it was taken in by them to be exposed to the switchers of the cylindrical drum. All this is accomplished while the machine moves on in the usual manner; and as soon as the straw has *wound* off the rollers, the operation proceeds, by again moving the pinion *d* into the pitch of the face-wheel *f*, as formerly.

Another advantage attending this construction, is, that the pinion *d*, by being left out of the pitch of either wheels, as in Fig. 2., the motion of the rollers is stopped; and as it seldom happens that the water can be entirely excluded by the sluices from the water-wheel, should the machine be set in motion from such a circumstance, or any other, no danger is to be apprehended from any thing left on the feeding table being taken into the machine, which from the negligence of servants may occasionally take place.

On the same axis *h*, with the bevelled wheels *f* and *g*, Fig. 2. are placed two small spur-wheels, of different diameters, (5 and 6½ inches) fixed together by the box *i*, and, being made to move along the axis, can be fixed at any particular point of it by the screw *k*; as these are made of different diameters, and also to work into either of the two, of different diameters, fixed on the axis *l*, to which the rollers are attached, it is obvious that, by these means, the rollers can be made to deliver the corn to the switchers either in a slow or rapid manner, as may be thought necessary from the length of the straw, the proportion, in this case, being as eight to twelve.

In the machine which we have described, the rollers, drum, and rakes, are made four feet in length; this size has been found, by repeated observations, to be preferable to their being made of a greater length. When the water-wheel moves with that degree of celerity necessary to give the proper velocity to the switchers on the cylindrical drum, it is found fully to occupy one man in feeding the corn to the machine (with his assistants to unbind and place it on the table) in a proper manner; and also sufficient employment to the other persons who are engaged to remove the straw and to riddle the grain. When this is exceeded, nothing but confusion takes place, which it is always adviseable to avoid. The quantity which is generally thrashed by this regular method of working amounts to about six bolls per hour; by employing a greater number of persons, and applying more water, double the quantity could be done in the same time, the corn being supplied in a proportionate manner.

The fanners are moved by a crossed rope passed over a sheave about 11 inches in diameter, placed on the axis of the cylinder D, and two others on the axis of the fanners, of eight and ten inches in diameter, and the rope placed on either of them as occasion may require. The rope is directed by the assistance of the two pulleys, *n* and *o*; and as the one

Implements. at o is made to move up and down in a frame, the rope is by that means kept in the degree of tightness that is requisite. As the axis of the fanners make 47 revolutions for one of the water-wheel, the number is 211 per minute.

In calculating the velocity of the above machine, excluding fractions, it will be found that the cylindrical drum makes about 50 revolutions for one of the water-wheel; and as the water-wheel requires to make 4½ turns per minute, the number of the revolutions of the cylinder is 225 per minute; and as the diameter of the cylinder, including the breadth of the switchers, is 3½ feet, the circumference then is nearly 11, making the velocity of the switchers about 2500 feet per minute.

As the rakes make five revolutions for one of the water-wheel, the number, per minute, is 22½, clearing the skreen (having four arms) 90 times per minute.

The rollers are so constructed by the chain-belts, &c. as to make, when upon the slowest motion, eight revolutions for one of the water-wheel, and when the quickest motion is necessary 12 revolutions; by this it appears, that they will, on the former, make 36 revolutions per minute, and the latter 54; and as they are four inches in diameter, the circumference is somewhat more than 12½ inches, which being multiplied by the number of revolutions per minute, makes, when on the slowest motion, 450 inches of straw to pass through the rollers, and when on the quickest 675; which 675 inches will receive 900 strokes of the switchers in that time, or nearly a stroke and a half to an inch. On the slowest motion, the number is exactly two strokes to an inch; and this has been found, by the present machine, always to beat out the grain in the most satisfactory manner.

As the segments containing the teeth for moving the spur-wheel are placed on the inner edge of the water-wheel of the machine, which we have described, and as it is constructed with eight double arms of malleable iron, a considerable improvement was made in erecting it (from those wheels hitherto made on the same principle,) by placing four stays from the outer arms near the gudgeon to the arms on the opposite side immediately under the buckets, by which means the lateral motion from the spring of the arms is prevented, and the machine moves with a more steady and equable motion. It was found that a stay to every second arm completely answered the purpose.

In erecting machines of this description, it is of consequence, as in the case of the present, where situation and circumstances will allow, to convey the water under ground from the mill-pond to the water-wheel; and as the moving part of the sluice is made so as always to be immersed in the water, no interruption takes place in the time of frost; the water-wheel being at the same time defended from it as much as circumstances permit.

When the water in the pond stands at five feet perpendicular height from the level on which it strikes the wheel, the sluice requires to be elevated only one inch; and as the sluice is exactly 24 inches in breadth, the water, under that pressure, issuing through an aperture of 24 square inches, is sufficient to do the work which has been already described; as the water subsides in the pond, it becomes of course necessary to elevate the sluice in a corresponding degree. Implements.

If, from a scarcity of water, or any other cause, it should be necessary to apply a horse-power to move the machine, we have subjoined the following description of a horse-wheel and shaft, applicable to the construction of the other parts of the machinery, and which may be employed either with a small quantity of water, assisted by horses, or entirely by horses.

Fig. 3. AA cross beams; BBB cross bridges for lying shafts; C coupling box; D barn wall; E wall between arch and horse-way; F water-wheel; G part of horse-wheel.

When the thrashing machine is driven by horses or other animals, it is of great consequence that it should move uniformly and steadily; but this is rarely accomplished, except by well-trained animals, or great attention on the part of the driver; and when any irregularity in the motion arises, from the unequal exertion of the horses, no small degree of care is requisite in the person who feeds the machine to obviate its imperfect operation; but as the labour of working the thrashing machine, when long continued, is severe, the fatigued and languid animals exert themselves unequally, and when urged forward make sudden jerks and strains, which is a great waste of their own strength, and produces a considerable interruption and injury to the machine. To obviate these inconveniencies, a very ingenious and simple apparatus has been constructed by Mr Samuel, of the village of Long-Niddry, in Linlithgowshire. The principle of this apparatus depends on the resistance which a horse or other animal invariably makes to be drawn backwards; and it is so constructed by means of sheaves and pullies, that a connection is formed between the draught-chains or ropes of each animal, whether yoked abreast or at different arms of the machine; and in consequence of this connection, when any one relaxes his exertion, he is pulled back by the shoulders, so that he immediately resists and pushes forwards; and in this way the action of the whole is rendered equal.

Fanners.—The fanners, or winnowing machine, which is now in very general use, was introduced into Scotland by the father of Mr Meikle, the inventor of the thrashing machine, about the beginning of the 18th century. In 1710 he was engaged by Mr Fletcher of Salton, a celebrated character in Scottish history, to proceed to Holland for the purpose of being instructed in the art of making pot-barley, and of erecting barley-mills. After his return, he constructed the first fanners for separating the chaff from the grain that were known in Scotland. The original construction was only a wheel with four vanes of thin boards or sheet-iron, which were made to revolve with considerable velocity within a drum, by which a strong current of air is produced, and the chaff and light grain are blown backwards, while the good grain falls downwards by its superior weight. This machine, which has been also greatly improved, is now very extensively employed, and is usually connected with the thrashing-mill; so that when it is properly fitted with riddles, or harping apparatus, the grain is cleaned, measured, and made quite ready for the market as it comes from the machine.

Small thrashing machine.—On the principle of Meikle's thrashing-mill, Mr William Johnson, an ingenious mechanic, of Langholm, in Dumfries-shire, has constructed a small thrashing machine, which is driven by manual labour, and with two men is stated to be capable of thrashing out 10 or 12 bushels of grain in the course of an hour. The expence of such a machine does not exceed L.8 or L.10; from which it seems well calculated for small farms, if, as some suppose, the moving power required be not too much for human exertion.

Sect. VIII. *Of the Hay-turner.*

A machine for turning hay has been invented by Mr Salmon, of Woburn, in Bedfordshire, which is said to be extremely useful for the purpose for which it is intended, as a man and a horse can do the work of 10 or 12 men in the ordinary way of performing this labour. The following is a description of this implement.

This machine consists of a number of rotative rakes, which are set in motion by one of the wheels which support the whole frame. These rakes are furnished with teeth, which, revolving with great rapidity, raise the hay as they come in contact with the surface of the field, and throw it backwards. The iron teeth are attached to the arms by means of a hinge, and they are kept in their place by the force of a spring, which, yielding to any pressure or obstacle, returns them to their place when the pressure is removed. The machine is so constructed, that longer or shorter teeth may be applied, or a part, or the whole, as the surface of the ground or the nature of the crop may require. This peculiarity of construction is convenient when the machine is moving on a road, or when it is unemployed; for, by turning the teeth inwards, there is no danger of accident to cattle or other animals approaching it. It is stated as another advantage, that the same machine may be made to act as a horse-rake for gathering the hay into windrows, or for raking up stubble.

Fig. 4. Plate 5. is a plan of this machine, somewhat differently constructed. AA are the shafts; BB the frame; CD the wheels, one of which, D, communicates the motion, by the toothed-wheel and pinion *ab*, to the axle EE of the rotative rakes; FFF the arms of the rakes.

Fig. 5. is the profile, or elevation of the same machine. A one of the shafts; B the frame; D the wheel, which puts in motion the rotative rake; *aa* the arms of the rake; *bb* the teeth; *cc* the springs, which return the teeth to their place when the obstacle or resistance is removed; E a third wheel or roller, turning on a centre bolt or pivot.

These machines are manufactured and sold by Messrs Wilson and Company, iron-founders and patent thrashing-machine makers at Leicester; and they are sold also by Messrs Cooke, Fisher, and Company, at their Repository, Winsley Street, Oxford Street, London.

Sect. IX. *Of Wheel-carriages.*

As a large proportion of agricultural labour is performed by means of wheel-carriages, it is of great importance that they should be so constructed as to be capable of accomplishing the purposes for which they are intended, with economy, facility, and despatch. The character of the draught animals, the nature of the work, and the condition of the roads, must, in some measure, affect the form and construction of the carriages employed; but these circumstances, it may be suspected, have often less influence in regulating the form and size of machines of this description, than the prevailing practice in particular districts. As an example of this, the heavy waggons, which are still extensively in use in many parts of England, have been adduced by writers on this subject; but, for the more ordinary purposes of husbandry, where the conveyance is short, carriages of a large size are by no means suitable. More time is required in loading and discharging, and more injury is done to the roads, than when carriages of a lighter construction are employed. The only case in which such carriages can be usefully preferred, and even here the advantage is doubtful, is, when a heavy load is to be conveyed to a great distance, through a level country, and over a good road.

Carriages of a smaller size, drawn by one or two horses, are justly supposed to be by far the most convenient for the purposes of husbandry, when the quantity of labour performed is taken into account, with the despatch which is thus obtained. Such are the carriages which are in general use in Scotland, and such, too, are preferred in some of the best cultivated districts of England; and perhaps the single horse cart, on every account, merits the preference; for it has been shewn, that the same number of horses, when employed in single carts, can draw almost a third more weight than when yoked together in the same waggon. A single horse, with one of these carts, properly constructed, draws from 12 to 24 Cwt., and, when the roads are good, even a heavier load. In the most improved cart of this description, the bottom, as it rests on the axle, projects over the inner heads of the naves, and approaches nearly to the spokes of the wheels. By this extension of the breadth, the capacity of the cart is increased, and the perpendicular position of the lateral standards enables them to sustain a much greater weight. The dimensions of such a cart are usually about five feet three inches in length, four feet in breadth below, four feet three inches above, and one foot three inches in depth. It contains about a cubic yard. The height of the wheels is usually about four feet two inches, and the axle is commonly made of iron. This is called the *close* cart; and what is denominated the *coup* cart, which is pretty common in many districts of Scotland, is so constructed, that the body turns on hinges, and falls down behind, so that the entire load can be at once discharged without unyoking the horse.

It has been justly observed by a practical writer, that single horse carts, which are in use in various parts of England, are the best calculated for every kind of carriage, except large masses of wood or stone, which cannot be conveniently divided into separate loads; and, as a proof of the economy of such carts, they are employed in almost all places where the roads are bad, either arising from soft mud and clay or large stones, and where there are deep ruts, especially in the mountainous districts both of England and Scotland. The same writer, the author of the Agricultural Report of Middlesex, after noticing the large and expensive teams which are indulged in, seemingly for parade and show, in a country which is level, the roads good, and the people rich, adds, that he employs four one-horse carts, each of which carries 25 cubical feet of the gravel of flints, and from 30 to 40 of manure. If farther proof were necessary of the superiority of single horse carts, a striking example is recorded of a carrier at Carlisle, who, after having many years employed a waggon, laid it aside, and now uses single horse carts only, because in this way, with the same number of horses, he can convey a much greater load.

Besides the advantages which single horse carts possess, of being loaded and unloaded with more ease and convenience, and of being more manageable for almost all purposes, the size of the wheels may be adapted, with the greatest exactness, to the height of the horse, and be placed more suitably to the centre of gravity of the load, by which the draught is greatly diminished. For as those parts of the neck and shoulder-blades, on which the collar rests in draught horses, have that degree of slope which forms an angle with the horizon of about 14° or 15°, it is obvious that the line of draught should form a similar angle, because in that case they pull in that line of direction which coincides most with the shape of the shoulders, and consequently the different parts of the shoulders are equally pressed upon; and hence it is, that horses draw more in a sloping than horizontal line of direction. The power or advantage which they have in overcoming the resistance of obstacles, in this direction, is likewise considerable. From these principles it is justly inferred, that single horse carts are far more advantageous than teams, because in the latter many of the horses draw in a horizontal direction, and consequently in a way that is inconsistent with their mechanism. From this consideration, too, it appears, that the wheels in every sort of cart should be properly adapted to the size of the horse or other animal which is employed.

In places where small carriages are in use, different kinds are frequently employed for different purposes. The close and coup cart, which has been described, is chiefly used for carrying out dung, compost, and such compact, heavy, or loose materials; but when bulky loads, such as corn in the straw, hay, &c. are to be conveyed, it is not unusual to have a frame-work, which is fitted for the same wheels, and this kind of carriage is called a corn or hay cart; but it has been stated, that the farmer's cart, as it is denominated in England, as well as most of the small sized carts, and all those of the larger kind, by having ladders attached to them at the ends and sides, is quite sufficient for every agricultural purpose, without the additional expense and trouble of such a number of different carriages.

Irish Car.—This kind of vehicle, which is very generally employed, not only in the business of husbandry, but for many other purposes, in Ireland, from its peculiar construction possesses numerous advantages. It is easily filled; it may be drawn over soft meadow, or ploughed lands, with less injury and inconvenience, and it passes through confined gateways with facility. As the length is but a few inches more than the breadth, it approaches nearly to a square form; the wheels, which are low and broad, are placed under the body of the carriage, and, from the cylindrical form of their rims, the resistance in the draught is supposed to be greatly diminished, by which a heavier load can be drawn.

According to the opinion of many intelligent agriculturists, the wheels of carriages which are employed in husbandry should not be of too large diameter, because low wheels are not only cheapest in their original construction but are also strongest and most durable. In determining the breadth of carriage-wheels, the preservation of the roads has been generally an object of consideration, and it has been suggested, that the rims of the wheels, even of single horse carts, should not be less than five inches broad; and the breadth should be increased in proportion to the load to be carried, and the number of horses required. The form of the rim has been also a subject of speculation. While some suppose that it ought to be conical, it is more generally recommended by others to be of a cylindrical construction.

Sect. X. *Of the Bruising-machine, Straw-cutter, &c.*

Bruising-machine.—Various machines have been invented for bruising grain, for the purpose of feeding horses and other animals; and from this practice great advantage is derived; for it appears that seven parts of the same grain, when bruised or split, are equal, if not superior, to 8 parts employed whole, in feeding animals. One of these machines is composed of two cast-metal rollers or cylinders, from 12 to 16 inches long, and from 6 to 9 inches in diameter, placed in a horizontal position, in one frame. When these cylinders are driven round, the circumference of each rolls upon that of the other, by which the grain passing between them, is bruised or crushed. The frame in which the cylinders revolve, is furnished with screw-bolts, so that they can be placed at a greater or less distance, as the grain is to be more or less bruised. Above, a hopper is placed for containing the grain, and from this it is conveyed by a suspended board to the cylinders. This machine is driven either by manual labour, or by the application of any other convenient power. Mr Pasmore of Doncaster, in Yorkshire, has invented a mill for this purpose, and for which he has obtained a patent. This machine, from the simplicity and durability of its construction, is recommended as not being liable to be put out of order, while its performance is such, that with exertion it will crush a bushel of malt in less than four minutes, and beans, oats, and barley in proportion.

Straw-cutter.—Machines, under the names of straw or chaff-cutters, are employed for the purpose of cutting straw and hay for feeding cattle. They are variously constructed. In some, a strong box, open above, is fixed on the top of a wooden frame, about

Arable land. 6 feet long, 2 feet 9 inches in height, and from 12 to 15 inches in breadth. In this box are placed two small wooden rollers, round which passes a piece of double canvass, and when the rollers are turned round by the motion of the cutting wheel, the straw, which is spread upon the canvass, is carried forward, according to the length at which it is to be cut. Sometimes the knives or cutters are fixed upon a wooden wheel, about four feet in diameter, and sometimes they are attached to the arms of a cast-metal wheel. In some of these machines there are three cutters, in some two, and in others only one. Sometimes the knives cut in a sloping direction outwards, and sometimes inwards to the centre, which is considered as the best mode of operation. A straw-cutter, invented by Mr Salmon, costs about twelve guineas.

A machine for the same purpose, invented by Mr Macdougal of Oxford street, London, is represented as possessing, in a superior degree, facility in working, so that much time is saved in labour; and it has another advantage, that if injured, through accident or carelessness, it can be easily repaired. Mr Pasmore, already mentioned, is the inventor of a patent machine for the same purpose, the different parts of which are so constructed and arranged, that it is not liable to be put out of order, or to be choaked or clogged; and it is obvious that its power of operation is considerable, when it is stated that it is capable of cutting a bushel of chaff in a minute.

The bone-mill is a useful piece of machinery, for the purpose of bruising or crushing bones, where such can be had in sufficient quantity, to be employed as manure. The construction of such mills is sufficiently simple, as they generally consist of toothed or indented rollers; but it is obvious that they must possess, at the same time, considerable strength and solidity.

The turnip or potatoe slicer is a valuable instrument for preparing these roots, as the food of some animals for which they are less proper in their entire form. A machine of this kind has been lately invented in Lancashire, and is considered a great acquisition to those who think this mode of preparing turnips and potatoes advantageous to their live stock. The roots to be cut are placed in a hopper on the upper part of the machine, from which they fall down upon the knife or cutter, which has a double edge, and is moved horizontally. The operation of the machine is stated to be so powerful that more than two Cwt. of potatoes can be sliced in a few minutes. The price of this machine is about L.7.

Chap. VI. Of Arable Land.

In forming any system for the management of arable land, various circumstances must come under the consideration of the husbandman,—as the preparation of the soil,—the kind of crops to be cultivated,—and the order in which these crops should succeed each other. The requisite preparation of land, for the reception of seed, is regulated by the nature and condition of the soil, whether it has been formerly under culture, or whether it be for the first time brought into an arable state; and the situation and peculiar character of the soil direct to the proper selection of the crops to be cultivated, as well as to the order of their succession. These topics may be conveniently discussed under the three following heads of tillage, kinds, and rotation of crops. Arable land.

Sect. I. *Of Tillage.*

Under the general denomination of tillage are included all those operations which are performed by the plough, the harrow, and other implements, and which are necessary in the preparation of the soil for the reception of seeds, and for promoting their vegetation and growth. For these purposes, lands which have been long under cultivation, and are in the best condition, require some preparation. This comprehends the ordinary operations of tillage; but in certain conditions of the soil, as when it becomes foul with weeds, extraordinary labour is requisite to restore it to the proper degree of cleanness; and in certain cases, when a different culture, or a nicer management of certain crops is adopted, as when they are raised in rows or drills, corresponding variations in the treatment and preparation of the soil must be pursued. This suggests the method of considering the operations of tillage under the heads of ordinary tillage, fallowing, and drill husbandry; but as it rarely happens that land which has never been in a state of cultivation is fit for the operation of the plough, it is necessary to attend to the means of removing those obstructions which, in a greater or less degree, exist in almost every soil.

1. *Obstructions to Tillage.*

The obstructions to the tillage of lands which have not been subjected to the plough, arise chiefly from inequalities of the surface,—from woody or shrubby plants covering it,—from stony masses in the soil,—and from an excess of moisture, proceeding from springs, or from collections of rain-water; and before any successful operation can be attempted, it is necessary that such obstructions be effectually removed. The means of removing the last obstruction have been fully treated of under the chapter on Draining; so that our attention is now to be confined to the consideration of the proper methods of preparing land encumbered with any of the former, and relieving it from such obstacles as either retard or altogether interrupt the necessary operations. It is scarcely necessary to add, that the more perfectly this preliminary work is completed at first, the greater is the saving of labour, and the ultimate advantage, in every step of the future management.

Wood.—Various methods must be adopted in clearing land from wood, according to the nature of the trees to be removed. Large trees of the timber kind must be grubbed up in the proper season of the year. Trees, such as the oak, whose roots penetrate deep in the earth, may be removed by clearing away the earth all round, cutting a few of the stronger lateral roots, and pulling by a rope from the top. But in such trees as have roots shooting laterally along the surface of the ground, these roots must be almost entirely removed before the removal of the tree can be accomplished. Trenching with the spade, and forcing up the roots with the pick-axe, are recommended by some writers as the most effectual means to be pursued in such cases; and by this management, although expensive, the obstructions are not only removed, but the land is advanced in its preparation for future operations. When the roots are of large size, and little decayed, blasting with gunpowder, for which a particular apparatus has been contrived, has frequently answered the purpose. The ashes produced by burning the brushwood, cut and collected on the surface along with the roots, may afford a quantity of useful manure as some compensation for the extraordinary expense. When the larger roots and most of the shrubby plants have been removed, previously to the first ploughing, the ground is sown with such crop as is adapted to the soil and situation; and after that crop is removed, the unfinished operations of clearing the land may be completed by repeated ploughings and harrowings, till the extirpation of every root and plant which obstructs tillage is effected; but when time or expence, or other circumstances admit of it, it is by far the preferable method to complete the clearing process before any crop is attempted to be raised.

In removing the roots of large trees, it has been thought that a good deal of injury is done to the ground by breaking it up and leaving large openings, and by mixing the rich surface-soil with the less fertile and sometimes hurtful under-soil. To remedy these inconveniencies, it has been recommended to allow the roots or stools of different kinds of plants, after their tops are cut off, to remain in the ground and undergo a spontaneous decay, while the larger roots may be taken up some time afterwards, and this with little disturbance of the under-soil, and their places filled up with stones and other useless materials from the surface. When the land is thickly covered with leaves, or other vegetable matters, they may be collected in heaps to decay naturally, or they may be burnt and the ashes spread over the soil. The surface, where it may be necessary, being levelled, and those places which are bare of vegetation, after being superficially harrowed, being sown with the suitable kinds of grass seeds, a second harrowing is given, and then a complete rolling of the whole to admit the scythe. After this preparation, such land is to be stocked with sheep; and, continuing the operations of the scythe when any woody shoots appear, it is to be kept in close pasturage till the smaller roots that were left shall yield to the plough, and then a succession of grain crops may commence.

A portion of lime, or some other calcareous matter, added to the vegetable materials, promotes their decomposition and decay, and produces a quantity of valuable manure, which, being spread on the surface, encourages the growth of the better kinds of herbage. This is more relished by the sheep, is eaten closer, and soon forms a finer sward. By proceeding in this way the expence is not very considerable, where there is a scarcity of fuel, more particularly when the large trees have been properly cut down, and the brushwood cut off a little below the surface. In some cases the larger roots and the stubs of the copse wood are more than sufficient to meet the expence of clearing and levelling the surface.

Shrubby plants.—In clearing land of various kinds of shrubby plants, advantage may be taken of changing the nature and texture of such soils as are peculiarly suitable to their growth. Thus, the different kinds of willows which affect moist places, have their growth interrupted by draining the land; and the improvement of a sandy or gravelly soil, which is favourable to the broom and the bramble, checks the luxuriance of plants of that description. For this purpose the application of clay marl, loamy earth, composts of peat and lime, or other manures, according to the nature of the soil and the object of the change to be effected, is to be regulated. But when such shrubs have attained a considerable size, the usual method is to cut them close to the ground, to dig round the roots, and to grub them up. The practice of burning furze before grubbing up should be avoided, on account of the loss of a large portion of vegetable matter on the surface.

It frequently happens, that lands which have been thickly overrun with brushwood, and particularly with furze and broom, are again infested with the same troublesome plants when under grass, from the seeds and small roots which lurk in the soil; it is recommended to keep such lands under tillage for a sufficient length of time, and, with the aid of lime and other suitable manures, the risk of their recurrence is greatly diminished. But if they are laid down with grass, and pastured with sheep, every shoot, as it appears above the surface, is destroyed, and the ground in a short time is entirely cleared.

Heath.—In preparing ground covered with heath for the operations of tillage, the heath, which is slow in its progress towards decomposition and decay, and affords but a scanty addition to the soil when it is converted to vegetable mould, may either be burnt down in the dry season of spring, particularly when it grows high and close, or it may be pared off with a thin slice of the surface, or cut down with a strong short scythe, collected into heaps and consumed by fire. In whatever way the heath has been removed, a large proportion of quick lime is recommended to be applied to the surface before ploughing, when its effects, according to some writers, are most visible in destroying the remaining roots of heath and coarse herbage, or it may be spread on the ploughed surface.

Paring and burning.—Analagous to one of the processes just mentioned for the reduction of heathy ground, to a state fit for tillage, is that of paring and burning certain lands with the same view. This subject has excited a good deal of diversity of opinion, and even some degree of controversial discussion both among practical and speculative writers; for, while some have extolled its advantages without proper discrimination, others, observing its injurious effects in particular cases, have greatly underrated its benefits when judiciously conducted. After all that has been said and written on the subject, there seems to be little difficulty in forming a correct judgment in what circumstances such a practice may prove beneficial. One of the objects of the process of paring and burning is, to prepare the surface of ground which is covered with shrubby plants and coarse herbage for the purpose of tillage. This object is fully

Arable land.

attained by such means. But this is to be regarded as only the mechanical part of the operation. It is necessary to consider the changes that take place in the combustion of a large proportion of vegetable and earthy matters,—whether something noxious be not removed from the soil, or whether something under a new form be not added to it, which is salutary in promoting healthy vegetation. The earthy matters in the soil exposed to burning, undergo no farther change than being deprived of their moisture, from which probably arises a considerable difference in their texture or consistence; but the whole of the organized matters, which are chiefly of a vegetable nature, are decomposed, their volatile parts are driven off, and the more fixed ingredients only remain. Some of the products of the combustion, although small in quantity, are of a very active quality, and, mixed with the soil, contribute very essentially to its improvement.

As no soil is fertile which is destitute of animal or vegetable matter, it is obvious that any process by which it is deprived of the necessary proportion of that matter must be injurious, in producing sterility. But the destruction of a large proportion of the organised substances in the soil, is the certain consequence of the process of combustion. If, then, it appear that the quantity of vegetable matter is deficient, paring and burning, by which the deficiency becomes greater, ought to be avoided. "All soils, (says Sir Humphry Davy,) that contain too much dead vegetable fibre, and which, consequently, lose from one-third to one-half of their weight by incineration, and all such as contain their earthy constituents in an impalpable state of division, that is, the stiff clays and marls, are improved by burning; but in coarse sands, or rich soils, containing a just mixture of the earths, and in all cases in which the texture is already sufficiently loose, or the organizable matter sufficiently soluble, the process of burning cannot be useful. All poor siliceous sands must be injured by it; and the operation is never performed by good agriculturists upon siliceous sandy soils after they have once been brought into a state of cultivation." The soils adapted for paring and burning are such as contain a redundancy of vegetable matter, some of which, by the process of combustion, is brought into an active state, and serves as a valuable manure in promoting the decomposition of the remaining organised substances, and thus enriches and improves the natural soil, by rendering it less compact, less adhesive, and less retentive of moisture.

It may perhaps be useful to the chemical agriculturist to know the nature of the products obtained by paring and burning; and this may lead to some conclusions with regard to the effects of the process. Specimens of ashes from different soils were examined by Sir Humphry Davy. Two hundred grains, from a chalk soil in Kent, afforded

80 Carbonate of lime.
11 Gypsum.
9 Charcoal.
15 Oxide of iron.
3 Saline matter, sulphate of potash, muriate of magnesia, with a minute portion of potash.

The remainder consisted of alumina and siliceous earth. Some of the ingredients in this specimen of ashes are very active manures. The charcoal was in a state of minute division, and the gypsum and oxide of iron are supposed to produce very powerful effects on soils which contain an excess of carbonate of lime.

The second specimen of ashes was the product of a soil from Leicestershire, in which only four per cent. of carbonate of lime appeared; the quantity of the other earths amounted to three-fourths of light siliceous sand, and about one-fourth of clay. One hundred parts of the ashes yielded

6 Charcoal.
3 Common salt and sulphate of potash, with a trace of potash.
9 Oxide of iron.

The third specimen was from a stiff clay from Cornwall; the land was brought into cultivation from a heath, by burning, ten years before, but having been neglected, the furze plants were springing in different parts of it, so that it required a second paring and burning. One hundred parts of the ashes gave

8 Parts charcoal.
2 Saline matter, chiefly common salt, with a little potash.
7 Oxide of iron.
2 Carbonate of lime.

The remainder of this specimen consisted of alumina and siliceous earth. It is observed, that the quantity of charcoal was greater than in the other cases. The portion of common salt in the ashes of this soil is ascribed to the vicinity of the sea, which is only two miles distant; but common salt was also found in the specimen of ashes from Leicestershire. In the land from which the last specimen of ashes was obtained, there was an excess of dead vegetable fibre, as well as a portion of unprofitable living vegetable matter; and a very essential improvement was the consequence of the burning. In the speculations concerning paring and burning, attempts have been made to explain the effects, by referring to causes of a very obscure nature. Some suppose that clay, during the burning, absorbs nutritive principles from the atmosphere which may be afterwards supplied to plants. According to another writer, carbonic acid, which, in its combination with iron, is injurious to plants, is expelled during the operation of burning. But the whole immediate effects seem more properly to be referred to the diminution of the coherence and tenacity of clay soils, and to the destruction of inert and useless vegetable matter, and the conversion of the ingredients of which it is composed into an active manure.

Lands fit for paring and burning.—All lands which are overrun with furze, broom, brambles, and coarse herbage of any kind, and which have not been before reclaimed from a state of waste, are brought into a state of cultivation, with expedition and certainty, by the process of paring and burning. The same method is successfully practised on boggy, moory, and peaty soils; on mosses containing calcareous matter, either in the soil or subsoil, or a considerable proportion of clay; or such as have been top-dressed with clay; or on a shallow mossy soil, resting on a clay subsoil. An experiment by Mr Young, on a cold, wet, poor loam, with a clay-marl bottom, shews the remarkable effects of paring and burning. An old grass field, of $4\frac{1}{2}$ acres, was the subject of the experiment. Four acres were ploughed four inches deep, which was the whole depth of the soil. Four heaps were formed in the field, and, from particular circumstances, the calcination was supposed to be carried too far, but the ashes were spread and ploughed in with a shallow furrow; turnip seed was sown, and slightly bush-harrowed; the crop was luxuriant, and the produce on the burnt part was double of that on the half acre which was not pared. At the end of three years, when the whole field was in grass, the burnt part of the soil, if any difference existed, appeared the best.

The practice of paring and burning is common on chalky soils in different parts of England, as, on the Cotteswold hills in Gloucestershire, in the sheep-walks and warrens on the Wolds in the East Riding of Yorkshire, in Hampshire and Wiltshire; and in the West Riding of Yorkshire, limestone lands, with only four inches depth of soil have been pared and burnt for ages, without any appearance of that waste or destruction to the soil, which is apprehended by those who think unfavourably of this practice. The same process has been found equally beneficial in Kent, where a great extent of land produces abundant crops of wheat, barley, and oats, after being several times subjected to it. Paring and burning are particularly recommended as the best method of breaking up old, worn out, sainfoin leys; for if the plough be merely had recourse to, the red worm, which is often abundant in leys of this description, is exceedingly destructive to the corn crop. Paring and burning for turnips is considered the safest and most successful husbandry in such cases.

Operation of paring.—Different instruments have been employed for separating the sward from the surface of the soil. When the sod is pared off, the instrument in use in most districts, is the breast spade, or breast plough, or what is called in Scotland the *flaughter* spade. The thickness of the sod cut off is about an inch, or $1\frac{1}{2}$ inch, about one foot broad, and three in length. When the operation is conducted on a large scale, as in the fenny districts on the eastern coast of England, the horse paring plough, which is differently constructed, but varying chiefly in the breadth and sharpness of the share or sock, is an implement well calculated for paring off the sward of level grounds, and such as are free from stones. In the fenny and peaty lands of Cambridgeshire, which are free from stones and large roots, the paring is economically and effectually performed by a particular plough, which turns off a furrow from 12 to 16 and 18 inches in breadth, with little more than an inch in depth; but in some of the western counties, the common plough is used when the sward of old grass fields is to be pared. They are rib or slob furrowed about the beginning of winter; are again cross ploughed the succeeding spring, and the sods are collected and burnt. When the plough is employed in this way, a wing turned up on the furrow-side of the share is added, by which the breadth of the furrow is regulated. Another method, which is practised in Devonshire and Cornwall, for breaking up grass lands, and distinguished by the name of *skirting*, is performed by leaving part of the sward or surface alternately unturned, and upon this the next thin furrow slice is laid, so that the swards of each are brought into contact, by which means the decomposition of the vegetable matter is promoted, and what remains, after cross ploughing and harrowing, is separated from the soil, collected into small heaps, and burnt. This operation is called *beat burning*.

Depth of soil pared.—The nature and thickness of the soil must, in a great measure, regulate the depth or thickness of turf to be separated. A light thin soil ought not to be pared so deep as a stiff heavy soil, covered with a close mat of vegetable matter. The usual depth of paring is from one to three or more inches, while some, who are zealous advocates for this practice, take off turfs, even from thin chalky lands, as thick as the nature of the soil admits, and assert, that the thicker they are the better, if they contain a sufficient quantity of vegetable substance to make them burn well.

Burning.—The operation of burning is differently conducted in different districts. According to some writers, stiff and clayey soils would derive considerable advantage from the fire being brought into contact with the whole surface, while, in soils which are thin and light, the sward pared off is collected and piled up in heaps, to undergo combustion, without permitting the fire to act upon the mould over the whole surface. If the first method be adopted, the sods must be collected into very small heaps, so that they may be burnt upon as great an extent of surface as possible; but, according to the other method, they are formed into small circular heaps, the sods being placed with the grass side downwards, for the admission of air. But, as soon as the combustion has fully commenced, the openings both at the bottom and top should be closed up, that it may proceed in a slow, smothering manner, and the heaps are allowed to extinguish themselves. In paring heaths, downs, moors, and old sainfoin leys, it is recommended that the heaps should not be larger than to yield from 12 to 15 bushels of ashes, otherwise the turfs are apt to be too much burnt; but when the weather is unfavourable, the heaps should be increased in size, to promote the combustion. It should be observed also, that thin sods burn in smaller heaps than those of greater thickness.

If the season be not very wet, the sods are sufficiently dry for burning in about a fortnight or three weeks; but in rainy weather a longer time is required, and they must be turned more than once, to prevent the roots and shoots from striking out, by which the combustion would be interrupted.

When the process of burning is fully completed, and the whole is reduced to the state of ashes and earthy matter, it should be spread on the land as soon as possible, and in as regular and equal a manner as can be effected; and the application of the ashes to the soil should always be made before rain falls, otherwise the saline portion of the ingredients is carried off, and its beneficial effects are lost. It is recommended also, to secure the full influence of the ashes, to give the land a slight ploughing immediately after they are spread.

Season for paring and burning.—Dry weather, it is obvious, is most favourable for this operation. It is most extensively practised in the months of April, May, and June; but the particular period is oftener regulated by the state of the weather, and the nature of the crop which is to follow. In the northern districts, the end of May, or the beginning of June is considered a very convenient season, when green vegetable products are in their most succulent state; but in the southern counties, an earlier period is fixed upon, or the interval between the hay and harvest time is chosen, if the land to be improved be not of great extent. If a large tract of land is to be improved by this operation, the autumn may be the most convenient season for performing it. When barley or oats is to be sown after paring and burning, it is necessary to have the process completed as early in the spring as the weather will admit; but if the crop intended be rape or turnips, the end of May, or the beginning of June, is a proper time; and when it is proposed as a preparation for wheat, the month of July, or the beginning of August, may, in a good season, answer the purpose.

Stones.—Stones which are either in a loose state, or fixed in the soil, form serious obstructions to the cultivation of land. Deep and alluvial soils rarely contain large masses of concealed stones; and, if smaller stones should appear on the surface after harrowing, and particularly when the land is to be laid down with grass to be cut for hay, they should be picked off by the hand, before the application of the roller, or they may be forced into the soil by means of heavy rolling; but when the stones are collected, they should not be thrown into heaps in the furrows, but completely removed, otherwise they may be again dispersed over the ground. This work can be most conveniently and effectually done when the land is under summer tillage. When the soil is wet, the stones may be collected into heaps, and removed during the first opportunity of a dry season. The removal of small stones from certain lands, has been supposed to be injurious to the crop, from depriving the plants of shelter in the early stages of their growth, or from some change in the power of absorbing or giving out heat or moisture; but perhaps a closer investigation would discover that the diminution of fertility might be traced to some other cause.

When the stones are of a large size, and fixed firm in the ground, or are *sit-fasts*, as they are called in some districts, and when they appear above the surface, it is recommended as the best practice, to dig them completely out of the earth, after they have been blown to pieces by means of gunpowder. This latter expence may be saved when they are of smaller size, by digging round, splitting them with wedges, or breaking them with large hammers. Stones are sometimes removed from the surface, by sinking large pits, but as the stone is entirely lost, and the business cannot be conducted without danger to the workmen, this method should only be had recourse to when others are impracticable.

When the stones are concealed below the surface, their situation must be discovered, either by forcing a sharp instrument into the ground, or by marking the spot where the plough is obstructed; but if the stones are very numerous, and the price of labour low, the use of the spade, in preference to the plough, is recommended as the most economical method of preparing such land. In whatever way the land is cleared, the whole business should be completed before the operations of tillage commence, because the loss by the destruction of the implements, and the unavoidable delay from such obstructions, more than counter-balance the necessary labour and expence in removing them.

The expence of clearing land from stones may be diminished by applying them to various useful purposes, as in the construction and filling up of hollow drains, or in building walls for fences, or some of the farm-offices; and it has been stated, that in situations where any useful application can be made of large surface stones, the most rugged lands may be profitably reclaimed.

In preparing land for the operation of the plough, it is scarcely necessary to add, that the surface should in all other respects be so adjusted, by filling up hollow places, and reducing every kind of inequality, that it shall meet with no obstruction in its progress. In some cases, advantage may be taken of the stones, or other useless and rugged materials, by collecting and throwing them into hollow spots, and covering them to a sufficient depth with good soil.

Sect. II. *Ordinary Tillage.*

After the obstructions which have been noticed are removed, the soil is turned up and loosened for the reception of the seed. But before the operation of the plough, which is the implement in universal use for this purpose, is admitted, it is of no small importance to consider the soil, the season of the year, and the nature of the crop proposed. It is a prevalent opinion, that there are few soils which are not improved by ploughing about the end of autumn or beginning of winter; because it is supposed they absorb and retain a large proportion of moisture for the approaching summer; but when they are turned up in the spring or summer months, the rapid evaporation which follows occasions an excessive waste of moisture, and renders the land too dry. It is supposed, too, that the soil exposed during the winter season becomes mellow, as it is expressed, and derives some beneficial influence from the atmosphere. But before any decided opinion can be formed of the advantages of this practice, it would be necessary to inquire what is precisely understood by *mellowing* of the soil, and *atmospherical influence*, phrases which are in frequent use among agricultural writers—what are the changes which are thus induced,—what is absorbed by the soil,—and what is extracted from it during this exposure. The exposure of the water, by freezing in winter, tends to reduce stiff adhesive soils to a friable state; and this, although somewhat of a mechanical nature, is undoubtedly a considerable benefit.

The peculiar condition of the soil ought also to be considered before any operation of tillage is attempted. No land, of whatever description, should be ploughed when it is loaded with wetness. Tenacious soils when subjected to the operation of the plough in such a condition, are apt to cake and run together in lumps, which it is afterwards difficult to reduce and pulverize; and besides the additional labour which is necessary, the ground is greatly injured by *poaching*, or the treading of the feet of the cattle. Marshy or mossy soils which have been brought into cultivation, can rarely admit the plough when in a wet state; so that such soils can only be advantageously wrought during dry weather. An intermediate condition of the soil, which is neither too wet nor too dry, which is neither so tenacious as to adhere to the horses feet, or to the implements employed in the tillage processes, nor so friable as to fall into the state of loose earth when it is turned up, is the most suitable for the successful and perfect operation of the plough. But when the nature of the crop requires it. the precise regulations of times and seasons cannot be always rigidly observed.

Operation of ploughing.—By the peculiar construction of the plough, which has the mould-board on the right side, the mass of soil, or the furrow-slice, is turned over during its operation to the same side. In this description, which refers to the plough drawn by two horses, the horse on the right side, or the off-side horse, walks in the furrow, or the space which is left vacant by the removal of the former plit. The near-side horse, or the horse on the left hand, walks on the fast land, and the ploughman walks in the new furrow, or the space which is left by the furrow-slice just formed. In careful ploughing, no part of the land should be left unturned up, and the furrow-slice should not be permitted to fall back into the furrow, which sometimes happens when the breadth of the slice is too great, or when the left handle of the plough is too much depressed. To prevent this, the ploughman who is attentive to perform his work neatly, walks with his left foot only in the furrow, while he presses down with the right foot the newly formed furrow-slice. This management is peculiarly requisite in ploughing old leys, and especially in striking the ridges.

Breadth of the furrow-slice, &c.—The breadth, as well as the depth of the furrow slice, is regulated at pleasure, by varying the draught on the bridle of the plough. When a broad slice is wanted, the line of draught of the plough is directed to the left or land side, and when a greater depth is required the plough goes deeper; but the regulation of the plough is so managed, that if merely kept in its working position, it cuts a little broader and deeper than what is wished. The coulter also has a slight inclination towards the left side, and the point of the sock is somewhat directed downwards. This arrangement of the different parts is called in Scotland the *tempering* or *setting* of the irons. The dexterity of the ploughman consists in making his horses move in a straight line, and in keeping the plough in the same uniform direction. Artful ploughmen, to save themselves attention and labour in performing their work, give the plough too great a tendency to dip into the ground, and this they counteract by pressing with their own weight on the handles, at the expence of unnecessary additional labour to the horses.

The furrow slice is turned over to a greater or less degree, according to the proportion between the breadth and depth. When the breadth and depth are nearly equal, the furrow-slice turns over at an angle of about 45°; and a field ploughed in this manner presents the appearance of angular drills or ridgelets. When the breadth of the slice much exceeds the depth, it is almost entirely turned over, with its former surface downwards, and each successive slice somewhat overlaps the preceding; but when the depth is much greater than the breadth, the slice falls over on its side, and is somewhat overlapped by the next, leaving the original surface bare, and slightly inclining to the horizon. The nature and condition of the land determine the preference to be given to each of these modes of ploughing. The square slice is considered best adapted for laying up stubble land after harvest, to be exposed during the winter, as a preparation for fallow or turnips. The shallow slice, with considerable breadth, is convenient for breaking up old leys, because it covers up the grass turf, and the fertile soil is not buried too deep. The method of ploughing, by making the depth exceed the breadth of the furrow-slice, is not approved of.

In determining the depth of the furrow in ploughing land, the quality of the soil, and the kind of crop to be cultivated, are to be considered. Some shallow soils, which are extremely fertile, rest on a subsoil which is injurious to vegetation. In such cases, deep ploughing would be highly improper; but, on the other hand, when the subsoil contains ingredients, such as calcareous or vegetable matter, which serve to increase the fertility of the soil, it may be useful to the crop to have a portion of it occasionally turned up by the plough. Mr Young recommends that one deep ploughing, when the soil admits of it, should be given in the course of 12, 18, or 24 months; and when this is completed, shallow tillage, by the operation of implements which merely stir the surface, is a better practice than working deeper; but, in general, for ordinary corn and grass crops, no great depth of furrow is required; nor is deep ploughing necessary even for cleaning land; since it is found that a clean, shallow ploughing, or hand-hoeing, is the most effectual method of destroying weeds. From four to six or eight inches may be considered as a sufficient depth of furrow in ordinary cases.

For certain crops, such as carrots, a deep ploughing is requisite. In soils which admit this kind of crop, what is called *trench*-ploughing, is practised. This is executed by means of two ploughs, which follow each other in the same furrow; and the second plough throws its furrow-slice on the top of the first. The first plough goes to the depth of seven or eight inches, and the second increases the depth four or five inches more, so that a furrow of 12 or 13 inches deep is formed in this way. According to the views of some agriculturists, deep ploughing is beneficial, by bringing up a portion of fresh soil, which promotes the growth and increases the quantity of different crops, such as clover, turnips, beans, and potatoes. It is also considered as of no small importance in obviating the effects of too wet or too dry a season. The ground is more effectually cleared of weeds by the same means; animal and vege-

Arable land.

table manures are supposed to be more useful by being well covered up, and the staple of the soil is increased, so that the roots of the crop are less liable to be injured by wetness, and can resist longer the effects of drought.

Ridges.—In ploughing a field, the furrow-slices are arranged into beds of different breadths, which are denominated ridges, or lands, and they are divided from each other by open furrows. By this arrangement, the future operations, as the regular application of manure, the equal distribution of the seed, and the cutting down of the crop, are conducted with greater facility and uniformity. The furrows which form the divisions of the ridges are necessary, in strong and retentive soils, for carrying off surface water; and hence they are sometimes called *water-furrows.*

Direction of the ridges.—As far as the situation of a field admits of it, the direction of ridges should be north and south. Deviations from this position, for the purpose of draining the land, or on account of the particular form of the inclosure, may be often necessary; but it seems always advantageous to bring the course of the ridges as nearly in this direction as possible; for it appears, that in ridges which have an east and west direction, even when the elevation is not considerable, the crop on the south side has ripened a week earlier than that on the north; and at the time of reaping, the wheat has been observed too ripe on the south side, while, in many spots, it was green on the north. On ridges which have a north and south direction, the ripening and drying of the grain, after it is cut down, are more uniformly accomplished, because the shocks are more fully exposed to the influence of the sun and wind.

Breadth of the ridges.—Great diversity of opinion and practice prevails with regard to the breadth of ridges; and it has been observed that the breadth and flatness of ridges should be increased, as the soil is more of a light sandy quality; while, on the other hand, they should be narrower, higher, and of a more rounded form, on a stiff clay soil, that the redundant water may be freely discharged. In loamy soils, the ridges are recommended to be broad and flat, or narrow and round, according as they approach to the sandy or clayey soils. Broad ridges, or even, in some cases, altogether flat, without any furrow, are formed on soils of a sandy nature, that the moisture, which is apt to pass off too rapidly, may be more effectually retained.

In wet, clayey, or stiff and adhesive loamy soils, with a sub-soil of clay, narrow ridges are recommended, to preserve the crop from excessive moisture. In such soils, a ridge of three or four feet is considered fully sufficient; and in Essex, a ridge of three feet in breadth is found to answer the purpose effectually, and is preferred to ridges of greater breadth, for allowing the water to pass off without washing the land. In some of the best cultivated districts of Scotland, the ordinary breadth of ridges is 15 or 18 feet. On thin clays, with a retentive bottom, some agriculturists prefer a ridge of nine feet, as most convenient for removing the excess of moisture; while others think that a ridge of 18 feet carries off the water as effectually as the narrow ridges which are adopted in some parts of England. On dry turnip soils, with an open sub-soil, the land is formed into ridges of double the breadth, as 30 or 36 feet; and in completing the tillage operations on a soil of this description, especially before it is laid down for grass, it is usual to cut up a narrow ridgelet, or single-bout drill, between the broad ridges, to direct the process of sowing; and when the seed is covered in by the harrow, all the ridgelets are nearly destroyed, so that the field presents a smooth, uniform surface.

Arable land.

Forming ridges.—When a field is to be formed into ridges, the ploughman to whom this work is entrusted is furnished with three or more poles, shod with iron, and each $7\frac{1}{2}$ feet long, when the breadth of the ridges is determined to be 15 feet. The head ridges, on which the horses and plough are turned, are first formed, and a breadth of 18 feet is the least to afford convenient space for this purpose. The intended breadth of the head land is measured off with the poles, at right angles to the boundary of that end of the field, or at right angles to a straight furrow drawn by the plough, when the boundary itself is irregular. The breadth of one head ridge being measured off, and three poles at least set up in a straight line, a furrow is drawn in the line of the poles, from one side of the field to the other, and the plough is returned in the same furrow to correct any inequality. The limits of the other head-ridges are laid off in the same way. One straight side of the field being assumed as the direction in which the ridges are to run, the ploughman measures off one length of a pole from that side, either at the top or bottom of the field; and at right angles to this straight side he sets up one of the poles at the point where the plough is to enter; a second pole is fixed in the same manner, at such a distance in advance as to be distinctly seen, and a third at the intended termination of the ridge. All the three poles are in one straight line; and sometimes, from the great length or inequalities of the field, a greater number than three poles is required. The plough is entered at the first pole, and the line of poles being kept precisely between the horses, the furrow-slice is formed; and when the first pole is ploughed down, the horses are halted, and two lengths of the pole are measured off for the middle of the second ridge. When the second pole is ploughed down, two lengths are measured off in the same way; and the plough having reached the extremity of the field, the last pole is set up in the same line with the two former, and all the three poles are in the line of the crown of the second ridge. To insure the correct execution of these operations, it is necessary to draw three cross furrows at right angles, otherwise there is some danger that the breadth of the ridge may not be exactly the same at the different extremities. This operation is called *striking furrows* in England, and *feiring* in Scotland.

After the first furrow-slice is formed through the length of the field, some ploughmen return in the same track, and throw a furrow on the other side, that there may be no firm land left below, and then the two sides are thrown back to form the crown of the ridge. But it is more usual to turn the plough short to the right, and to draw a second slice directly to meet or overlap the first, while any inequalities which have been occasioned by the irregular motion of the horses, in drawing the first slice, are corrected. The ploughman next proceeds to the second line of poles, and repeats the same series of operations till the whole field is worked off. When other ploughmen are employed, they fall in successively as the first has marked out the proper spaces, and all the slices are turned inwards or towards the crown of the ridge.

Another method, which answers less dexterous ploughmen, is sometimes practised for the purpose of marking off ridges. A strong pole, whose length is exactly equal to the breadth of the intended ridge, is attached to the plough at right angles to the line of draught. One end is placed across the stilts, exactly opposite to the coulter, when the other end projects towards the left hand of the ploughman, and is retained in its place by means of a rope, extending from the outer extremity of the pole to the collar of the near-side horse. A coulter, or harrow-tooth, is fixed in a perpendicular position, at the outer end of the pole, and as the plough moves forward, it makes a mark on the ground, parallel to the line of draught. By this contrivance, while the plough is going along the crown of one ridge, the marker traces the line upon which the furrow of the next ridge is to be drawn.

In consequence of inequalities in different parts of the same field, it is sometimes necessary to change the direction of the ridges, for the convenience of discharging surface water. When such deviations are required, an oblique furrow, either quite straight or waving, is drawn at the place where the change of direction is made; and at this oblique furrow all the ridges of the original direction terminate, and from it a new series of ridges commences, which is marked off in the same way as if it were a new field. The new oblique furrow is either made the crown of a ridge or a water-furrow, according to circumstances; and the oblique ridges thus formed are denominated *butts*.

Steep land.—In ploughing steep land, the ridges should be drawn in an easy sloping direction, that the water may be allowed to pass off in a gradual manner. In this way, there is not only advantage in the economy of labour, but the injury and inconvenience of heavy rains washing down the soil are in a great measure obviated. In such cases, the ridges of steep lands are neither to be formed parallel to the declivity, nor at right angles, but in a diagonal direction, in which the slope shall be such that the furrow-slice falls easily away from the mould-board, both in ascending and descending the field. This mode of directing the ridges on steep land, has another advantage,—that cross ploughing, when such is required, is readily accomplished by reversing the diagonal. When extremely steep land is brought under tillage, the ploughing must be conducted directly across the hill, and all the furrow-slices are turned downwards. When this work is performed with the ordinary plough, it must be carried back empty in the open furrow; but time may be saved and a great waste of labour avoided, by employing a turn-wrest plough, in which the mould-board shifts to either side. In ploughing a hill of a conical form, it is recommended to begin at the bottom, and, with the left hand always to the hill, to go round in a spiral direction. By this method of proceeding, any number of ploughs may work at the same time, with this precaution, that the lowest, which enters first, shall always keep in advance, all the rest succeeding each other in regular order.

Different kinds of ridges.—Various methods are practised in forming ridges. On dry soils, the furrow-slices of each ridge are all turned in the same direction, while those of the contiguous ridges are laid the contrary way. This is called *casting*. Sometimes the ridges are split out, so that the crown of the old ridge becomes the furrow of the new one. This method of ploughing is denominated *ridge* and *furrow*, and in Scotland *crown* and *fur*. On all strong soils the ridges are necessarily formed by twice gathering all the furrow-slices inwards, in the direction of the crown; and in this case the ridges and furrows retain their original situation; but when these double gathered ridges are broken up for summer fallow, it is usual to split or cleave them down, by reversing the former operation, and turning all the furrow-slices outwards, beginning at the furrows and ending at the crowns. In this way the ridges are reduced to half of their original breadth. The practice of ribbing, or rice-baulking, which is now rarely followed, was a kind of half-ploughing, in which the land intended for barley the succeeding year was thrown up after harvest into one bout of ridgelets or drills, a slip of fast-land being left unploughed between the furrow-slices, which were turned over to cover it.

Crown ridges.—Broad, high, and irregular ridges, which were at one time common, are now rarely met with, where improved cultivation has been adopted, excepting in stiff, wet soils, with a retentive sub-soil. On soils of this description, and in thin, weak clays, some danger may probably arise from reducing high crooked ridges to straight lands of moderate breadth and height; but in all fertile soils of sufficient depth, no doubt can be entertained of the convenience and profit to be derived from such improvement. The elevated crown, unequal breadth, and crooked direction of ridges, which formerly prevailed in some of the most fertile and populous districts of the country, seem to have had their origin, according to Mr Donaldson, in the manner in which lands were cultivated in the open field or run-ridge state. The small portion of land held by each tenant, precluded any attempt at proper draining; the furrows, which were the boundaries of each possession, were also the drains for carrying off the water, and the ridges were raised high in the middle, to secure the crop from wetness. The ridges are observed to be broader at one extremity than at the other. The narrowest end is usually the wettest; and it is supposed that the breadth was purposely diminished, that the furrows, the only drains which existed, might have the greater effect in drying the land. As the most crooked ridges are on the steepest and most sloping grounds, the same writer presumes, that this deviation from a straight course was adopted to prevent the soil from being washed down in heavy rains. But the original formation of the ancient crooked ridges, which are observed to have the curvatures at the extremities invariably reversed, is accounted for in a different way by others. As the old plough was itself of great length, and as it was drawn by three or four pairs of oxen, and even at this day, in some parts of England, by six horses following each other in a line; if the ridges had been drawn in a straight direction through their whole length, the unwieldy implement, and the numerous team, could only be turned on a very broad head ridge. To obviate this difficulty, the team moved in a curved direction at both ends of the ridge, that the plough might be drawn out on a head ridge of moderate dimensions; and as the ridges were gathered into high crowns, sometimes to a great height, the inclination to the left and the turning to the right, after the plough was drawn obliquely out on the head-ridge, answered the ploughman's purpose much better than if the deflection had been to the right, in which case it would have been necessary to drag back the plough to make it enter at the proper place, —a task to which the strength of one individual was altogether unequal, especially with the heavy and cumbersome implements then in use.

Levelling ridges.—The operation of bringing elevated, curved, and unequal ridges into a more level, regular, and straighter form, is attended with some difficulty. When this work is performed by the plough, the best time for executing it is when the land is under summer fallow, and is then subject to a course of repeated ploughings. When the elevation of the ridges is not very great, they are readily brought into proper form, by splitting or cleaving them down in the middle. The plough enters at the old furrows, and terminates at the crown of the former ridge; so that the former furrows become the crowns of the new ridges, and the new furrows are drawn in the middle of the old ridges. In open, light, or gravelly soils, the plough may be successfully employed in levelling the ridges, without any bad effects to the future crop; although, in soils of this nature, as well as in every other, the precaution of avoiding the risk of turning up too much of the sub-soil, when it contains useless or hurtful ingredients, should be strictly observed.

To preserve the vegetable surface-mould, and to avoid the injury that may arise from bringing up any of the under-soil, the following method of levelling ridges, by means of the spade, is recommended by Dr Anderson: A furrow is drawn with a plough across the ridges of the whole field to be levelled. This furrow is divided into as many parts as there are workmen; and each having a ridge or two allotted to him, as soon as the plough passes his division, begins to dig in the bottom of the furrow which the plough has just made, about the middle of the old ridge, and keeping his face to the old furrow, works backwards till he come to the middle of the old ridge, and goes deeper as he proceeds, according to the height of the ridge to be reduced. Turning towards the other furrow, he repeats the same operation on the other side of the ridge, so that the bottom of the trench thus formed may be as nearly level as can be conveniently made. That part of the furrow allotted to him, which is made by the plough in going, being finished, he proceeds to finish in the same way his own portion of the furrow which is formed by the returning plough. In levelling ridges in this way, it ought to be recollected, that allowance should be made for the subsidence of the loose earth, and therefore the old furrows ought to be raised higher than the middle of the old ridges. These temporary, or cross ridges, are recommended to be made forty or fifty yards broad; for although some time is lost in turning at the ends of the broad ridges, the advantage of few open furrows overbalances this loss; and, to keep down the height in the middle of each of these great ridges, it may be proper to draw the furrow which is to be the middle of each some time before the operation of levelling with the spade commences, that all confusion or loss of labour may be prevented. This breadth of ridge is convenient where the land is in a sufficiently dry condition; but in wet stiff soils it must be greatly diminished. From a comparative estimate of the expense of levelling by the spade and by the plough, it appears that it can be accomplished at one-fourth of the expense by the former method.

Another method of levelling ridges is described in the Report of the State of Agriculture in the county of Perth. The good soil on the crown of the ridge is removed to one side by two or three ploughings in the same direction, and turning the furrow always the same way. A sufficient quantity of the buried soil is then thrown with the spade from the crown of the ridge to fill up the old furrows, and the good soil is equally spread over the whole surface. Should it be thought necessary to save the soil over the whole ridge, one side may be taken first, and then the same operation may be repeated on the other. A summer fallow, with a copious application of lime to the new soil, completely restores its powers of fertility. For the purpose of levelling the uneven surface of land, a machine which, it is said, effectually answers the purpose, has been invented by Mr Charles of West-Mead, Langhorne, in Carmarthenshire, a description of which is given in the 21st Volume of the Transactions of the Society of Arts. Whatever method is followed, it is of no small importance to have the ground reduced at once to that degree of smoothness of surface which renders every future tillage operation convenient and efficient. But in lands whose surface has been so much changed, its firmness is for some time very unequal. It may be therefore necessary to lay it into narrow ridges for some years after such operations, and to keep the furrows quite clear, to prevent the stagnation of the water among the loose earth with which the old furrows were filled. *Two bout* ridges, as they are denominated, when the condition of the soil and the situation of the land admits of their formation, are the most suitable for this purpose.

Extent ploughed in a day.—As agricultural labour of every description in which men and horses are employed, is always attended with a heavy expense, it is then of consequence to be able to determine the quantity of work which can be performed, without imposing too severe a task on the labourers, but particularly without oppressing the horses by excessive exertion. In ploughing, the quantity of land which can be turned up in a day, with one man and a pair of horses, and with the improved implement which is generally used in Scotland, must depend on the tenacity and condition of the soil,—the breadth and depth of the furrow-slice,—and the strength and vigour of the horses. In Scotland, to which the estimate now made refers, the period of a day's work on heavy soils extends to about nine hours—five hours in the morning and four in the evening, with an interval of two hours for rest; but when the soil is of a lighter nature, the horses are wrought ten hours. An English statute acre is 220 yards long and 22 yards broad; and if the acre be ploughed in regular slices of nine inches each in breadth, it will be divided into 88 furrow-slices, of 220 yards each in length, so that the whole series of slices extends to 19,360 yards; and if 12 yards be added to each of these slices for the ground travelled over by the plough in turning, the whole work of one acre extends to 20,416 yards, or 11 miles and nearly five furlongs. In the stiffest lands where ploughing is admissible, and the chief obstructions to tillage have been removed, a pair of strong horses, in good condition, ought to plough three-fourths of an acre in a day's work of nine hours. In the succeeding ploughing of a summer-fallow, even at the full depth, one acre may be easily executed in a day; and when the land is in fine tilth, in giving the seed furrow with a shallow slice of about four inches, $1\frac{1}{4}$ acre may be accomplished. During the short days in winter the horses are rarely employed longer than six hours, during which about half an acre may be easily ploughed. Hence it appears, that, in ordinary circumstances, an acre may be regarded as a full average for a day's work throughout the year.

In estimating the expence of ploughing, it is stated, that one efficient farm draught, consisting of a ploughman and a pair of good horses, cannot be kept up at less than L.115, on the average, per annum; and proceeding on the supposition that this draught is employed through the whole year, excepting the days on which no work is executed, the average expence of ploughing an acre of land appears not to be less than 8s. 6d.; and, in many cases, the real expence exceeds that sum. This estimate also refers to the improved method of ploughing in Scotland; and comparing it with the practice still followed in many parts of England, where the expence of ploughing the land with a four-horse team, supposing wages and horse-keeping to be the same in both countries, is stated at no less than 17s. or double the expence at which the same work is executed in Scotland, and with six horses not less than L.1, 4s. the advantage in point of economy is obviously in favour of the Scotch method. The simplicity, however, and economy of the improved plough, and the dexterity and accuracy with which it can be managed, give it a decided preference over the heavy, cumbrous, and often inefficient implements, which require great expence and power of draught to put them in motion.

Scarifying, &c.—For the purpose of saving the labour and expense of working land with the plough, after it has been subjected to its operation, as after a ploughing in autumn to prepare the soil for receiving the seed in spring, various implements have been invented, for stirring the surface, without exposing much fresh soil to the atmosphere. These instruments have been distinguished, from their mode of operation, by the names of *scarifier*, *scuffler*, *cultivator*, and *grubber*, under the last of which an implement of an improved construction has been introduced into Scotland. A description of this implement, with the method of using it, and its advantages, have been already given in the preceding chapter. A scuffler, wrought by two horses, is capable of loosening the surface of four acres in a day, and, if the soil be in good condition, even to the extent of six acres. The expence, therefore, of scuffling or scarifying an acre of land, may be estimated at from one-fourth to one-sixth of the expence of ploughing.

Harrowing, &c.—The operation of harrowing is an essential part of the labour of tillage. Harrows are employed for different purposes, as the heavy brake harrow, which is drawn by two horses, and is used for reducing strong land, or where the soil is full of the roots of weeds. The common harrow, which is drawn by a single horse, and is employed in covering the seed, and a lighter description of harrow, is in use for covering in grass seeds among grain which has already appeared above ground. The improved mode of harrowing is practised nearly in the same manner as ploughing. A man or a boy leads or drives, with long whip reins, two or three horses, each of which drags an ordinary harrow. The preferable mode of driving is with whip reins, because, in leading young and restive horses, which are frequently employed in this work, before they are fully trained, the person who leads is sometimes exposed to danger; but the driver, who is behind the harrows, is always at hand to remove obstructions from weeds, clods, or stones, among the tines, or by the harrows riding on each other. Three harrows to one driver are considered as the most economical method of conducting this kind of labour, for they cover a ridge of 18 feet in breadth at twice. In Scotland the operation of harrowing is distinguished by the expression *single time*, *double time*, and *double double*, as the ground is gone over once, twice, or four times; and as it is the usual practice to overlap each of these successively at their edges, they are then called *close single*, *close double*, &c. Harrowing is said to be *end-long* when the harrows are conducted in the direction of the ridges, and *cross-harrowing* when they proceed transversely. It is the usual practice to complete the operations of the harrow in the direction of the ridges; but some agriculturists finish off a field by cross harrowing, particularly in stiff land, under the supposition that the surface water passes off more easily from the crown of the ridge to the furrow.

Rolling.—The roller, of which different kinds have been described, is a useful implement in facilitating the labour of tillage, as in reducing turnip soil, land which is intended for potatoes, or under fallow, into good condition, or fine tilth, to admit the harrows to eradicate couch-grass, and other troublesome weeds, and to break the surface-clods on land sown with beans or barley. For these different purposes, rollers of different weights are employed, and the operation

Arable land.

is best executed across the direction of the ridges, that every part may have the full benefit of the pressure.

2. *Fallowing of Land.*

Beside the usual tillage processes which are performed in the close of autumn, during the mild weather of winter, or in the early months of spring, for the crops of the succeeding summer, certain conditions of the soil demand a more lengthened series of operations in the preparation of land for profitable cultivation. An extended period of dry weather, and the season of vegetation, are essentially requisite for the success and perfection of this extraordinary kind of tillage; and as these requisites only exist during the summer, the operations now alluded to are usually denominated *summer fallowing*.

A vague notion seems to have prevailed, and is perhaps not altogether banished from the minds of some speculative writers, that the exhausted soil requires some time for repose, to recover its wasted fertility, and hence the origin of *fallow*, or a period of rest, during which it produces no crop. No subject has excited more controversial discussion, both among speculative and practical agriculturists, than summer fallowing. Some assert, that under good management, and a proper succession of crops, it is rarely and scarcely at all necessary for most kinds of lands; while others, with equal confidence, maintain, that summer fallowing forms an essential part of a system of good husbandry, and on certain kinds of soil is altogether indispensible.

In considering the necessity and advantages of summer fallowing, it is necessary to take into view the nature of the climate, the quality of the soil, and the kind and value of the crops which are cultivated for a series of years. In certain climates, where the fall of rain is irregular or excessive, the season of field labour is greatly interrupted or extended, and in consequence of these interruptions it is often very imperfectly executed. But if, in addition to these inconveniences from the weather, the soil be wet and adhesive, the difficulty of executing completely the operations of tillage is much increased. Soils of this description, which are hurriedly or imperfectly wrought, in a short time throw up a luxuriant crop of weeds, which at last destroy or greatly diminish the cultivated crops. The ordinary method of raising corn crops, and especially when the tillage processes, from negligence or necessity, have been ill performed, does not admit of any effectual means of clearing land from weeds; and if the soil be unfit for the growth of such crops as can be managed by the drill husbandry, no remedy is left but recourse to a summer fallow, by which it may be restored to a proper condition for profitable culture.

Advantages of summer fallow.—The object of the extraordinary tillage which is pursued when land is under a clean or summer fallow, is to clear it from weeds, and to reduce it to that texture and consistence which are necessary to healthy vegetation. The more zealous advocates of this practice, although with seeming reluctance, admit that by proper management it may be restricted to soils of a clayey nature and a stiff tenacious quality. Such soils are apt to retain a super-abundance of moisture, and under an unfavourable climate are unsusceptible, either in spring or the latter period of autumn, of perfect preparation for the reception of the seed and the growth of the crop. The effects of the deficient tillage of one season are in some degree continued to the next; the soil, which becomes hard and adhesive, is overgrown with weeds; and every crop which is attempted to be raised is diminished in quantity and injured in quality. To complete the tillage processes on soils of this description may be regarded as the chief object of summer fallowing, at least in the view of those who have treated the subject on distinct and rational principles.

Arable land.

The advantages of summer fallowing are obvious in reducing soils which are wet, stiff, and adhesive, and especially those of a clayey nature, to the necessary degree of friability and minuteness of division, which not only admit the manure to be intimately blended and incorporated, but also absorb and retain a sufficient quantity of moisture, and allow the fine fibres of the roots to push out, and extend themselves with facility in search of nourishment. The destruction of weeds is another advantage which is derived from the same practice. The imperfect tillage which the state of the weather and the nature of the soil allow of being accomplished within the ordinary season allotted to that work, tends to encourage and promote the growth of noxious plants, and thus renders the extended operations of summer fallow indispensible for cleaning the soil.

It is supposed, too, that some advantage is obtained by repeated ploughing, and reducing the soil, in consequence of its exposure to the atmospheric air, which combines with the fine particles, and furnishes a larger proportion of oxygen, which latter uniting with the carbonaceous matter, produces carbonic acid, and in this way contributes to the vigorous growth of vegetables. According to the same hypothetical reasoning, the water which is absorbed by a pulverised soil is subjected to the process of decomposition, and its hydrogen uniting with the azote of the atmospheric air, forms ammonia, or volatile alkali, while another portion of oxygen combining with part of the azote, furnishes nitric acid, which, in combination with its base, potash, yields nitre; and these new compounds contribute to the improvement and fertility of the soil. Certain changes of temperature, which no doubt take place, wherever any decomposition, or change in the constituent parts of bodies is effected, are also supposed to be beneficial, either immediately or indirectly, in promoting the growth of plants.

Objections to summer fallowing.—But, on the other hand, there is some reason to suspect, as has been stated by Sir Humphry Davy, that the benefits derived from fallow have been over-rated; and although he admits that it is a necessary practice in lands overgrown with weeds, and particularly such as cannot be pared and burnt with advantage, yet it is unprofitable as part of a general system of husbandry. He rejects the doctrine, that certain principles necessary to fertility, are derived from the atmosphere, and supplied, during the repose of the land, and its

Arable land.

exposure to the air, to the pulverised soil, as well as the old opinion of the effects of nitrous salts in vegetation. By the decomposition of the weeds which are buried in the soil, a certain quantity of soluble matter is furnished; but it may be doubted whether the quantity of useful manure in the soil at the end of a clean fallow, be equal to what it contained when the operations commenced. By the action of the vegetable matter upon the oxygen of the atmosphere, carbonic acid gas is formed, but the greater part of it is dissipated and lost to the soil. The rapidity of the decomposition of the matters in the soil is greatly promoted, and the volatile fluid matters are exhaled by the influence of the sun; and, at the very time when a large portion of nutritious substance is produced, there are no useful vegetables to derive any benefit from it. When the land is unoccupied in the preparation of food for animals, it is suggested, that it should be applied to the purpose of preparing manure for plants. This object is accomplished by means of green crops, in consequence of the absorption of carbonaceous matter, which is supposed to take place in the carbonic acid of the atmosphere. But during a summer fallow no vegetables are raised, either as food for animals, or as nourishment for the succeeding crop. Even the texture of the soil is less improved than during its exposure in winter, when the freezing of the moisture it contains has the effect of reducing and pulverising it. In the drill-husbandry, the land is preserved clean by the extirpation of the weeds by the hand, and manure is supplied, either by the green crops themselves, or from the dung of the animals which feed upon them. It is the peculiar advantage of the convertible system of cultivation, that the whole of the manure is employed, and those parts of it which are less fitted for one crop are suitable for the nourishment of another. Thus, the recent manure applied to a turnip crop, affords a sufficient quantity of soluble matter for its nourishment. The succeeding crop of barley, with grass-seeds, derives from the soil, which is little exhausted, abundant nourishment from the decomposing manure, while the rye-grass and clover remain, which draw only a small part of their organized matter from the soil, and, it is supposed, consume the gypsum in the manure, which is useless to other crops. The grass and clover plants are supposed to draw a large portion of their nourishment from the atmosphere, and their roots and leaves, when ploughed down at the end of two years, and decomposed in the soil, yield manure to the succeeding wheat crop. At this period of the course, the farm-yard manure, which contains phosphate of lime and other matters of difficult solubility, is broken down; and as soon as the most exhausting crop is raised, the application of recent manure is repeated. Such are the speculations of Sir Humphry Davy on Mr Coke's system of cropping independent of summer fallow.

Pursuing a similar plan, Mr Gregg, in his system of cultivation on strong clay soil, an account of which is published in the Transactions of the Board of Agriculture, retains the ground two years in grass after barley, takes a crop of pease and beans on the ley, and ploughs down the stubble for wheat. In some cases the wheat crop is followed by winter tares and winter barley, which are eaten off in the spring, before the land is prepared and sown with turnips. But in stating this method of cropping, as the means of avoiding summer fallow, and as an objection to the practice, it cannot escape observation, that the soil alluded to, although denominated a strong clay, is adapted to turnip culture, and therefore cannot come within the description of those soils which are unfit for the growth of such crops, or those of a similar nature, which might preclude the necessity of fallow.

Arable land.

Were it possible to devise any method of cropping by which the produce, fertility, and good condition of the soil could be kept up, without the intervention of a summer fallow, which is always, in the first instance, attended with the loss of a crop, the saving would be, undoubtedly, immense. In allusion to this circumstance, Mr Middleton, in his Report of the State of Agriculture in Middlesex, when speaking of the advantages to be derived from a proper succession of crops, observes, that "the aggregate benefits to be derived to the country from this measure are not to be estimated; but among the first of these will stand the abolition of fallows, and the introduction of green crops to supply their place, over an extent of about three millions of acres of arable land, which have hitherto, under the fallow system, produced nothing useful during the fallow year. So far as tares and turnips, or potatoes or pease, and turnips or potatoes, or any two good crops can be raised in one year, in place of a fallow, the produce will be double in quantity what it has been under the former system." It is added, that there are about nine millions of acres in England and Wales in the course of two crops and a fallow; that is, six in crop and three in fallow; from which it appears, that, by procuring one crop in place of the fallow, one-half more is added to the former produce.

But it is admitted by those who contend most strenuously for the practice of fallowing on soils which are unsuitable for the turnip husbandry, that by proper management of the course or rotation, the fallow may be protracted for several years; and we have the authority of Mr Dickson of Bangholm, in the vicinity of Edinburgh, for stating his opinion of the practicability of having recourse to that system only once in 12 years, when the following six course shift, 1. fallow, 2. wheat, 3. hay, 4. oats, 5. beans, 6. wheat, is adopted, and when the wheat is cultivated according to the drill husbandry. Here it may be observed, that the soil is a fine loamy clay, and that although turnips are not included in the rotation, they follow in the second course. If, then, it appears from this statement, that the period when fallow becomes necessary can be prolonged, might it not be suggested that the extended improvement of this system of rotation might keep the land in a clean and fertile condition, and thus supersede entirely summer fallow?

According to Sir John Sinclair, in his Hints on the Agricultural State of the Netherlands, fallows are more rarely practised in Flanders than formerly, and in some districts are totally abolished. The succesion of crops which is pursued on strong land, in the neighbourhood of Bruges, is the following: 1. fallow, 2. winter barley, 3. beans, 4. wheat, 5. oats; sometimes there is a fallow every fourth year, and sometimes wheat and fallow alternate. But in the plain of Fleurus, in the Walloon country, fallows are now rarely seen. At one period, fallows were enforced, by a clause in the leases, as part of the system of husbandry in that fertile district. M. Mondez, who was well acquainted with Flemish husbandry, when he entered on the possession of a farm near Fleurus, having stipulated that he should be at liberty to pursue a different plan of management, took the lead in this improvement; and, for a period of forty years, has seldom had occasion to undertake a summer fallow. The beneficial effects of his system induced his neighbours to imitate and adopt it. The course of cropping pursued by M. Mondez, and in which a fallow is not introduced, is the following: 1. winter barley or wheat, 2. rape, 3. half wheat half rye, 4. clover, 5. oats, 6. flax; or where flax is not cultivated, the course proposed is, 1. winter barley, 2. rape transplanted; 3. wheat, 4. clover. The culture of beans is succesfully practised, instead of a fallow, by M. Wieland near Ostend. The beans are succeeded by an abundant crop of wheat or winter barley; and it is added by the agriculturist now alluded to, that "this system merits to be encouraged, from the great advantage derived from it; for, without any additional manure, which, however, it tends to furnish, it retains the fields in as high a state of fertility as can be done by the fallow system; it exacts but a moderate degree of attention, and it requires neither any extraordinary expence, nor hazardous combinations."

Sir John Sinclair informs us in the work just mentioned, that it is now a maxim in the plain of Fleurus, where fallows are nearly abolished, that whenever it is possible to manure the land fully every ninth year, they are perfectly unnecessary; and the same author notices a paper on this subject by M. Burtin of Brussels, who recommends mixing sand with the soil, to alter and improve its texture, and burning clay in large masses for the same purpose, as a substitute for fallows.

In Switzerland, fallowing was so much practised at one period, that it alternated with every crop; but now it is said that fallows are totally abolished in that country, and the rotation which precludes the necessity of that practice is, 1. wheat, 2. carrots, 3. vetches, 4. barley, 5. potatoes.

It has been already noticed, that the fertility of the soil which is frequently turned up and exposed to the atmosphere during the course of a summer fallow, instead of being improved and enriched by receiving something from the air, is actually impoverished by the loss of those volatile ingredients which might have contributed to the nourishment of a crop. But it can scarcely be doubted, that the saline or soluble matters in the soil, which are necessary to the growth of vegetables, are either entirely washed off the land, or carried downwards into the sub-soil, in the progress of the fallowing operations. It is supposed, indeed, that some compensation for this loss is obtained from the additional manure furnished by the weeds which are ploughed down. It seems, indeed, not improbable, that the soil is in a worse state in point of fertility at the conclusion of a clean fallow than it was at the commencement; and it deserves serious consideration, whether in any or in all the cases in which this system is adopted, any mode of practice could be devised which could obviate this loss, and at the same time secure the advantages of a clean soil with an improved texture. It would be easy to institute a series of experiments for the purpose of ascertaining the change which takes place in the fertility of the soil after a clean summer fallow. If two portions of land in the same situation, of the same nature and quality, and of the same extent, were marked, and if the one were put under a hoed or drilled crop of any description, while the other is at the same time subjected to the usual processes of fallowing; and if in the succeeding years the same crops were raised on both,—the amount and quality of the produce would furnish a fair estimate of the difference of fertility, if any existed, in the two portions of land thus treated.

Operations of fallowing.—When a summer fallow is determined on, the first operation is a ploughing immediately after harvest, and it is recommended that this ploughing should be as deep as the soil admits. In many cases, it is found beneficial to bring up a portion of the sub-soil, by means of which deep rooted weeds are loosened, and some addition of fresh earth, provided it be not of an injurious quality, is made to the cultivated soil. The decay of the stubble and weeds which are turned down, is greatly promoted by this ploughing. But, if circumstances prevent this first part of the process from being completed about the end of autumn, it must not be omitted during a favourable time in the winter months, or early in the spring season. In the first ploughing, if it can be accomplished, the old ridges are gathered up, that the soil may be kept dry through the winter. But if the ridges in their former state were considerably raised, it is not unusual to split or divide them into two; and sometimes when the land is dry, it is ploughed according to the method denominated crown and furrow, or the furrows and crowns are exchanged, the former becoming the crown and the latter the furrow of the new ridges, and sometimes two ridges are ploughed together by casting.

When the field is ploughed, all the furrows, as well those which divide the ridges, as those between the extremities of the ridges and head ridges, are to be carefully opened up by the plough, after which every remaining obstruction is to be removed, that there may be no interruption to the escape of the water. Attention also is necessary to the hollow places in the field, that a free outlet for any water that is apt to collect may be made. No water should be allowed to stagnate in any part of the field.

When the spring seed-time is over, the fallowing operations are resumed by another ploughing; and if the ridges were formerly split, they are now ridged up, and if the ridges were formerly gathered, they are now split. The field is subjected to a cross-ploughing; and after remaining a sufficient length of time to become dry, and to be fit for harrowing, it is repeatedly harrowed and rolled, to reduce and break down the soil to a proper and uniform consistence, while all kinds of roots and weeds which are raised to the surface are carefully collected into heaps to be burnt in the field, or carried off to form compost manure. The fallow is then ridged up, which prevents any injury from rainy weather, and a new surface is presented to the action of the harrow and roller; and after harrowing, the weeds are again collected and treated in the same way. The operations of ploughing, harrowing, and rolling are repeated, till the soil is completely cleared of weeds, and reduced to that uniform state of minute division, or of texture and consistence which is well known by the name of fine tilth. It must be observed, too, that in each successive operation, the weeds which spring up from seed are turned down and destroyed; and hence summer fallowing affords the best opportunity of clearing land which is infested with such noxious productions.

Some diversity of opinion prevails with regard to the implements employed in the fallowing process. Repeated ploughings, some think, are only necessary for the destruction of root weeds, which being turned up and exposed to the action of the sun and air, are completely deprived of their vegetative powers, and thus are not only rendered harmless, but are made to contribute, in their decomposition and decay, some useful ingredients for enriching the soil. But it appears from ample experience, that couch-grass and other root weeds can rarely be extirpated from some soils by the operation of the plough, to the exclusion of the harrow and roller. In stiff adhesive clay grounds, the soil is raised in masses or clods, which in no period of a dry season are so reduced as to permit the included roots to be affected by the drought, and to wither and decay, or the inclosed seeds to vegetate and spring up, that they may be afterwards buried under the surface and destroyed. In such cases, the application of the harrow and roller is most essential;—by the action of the latter, the earthy clods or masses are broken down and reduced to a loose friable mould, and by means of the former, the same effects are still farther extended, while at the same time the detached roots and weeds are dragged to the surface, and may then be collected by manual labour, carried off the field, or thrown into heaps to be burnt, and the remains blended with the soil.

By such operations the land is effectually cleaned from all kinds of noxious vegetables, and brought to that uniform degree of friability, or state of fine tilth, which the healthy and vigorous growth of the cultivated crops requires. The object of the last ploughing is to form the ridges. This is accomplished exactly in the same way as has been already described for striking the furrows; and as all traces of the former ridges are entirely obliterated, the direction, breadth, and other circumstances of the new ridges, may be accommodated to the nature of the crops to be raised, or the particular system of husbandry to be adopted. In preparing for a drilled crop, for instance, the breadth of the ridges is made to correspond with the proportions of the drilling implements in use.

In Norfolk, a kind of fallow, provincially denominated a *bastard summer till*, is occasionally practised. If it shall appear that a piece of ground, from which clover, or some other cultivated grass has been cut, is not sufficiently clean for the reception of the succeeding wheat crop, it is ploughed two or three times, if it can be accomplished, before harvest; and when it is necessary, the assiduous application of the harrow and roller is not to be neglected. For the purpose of cleaning pea stubble, it is also sometimes subjected to a similar series of operations. When the crop of pease is removed from the land, the straw is harrowed up, collected, and carried off. A single ploughing is given; after which the ground remains in that state till the conclusion of the harvest, when it receives two cross ploughings, and a fourth as a preparation for the insertion of the seed.

Application of manure.—When manure is necessary for land which has been under summer fallow, the fertility of the soil, the state of its tillage, and the nature of the manure, serve to direct the mode of its application. In cases where lime, or other calcareous matter, is found requisite, the summer months are properly recommended as the best time for spreading it on the land; but particularly after the mechanical operations on the land are completed, that it may be ploughed in with a slight furrow, not buried deep, which should be carefully avoided, but thoroughly blended and incorporated with the soil, that its effects may not be placed beyond the reach of the vegetative processes on which they are expected to operate. When farm-yard manure is applied, it is most beneficially inserted with the seed furrow, by which the vigorous growth of the crop is promoted by a regular and copious supply of nourishment in the early stages of its progress. The rich verdure and luxuriant appearance of the first crop after fallow, managed in this manner, afford ample proof of the advantages of this practice. In some cases, the abundant supply of vegetable matter to the soil by the decay of an abundant growth of weeds, may render the application of manure less necessary; but it may be fairly doubted, whether the unavoidable waste of fertility in the course of a summer fallow may not require some compensation, so that a certain portion of some enriching matters may be generally considered indispensible. It has been supposed to be a more economical practice to reserve the manure, and apply it to the second crop in succession after the fallow; but this point, it is obvious, can only be correctly determined by the comparative fertility of the soil.

Sect. III. *Drill husbandry.*

For the successful practice of the drill husbandry, or the method of inserting the seed in rows, or drills, the various tillage operations require to be executed with greater care, accuracy, and neatness than are usually bestowed on land when the ordinary broad-cast manner of sowing is adopted. This method of cultivating grain in drills is also denominated the *New Husbandry*, to distinguish it from the broad-cast system, and on account of its later introduction into this country; although it is supposed that the practice of cultivating grain and other crops in drills has

Arable land.

been known and followed in eastern countries from the remotest periods.

The drill husbandry was introduced into Britain by Mr Jethro Tull, a Berkshire gentleman, who began to cultivate his own property according to this method about the year 1713, and hence it has been called *Tull's Husbandry*. Struck with the remarkable effects which this method of managing arable land produced, and ascribing to the more perfect culture which was practised, rather than to the fertilizing properties of the manure, the more abundant crops which he obtained, like other speculatists, his partiality to his own system became excessive, and led him to disregard the benefits derived from manure, and even to consider its application as a needless waste of labour and expense. By thus over-rating the advantages of drilling crops, and by this erroneous view of the effects of this method, the introduction of the practice was probably much retarded. In the present day, when the utility and necessity of manure are so well understood and fully appreciated, no great danger exists of any person of ordinary intelligence, without some peculiar predilection, being misled by such a doctrine, and far less to venture to direct any extensive practice by such tenets; although we have heard that Mr Tull has still one follower, who thinks that perfect tillage is all that is necessary for the production of abundant crops.

In the broad-cast system, although not a necessary consequence of the practice, the land is often not in a proper condition or state of fine tilth; the seed is often scattered at random; in some places it is too thick, in others too thin, which allows weeds to spring up, so that labour and manure are wasted in vain; the seed is often imperfectly covered; part of it is carried off by vermin; part is exposed on the surface to rain, frost, and drought; the unequal depth at which it is placed, produces an unequal crop; and the soil cannot be stirred, or the weeds destroyed, without great expense or injury. But the drill-husbandry is free from most or all of these inconveniencies and defects. The land must necessarily be better tilled; the seed is regularly inserted, and it is placed at equal depths, which secures a clean and equal crop; by being speedily and equally covered, it is protected from vermin and injuries of the weather; weeding by the hand or horse-hoe is executed more completely, without risk of hurting the growing crop; by the repeated stirring of the soil, the roots of the plants have the full advantage of its fertility; the pulverised soil absorbs more freely the moisture necessary for the growth of the plants; and the intervals between the rows admit a free circulation of air, which is also essential to healthy vegetation.

The advantages derived from the practice of drilling are stated to be, a saving of seed; its more regular and certain growth and maturity, from being more regularly deposited; a more abundant crop, and of better quality; the more certain and easy destruction of weeds; harvesting the crop at less expense, as it is free from grass and other weeds; and the soil being left in a more friable state, and in better condition, which renders it more productive for future crops. The objections to this system of husbandry refer to the requisite dexterity and accuracy in performing the necessary operations—qualifications which are not always possessed by common labourers; the superior culture which must be given to the land, and for which every soil is not suitable; the thinness of the crop, the supposed waste of land, and the unproductive crops which have succeeded those that were drilled. Some of the objections now enumerated, it is pretty obvious, have their origin in prejudice, and others are undoubtedly to be ascribed to partial and inaccurate observation.

The comparative experiments of Mr Amos, which are fully detailed in his Treatise on Drill Husbandry, exhibit, in a distinct point of view, the superior advantages of this method. These experiments, which commenced in 1783, were made on soils of different qualities; and in all of them, two acres of land, laid up in ridges of 11 feet, and drilled and sown broad-cast, alternately, were employed. For the entire details, we refer to the work itself; we propose, for the sake of brevity, to state only the results; and the sum, opposite to the name of the crop, denotes the superiority of the drilled crop.

	L.	s.	d.
Oats on stiff loam, - -	1	3	0
Cole-seed after the oats, - -	0	1	0
Barley after the cole-seed, -	1	5	3

Wheat after the red clover, -	1	16	0
Cabbages, on stiff loam, horse and hand-hoed, in favour of the former	2	10	9

But we have to adduce a recent and still more decisive experiment in favour of drilled crops, which was made on a considerable scale, in the year 1815, by one of the most accurate and intelligent agriculturists, in a district where husbandry has attained a high degree of perfection. Mr Dickson of Bangholm, now alluded to, whose opinion of fallowing we have already stated, has distinctly and satisfactorily ascertained, that his crop of drilled wheat, on a black, sandy loam, yielded one-fourth more produce than an equal quantity of land of the same quality in the same field sown broad-cast. The quality of the drilled wheat also maintained its superiority over the other; for it was from four to six pounds heavier in the bushel than the produce of the broad-cast sowing, and the quantity of light grains in the former was less than one-half of what appeared in the latter. It ought to be added, that though Mr Dickson employed the same quantity of seed in both methods of sowing, the drilled seed was inserted in a furrow of six inches, and that he considers the saving of seed, which has been held out as one of the advantages of the drill-husbandry, as rather injurious, and as the cause of a deficient crop.

A remarkable difference is observed in the produce of drilled crops in the same kind of soils, from a difference in the distance between the rows or drills. This is strongly exemplified in the crops of potatoes and cabbages, noticed above, in which the more abundant crop was obtained from the wider drills, if part of the superiority be not ascribed to the difference of culture between the use of the horse and hand-hoe. A comparative view of the produce of different crops of grain and pulse, drilled at different distances, is given by Mr Young, in his Eastern Tour. But it seems doubtful whether any useful results are to be obtained from this comparison; because it is made on very different soils, in different situations, and under the management of different persons. It would seem, in general, that the most abundant crops were raised in the wider drills, at least within certain limits; and it must be observed that these limits are narrow; for when the difference is considerable, the result was greatly varied. The wheat crops were drilled from eight to 18 inches; the barley and oats from nine to 12 inches; the beans from nine to 20 inches; and the pease from 10 inches to two feet.

It is a curious fact in the history of agriculture, that Tull proposed and practised the drilling of wheat, barley, and other corn crops, in distinct rows, at the distance of three or five feet from each other. In this practice, as might be expected, he has found few followers. But although this extravagance in his system be laid aside, its importance and value have not been overlooked. Drilling is practised in rows of eight or ten inches distant, for the purpose of hand-hoeing; in rows at the same distance with the view of saving seed; and green crops are drilled and horse-hoed, to preclude the necessity or frequent recurrence of summer fallow. By sowing in drills at eight or ten inches, to admit the operation of hand-hoeing, taking the previous culture and the clean condition of the land, which is the consequence of attentive management, into the account, very abundant corn crops have been produced by Mr Ducat, at Esher, in Surrey, who has practised this method on a larger scale than any other agriculturist in the kingdom. But the requisite number of hands, it seems probable, is not always and in all situations to be procured for such extended operations. It is doubtful, from the fact noticed above, where the same quantity of seed was used in drilling as in broadcast sowing, whether, in all cases, the saving of seed ought to be considered as one of the advantages of the system. The compensation for the extraordinary previous tillage to bring the land into good condition for the drilling process, and for the additional labour which is necessary to keep it in a clean state in the progress of the crop, is to be sought for rather in the more abundant produce than in the saving of seed. The drilling and horse-hoeing of green crops is justly regarded as one of the most beneficial improvements in modern agriculture. It is considered very properly as an extension of the garden culture to the field, which some writers seem disposed to think is a thing altogether impracticable, and affect to treat even the most distant hint of the possibility of so refined an improvement with an indignant sneer, as if the progress of art had reached its utmost boundary, and the wants of man did not still exist to rouse ingenuity and stimulate labour to useful exertion.

In the preparation of land for the drill husbandry it is not necessary to repeat the directions already laid down for conducting the operations of perfect tillage, either in the case of ordinary practice, or in that of summer fallowing. It is sufficient to remark, that the ground on which a drilled crop is proposed, should be in the best condition with regard to the texture of the soil, and its state of cleanness. The quality of the soil, and the kind of drilling apparatus to be employed, regulate the proper breadth of the ridges. On a moist soil narrow ridges are necessary, but ridges of a greater breadth are preferred on a dry soil. The general breadth, when not otherwise limited to the drilling machine, is from five or six to fifteen or eighteen feet.

The distance between the rows in drilled crops varies according to the nature of the soil, and the kind of plants which are cultivated. On light soils, the drills should be closer than on those of a stronger and richer description. The distance between the rows for most kinds of corn crops, is recommended to be from ten to fourteen inches, and on poor soils eight inches; for beans, pease, and turnips, when drilled in double rows, at the distance of nine inches between the rows, and 27 inches in the larger intervals; but some writers are of opinion, that 10 or 12 inches are a sufficient distance for turnips, rape, and similar crops in poorer soils; and for carrots 14 inches is considered a proper distance.

Sect. IV. *Of the Culture of different Crops.*

The observations which have been offered on the subject under consideration, respect the nature of the soil, the means of improving and the methods of preparing it for the reception of the seed, and the growth of plants. Our attention is now to be directed to the particular management of the different kinds of crops which are usually raised upon it; and as the same succession of crops is never produced in all soils and situations, it seems of little importance in what order they are treated. The proper rotation of crops, which is regulated partly by the quality of the soil, and partly by local circumstances, will be discussed in the next section.

Of the plants which are produced on arable land, some are cultivated for the sake of their seeds, as the grain crops; some for the sake of their leaves, as the grasses, clover, cabbages; and some for the sake of their roots, as potatoes, turnips, carrots.

1. *Wheat.*

The soils which are the most suitable for the culture of wheat are those of a strong, loamy, or rich clayey description; but where an abundant supply of manure can be obtained, and when the climate is favourable, wheat may be profitably cultivated on soils of a lighter nature, as on any kind of clayey or loamy soil. On a strong soil, in good condition, and in a clean state, wheat may be raised every second year, alternating with some green crop.

Preparation of the land.—Wheat is often the first crop after summer fallow. In the application of manure to this crop, and those which are cultivated in the rotation, it is sometimes inserted at the conclusion of the fallowing operations, and sometimes, as has been already noticed, it is deferred to the next crop, and then it is applied to the wheat stubble for drilled beans. This is regarded by some as the best preliminary preparation for the next wheat crop. The limitation or extension of the course depends on the state in which the land is kept with regard to cleanness from weeds during the drilled bean crop, and on the manure which it receives, to keep up the proper degree of fertility. By this management, a rotation of fallow every fourth year, two crops of wheat, and an intermediate crop of beans, with a single application of manure, may be advantageously established. But if the fallow be introduced every sixth year, three crops of wheat and two crops of beans, with two applications of manure in the course, may be taken; and with three applications of manure and a fallow every eight year, seven crops may be raised in succession, namely, four of wheat and three of beans. On the different courses now noticed, it may be observed that the proportion of manure is smallest in the first, and soil of a good quality is found to continue in a proper degree of fertility. But in the other two, the rotation cannot be long persevered in without the extraneous acquisition of manure, and this can only be secured in the vicinity of large towns, or the disproportionate application of what is produced on the land.

Although wheat be generally sown after the land has received the preparation of a complete summer fallow, it may be raised to more advantage, according to some agriculturists, after different kinds of green, root, and other crops. The practice of sowing wheat after fallow is strongly reprobated by Mr Young, in his Calendar of Husbandry, who remarks, that " if there be one practice in husbandry proved by modern improvements to be worse than another, it is that of sowing wheat on fallows." " If fallows, (he says) be thought necessary, let them be sown with barley or oats, or any thing but wheat. But wheat may be advantageously cultivated after clover, tares, pease, beans, turnips, potatoes, and similar crops, regulating the succession according to the nature of the soil and the condition of the land." Beans which have been under suitable culture, are considered by Mr Young the best preparation for a crop of wheat; and in the opinion of the same author, clover and tares come next in order as preparatory crops.

The place which the wheat crop holds in a six course shift, on a fine loamy clay soil, in the highly cultivated district of East Lothian, in Scotland, is the following: 1. fallow; 2. wheat; 3. grass; 4. oats; 5. beans; 6. wheat; and, with an intermediate application of manure, all the crops are abundant; and besides, if the wheat be drilled, which affords an opportunity of clearing the ground from weeds, the fallow may intervene only once in 12 years. With the advantage of manure from Edinburgh, which compensates what is lost by the produce sold off the possession, Mr Dickson's rotation at Bangholm is, either, 1. potatoes; 2. wheat, drilled; 3. clover, cut green;—or, 1. turnips; 2. wheat or barley; 3. clover, cut green. The soil on which this succession of cropping is pursued, is partly a black sandy loam on a retentive sandy sub-soil, and partly a light sandy loam on a dry sandy under-soil.

Whether wheat be sown on fallow, or whatever be the preceding crop, it is scarcely necessary to observe, that the soil should be in a friable and pulverised state, and completely cleared of weeds. When wheat succeeds beans, the state of the weather in a variable climate may seldom permit more than one ploughing. But before this is attempted, the preliminary operation of cross harrowing the land is recommended, for the purpose of levelling the ridgelets, and of allowing the work of the plough to be executed with greater accuracy and neatness. To preserve the crop from the effects of moisture during the winter, the ridges should be gathered up, and, it is needless to add, that the furrows in all cases should, with the same view, be kept free and open. A greater degree of attention is necessary to the ploughing operations when wheat is sown after clover, that the grass roots may be completely buried and covered up; for when this labour is carelessly executed, the roots are apt to vegetate and send up shoots, to the great injury of the wheat in the early stages of its growth. To obviate this inconvenience, it is the practice in some districts to use the skim-coultered plough, or the common plough, to the coulter of which an iron fin or plate is attached, by means of a screw, at the distance of about four inches from the point, for the purpose of cutting or skimming off the remains of clover and grass plants from the surface, and turning them into the bottom of the furrow. By means of this implement the land is better cleaned, and the harrowing is more perfectly executed. In some cases, where the land has been two years under clover, it is broken up about the latter end of June, and receives two, and sometimes three ploughings. In favourable situations and seasons, when the soil can be brought into good condition, this practice, which is pursued in Norfolk and Warwickshire, holds out the advantage of a cutting of grass in the early part of the season when the land is broken up.

Kinds of wheat.—The varieties of wheat which has been cultivated for such a length of time, and in such diversity of soil and situation, may well be expected to be very numerous; and these varieties, it is remarked by attentive observers, are annually increasing. All the kinds of wheat which are usually cultivated in this country, are included under the smooth or polled wheat, and the wheat with a rough or bearded ear. The first, or the smooth wheat, as it affords the finest kind of flour, is more generally cultivated where the soil is suitable; and the second species, sometimes known by the name of *rivet* wheat, yields a larger crop on the more stiff and wet clayey soils, and is less subject to diseases, so that it is preferred for such lands. The common wheat is best adapted to dry soils; and the bearded or *rivet* wheat is thought by some to be most suitable for lands that have been newly broken up, where the excessive luxuriance of the crop may occasion the grain to be lodged in wet seasons; for in this kind of wheat the straw is firmer and stronger. The white and red varieties of the smooth wheat are in most general estimation; the first yields the whitest flour, and the last the most abundant produce. The varieties of wheat now mentioned are referred to the species *triticum hybernum* of Linnæus. The wheat which is usually sown after turnips belongs to the same species, and is called *spring wheat*, because it is sown in the spring season. It is worthy of notice, that the produce of spring-sown wheat should always be employed for seed at the same season; for it has been found from repeated experience, that the crop ripens a fortnight earlier than when the seed is taken from winter sown wheat. This is a point of importance at all times; but where there is danger of a late harvest, it is of no small moment. The true spring, or summer wheat, *triticum æstivum* of Linnæus, is a distinct species. In England it is sometimes known by the name of *May wheat*. It is supposed to be a native of Tartary, and was introduced into this country about the year 1773, under the name of Siberian wheat, and Switzerland wheat. This species has been extensively cultivated in Berwickshire and East Lothian, but has turned out to be inferior to the varieties of the Lammas or winter species, which have now replaced it.

It would be extremely difficult to describe all the varieties of wheat under cultivation in different districts, and, indeed, it could answer no good purpose; for it is probable that the same variety is distinguished by different provincial names in different places. The white varieties of wheat have been divided into the *thick-chaffed* and *thin-chaffed*, a distinction which is sufficiently correct, from the diversity of character of the two kinds. The thin-chaffed wheats are more hardy, and less liable to be affected with mildew, two very valuable properties, on account of which the culture of this variety has greatly increased in some of the most improved districts of Scotland. A variety selected by Mr Hunter of Tynefield, in East Lothian, is now in great estimation, on account of its superior produce and hardy character. It retains a green, healthy, and vigorous appearance in the coldest weather, when other wheats become languid and yellowish, and yields an abundant produce of excellent flour. In some parts of Berwickshire and Northumberland, a variety called *creeping* wheat, which belongs to the red wheats, is found to be very suitable for coarse clayey and moorish soils. The name is derived from its supposed tendency to push out suckers. It is a hardy and prolific variety on inferior soils. Beside the species mentioned above, there are others which are cultivated in different countries. One-grained wheat, *triticum monococcum*, is raised in Germany, and answers well in poor soils and exposed situations. In a trial with this grain in Scotland, it was sown on the 12th May, rose on the 27th, flowered on the 15th August and was fully ripe on the first of October. Spelt, *triticum spelta*, is also cultivated on the most barren soils in Germany. It was tried in Scotland, in a field 600 feet above the level of the sea, and ripened in the beginning of September. Smyrna wheat was brought from that place to France where it is extensively sown, at least in the northern districts on account of its superior produce.

Preparation of Seed.—It seems to be fully ascertained, that the produce of wheat sown without any preparation is more liable to be affected with the diseases to which that grain is subject, than the seed which has undergone some kind of preparation; and hence the practice of submitting seed-wheat to certain processes before it be deposited in the earth, is very rarely omitted. The experiments of M. Prevost, quoted by Sir John Sinclair in his Hints on the Agriculture of the Netherlands, shew the advantage of previous preparation in preventing smut in a striking light; the results were the following: 1. Infected grain without any preparation had one-third of the crop smutted; 2. Infected wheat, simply scalded, gave one-fifth smutted; 3. Sound wheat, without any preservative, had one-fifth part infected; 4. Infected wheat, well moistened in a solution of blue vitriol, or sulphate of copper, in the proportion of nearly two ounces for every three bushels of wheat, had only one hundredth part affected with smut; 5. Infected grain, well moistened with a solution of the same kind, in the proportion of about 4½ ounces of blue vitriol to three bushels of wheat, gave only one three hundredth part smutted. This solution is stated as being equally effectual in preventing mildew.

The method of preparing seed-wheat by this process, is the following. Three ounces and two drams of blue vitriol are dissolved in nearly four gallons of cold water, and this is the proportion allowed for every three bushels of wheat to be prepared. Into another vessel, capable of containing sixty or seventy gallons, throw from three to four Winchester bushels of wheat, and pour upon it the prepared liquid, till it rises five or six inches above the corn; stir it well, and remove the light grain from the surface. The wheat, after being half an hour in the solution, is thrown into a basket to allow the liquid to drain off. The seed is then washed with pure water, and well dried before sowing. It is said that it may be kept after this process quite sound for several months. A similar application of blue copperas is practised by Mr Butler of Derbyshire. He dissolves two pounds of the blue vitriol in as much urine as can moisten twelve bushels of wheat, and after it has soaked a sufficient time it is dried with quicklime.

The successful operation of the above mode of preparing seed wheat, has induced us to describe it at length. But whether it be more effectual than the ordinary methods practised in this country, which are preferable in point of economy, we have had no opportunity of obtaining precise information. Brine, or the solution of common salt in water, is strongly recommended by some as an excellent preservative for securing wheat from smut. The solution is made pretty strong, and the seed-wheat is thoroughly steeped in it. Sea-water, when it can be obtained, is sometimes employed, on account of being a cheaper application, as a substitute, with the same view. But it may be necessary to add a portion of salt to bring it to the proper degree of strength.

The most economical steep for seed-wheat is certainly stale urine, and it is at the same time, in the opinion of most agriculturists, one of the most efficient applications for preventing smut. The method of using it is thus described in the General Report of the Agriculture of Scotland: "Take four tubs, two smaller and two larger, the former of a size to hold about a bushel of wheat, and the latter large enough to hold the smaller within them. The smaller tubs have wire bottoms. Fill one of the large tubs with water, and, putting the wheat in the small one, immerse it in the water, and stir and skim off the floating grains; renew the water, and continue the operation till it come off nearly clear; then take out the vessel containing the wheat, and immerse it in the other large tub which is filled with urine. When thoroughly washed and skimmed let it drain; then throw it on a clean floor and riddle quick lime upon it, turning it over and mixing it with a shovel till it is sufficiently dry for sowing. Sprinkling the seed with urine is also found to answer the same purpose; and it should be observed, that seed prepared with urine must be sown immediately after the operation, for if kept long it runs the risk of being deprived of its vegetating power.

Kiln-drying is stated as an effectual preventative of smut; but great care is necessary in conducting the operation, to avoid such a degree of heat as might destroy the powers of vegetation. Passing seed wheat through rollers, which separates a black powdery matter from the surface of the grain, has been for many years successfully practised by Mr Henderson, near Wooller in Northumberland, for securing the crop from smut; and the same method has been adopted by Mr Dickson at Bangholm. An objection was made to this operation, that the vegetative functions of the grain might be destroyed; but the appearance of Mr Dickson's crop affords ample proof that the objection is groundless.

Time of sowing.—The nature of the soil, the state of the weather, and the preceding crop, must often occasion variations in the time of sowing wheat. When wheat succeeds a fallow, it may be sown from the end of August to the middle of November; or where the climate is favourable, as late as December. Some think that the best season, whether on fallow, or once ploughed clover stubble, is from the beginning of September to the middle of October. In East Lothian, on good dry gravelly loam, it has succeeded well after a clover crop when sown in November. On wet clay soils, an early sowing is recommended, to preclude the danger of losing the opportunity of completing the harrowing operations till the spring. For cold backward soils, September is considered the best season; and for soils of a warmer and drier description, October is preferred by some for sowing wheat.

When the sowing of wheat is deferred till the spring, the seed may be inserted at any favourable time from the beginning of February to the middle of March. When later, in Scotland, than the second week of March, the success of the crop is considered doubtful. But in the southern districts of the kingdom, the sowing season may be protracted to the end of April or beginning of May.

Methods of sowing.—Wheat is sown either broadcast or in drills. The first method is most generally employed, especially on the stronger kind of soils, whether they be of a clayey or loamy nature. The seed is cast over the surface in the usual manner, after the last ploughing, and immediately covered in by the operation of the lighter kind of harrows. In some districts the seed is sown in a partial manner, one portion being covered by the second or third ploughing, and the other afterwards harrowed in. But no great benefit seems to be derived from this method; and indeed if the business be not carefully executed, and particularly if the seed be not turned in with a shallow furrow, part of the seed may be lost, and an unequal crop may be the certain consequence. In broadcast sowing the seed must be deposited at a very unequal depth.

Drilling, or sowing wheat in rows, is more generally practised in the southern than in the northern districts of the kingdom. The distance of the rows is from nine to fourteen inches, varying according to the condition and fertility of the soil. The seed is usually deposited by machines, which sow several rows at once. The breadth of the ridge is often accommodated to the machine; and in this case half the ridge is completed by one journey, or the whole breadth is sown by once going and once returning along the ridges. Drilling is attended with the advantage of regulating the depth of the seed, which is extremely uncertain and unequal in the broadcast method. This depth is varied in different soils from two to four inches. Mr Dickson of Bangholm, near Edinburgh, whose practice in drilling has been remarkably successful, sows wheat in a furrow of six inches deep. The distance between the rows is from ten to twelve inches in the lighter kinds of sandy loam soils, fourteen inches on a stronger description of soil, of the nature of black sandy loam. The advantages of Mr Dickson's method of drilling over the broadcast sowing in the same soil, and in the same field, fully warrant its recommendation where the soil and situation are similar. The produce from a comparative estimate was at least one-fourth greater, the grain was of a better quality, weighing from four to six pounds heavier, and there was not half the quantity of light wheat.

Quantity of seed.—The quantity of seed varies according to the fertility of the soil, the state of the climate, and the period of sowing. On a rich soil, in good condition, and sown early, the quantity need not exceed two bushels for each acre. From two to three bushels, and in some cases a little more, may be considered as the extreme proportions. When sown on bean stubble, the quantity ought to be greater than on fallow; the proportion on clover ley should be larger; and the allowance of seed to turnip land sown in spring is recommended to be still more liberal. The English acre is here alluded to.

After-management.—It is scarcely necessary to urge the advantage of keeping the land sown with wheat free from water at all times, by opening up all the furrows, to allow it to have a free outlet. Weeding, as far as it is practicable, should never be omitted. This is very limited in fields sown broadcast. Thistles, and larger plants, which can be removed by the hand, can only be destroyed. But in the drilled method the business of hand-hoeing can be effectually executed; and it is not less beneficial to the crop in stirring the soil and closing it on the roots than in eradicating the weeds.

When grass-seeds are sown in the spring they are covered in by harrowing, an operation which is also useful to the wheat crop, and is often had recourse to in the latter view alone, for loosening and pulverising the soil, which is apt to cake and become hard in the course of the winter. Rolling wheat-lands in the spring, especially such as are of a porous description of soil, is a very beneficial practice, in giving it the proper degree of texture and consistence, as well as in breaking down and reducing any hard masses or clods of earth. Hand-hoeing is employed sometimes before the sowing of grass-seeds, to prepare the surface for their reception, and sometimes after they have been deposited, for the purpose of covering them in, according to the condition of the soil and the state of the weather.

By loosening the earth, and closing it round the stems of the plants, *tillering*, or the production of new stalks, is greatly promoted, and particularly in the drill-husbandry. Some curious facts of the wonderful multiplication of grain by this process are recorded. In a moderately good crop of drilled wheat, Sir Humphry Davy has counted from 40 to 120 stalks from a single grain; and he quotes Sir Kenelm Digby, who saw, in 1660, in the possession of the Fathers of the Christian Doctrine at Paris, a plant of barley which they preserved, and which consisted of 249 stalks from one seed, and yielded 18,000 grains. He refers also to Mr Miller of Cambridge, who sowed some wheat on the 2d of June 1766, and on the 8th of August a plant was taken up, separated into 18 parts, and replanted. In September and October they were again taken up and divided into 67 separate parts, to remain during the winter; and in March and April they were also taken up, when they produced 500 plants. The number of ears from a single grain amounted to 25,509; and the grains were estimated at the amazing number of 576,840. The produce, weighing 47 lb. $7\frac{1}{2}$ ounces, measured three pecks and three quarters of corn.

When blanks or thin spaces appear in the wheat grounds, from the effect of frost or the ravages of the wire-worm, which are not unusual, especially in broadcast sown fields, it has been the practice in some of the northern districts of the kingdom to sow barley in the vacant spots. A better method of accomplishing the same purpose, is to sow summer wheat, *triticum æstivum*, which, although inserted as late as the first week of May, arrives at full maturity as soon as the crop of winter wheat.

The feeding down of wheat crops is a practice which has been resorted to in some districts, when they appeared too forward or luxuriant in the early spring months. Some benefit was supposed to be derived from the removal of the upright central stems by which the growth of the lateral shoots become more vigorous; but if this practice be at all useful, it should undoubtedly be limited to crops of excessive luxuriance, or in strong and fertile lands. Some advantage is also supposed to be derived from the treading of the animals on the lighter and looser kinds of soil, by which the earth is pressed more closely to the roots of the plants; but in many cases it is suspected this practice is injurious, by retarding the period of blossoming, and checking the growth of the stems.

The wheat crop is often attacked by worms, slugs, and insects. To destroy these animals, and prevent their ravages on the grain, top-dressings of various substances have been employed, such as sea-salt, lime, sand from the sea-shore which is often covered by the tides, and soot; but it should be observed, that such substances as are of a corrosive nature should be applied in small quantity, and very equally distributed, that the young plants may not be injured. Rolling the land in the spring months, early in the morning, is recommended for destroying snails, slugs, and grubs.

Diseases of wheat.—Wheat, although to be considered a hardy plant, is more liable to diseases than other crops of grain. In the disease called *smut*, the substance of the grain is converted into a black powder, which is similar in its chemical properties to the dust of the puff-ball or dusty mushroom, *lycoperdon globosum* of Linnæus. Sir Joseph Banks, who has investigated the nature and progress of this disease with a good deal of attention, concludes, that the grain is destroyed by a small parasitical plant of the fungus tribe; but in what way the plant is propagated, it is impossible to say:—Can it be by the minute seeds being taken in by the roots, carried along with the juices through the vessels, and deposited in the ear where it vegetates, according to certain speculations; or by the seeds being wafted through the air, according to a prevalent popular notion, that the disease is conveyed from the barberry tree, in which a species of fungus sometimes makes its appearance? But whatever be the origin of smut, and other diseases to which wheat is subject, it seems to be a well established fact, that they are induced about the time of sudden changes of weather, when it seems probable that the functions of vegetation are enfeebled or interrupted; and it is also another well known fact, that plants, as well as animals, in a weak and languishing state, are most liable to become the habitation of parasitical beings, both of a vegetable and animal nature. The disease of smut is less frequent in a favourable season, when the growth is uniform and vigorous; and the steeping process, by which the disease is diminished or prevented, might be supposed to give a stimulus to the plant which remains, and enables it to resist alternations of heat and moisture through its whole existence. But although this may be the progress of the disease, it leads to no explanation of its origin.

Two species or varieties of smut are mentioned by some writers. In the one, the dust is contained in a pellicle or covering, forming balls which occupy the places of the grains in the ear. In the other, the form of the grain has entirely disappeared, and nothing remains but a few fibres of the husk or chaff, loaded with the black powder in a loose state, and without any covering. But it is more likely that it is the same disease, or the same fungus, in a more advanced period of its growth, when the ripened vesicles have burst, for the purpose of disseminating the plant.

Mildew is also a disease of wheat, which is supposed likewise to arise from a fungus of the same or of a similar nature. In mildew, sometimes the stem, and sometimes both the stem and the ear, are attacked, and the grain becomes small and shrivelled.

Blight is supposed to be an internal affection of the ear or spike of the wheat, which produces a total or partial deficiency of seeds, or, when the disease is less violent, renders the grains small and light. This disease is induced when heavy rains fall at the time when the wheat is in flower; but mildew succeeds heavy fogs or mists, or cold rainy weather, in the summer months, between the period of flowering and ripening. *Rust* is another disorder of wheat, in which an orange-coloured dust appears on the stem and leaves, and the plants become weak and languid. It is also ascribed to a vegetable parasite, and comes on in the time of excessive heat and unusual drought. *Red gum* is another disease, in which the chaff of the ear becomes of a deep orange colour.

Ripening of wheat.—In deciding on the proper time for cutting down wheat, the distinction between the ripeness of the grain and that of the straw must be attended to; for in some seasons the straw becomes yellow from the root upwards, indicating the appearance of ripeness, while the grain in the ear is soft and immature. It is considered of some advantage to cut down wheat before it is completely ripe, because it is apt to fall out of the ear during the harvest operations. But it should not be reaped in too green a state; for the grain shrivelling in drying injures its appearance, and the quantity of produce is diminished. The most proper time for reaping wheat and every kind of grain is, when that part of the stem which joins the ear affords no juice by expression. In that state, the grain which is clear skinned and fine, and the straw, are more valuable. When the harvest promises to be early, the crop may remain on the ground till it is more fully ripened; but in a late harvest, when winds and moist weather are apt to prevail, it may be cut down in a state of less maturity. Wheat fully ripe before cropping, is attended with inconvenience and loss during that operation; the ears break off from the stems; the grain drops from the husk, assumes a dark hue, which injures its appearance and quality in the market, and the flour from such wheat is of an inferior kind.

Harvesting.—In a dry season, and when the crop is free from succulent weeds, the wheat may be carried to the stack-yard in a few days after it is cut down; and when the straw is quite ripe at the time of reaping, it may be put upon the stack almost immediately from the sickle. By examining the joints of the straw of wheat or of other grains, a pretty correct judgment may be formed of the proper time of carrying them in. When they appear succulent and full of sap, some delay must take place; but if they are perfectly dry, no danger may be dreaded of stacking the grain; but if the crop be thrashed early, for seed or any other purpose, it must remain longer in the field, till it is thoroughly dry.

Another test, by which some husbandmen judge of the proper state of the grain for being carried to the barn-yard, is, by thrusting the hand into the centre of the sheaf; and if the sensation of cold be excited, the corn is considered as not sufficiently dry.

Stacking.—Omitting the description of putting up the grain in the form of stacks, and of covering and securing them from the weather, we shall only notice, that much advantage, both in saving the grain and preserving its quality, is derived from building the stacks on circular frames of timber, which are supported by feet of wood, stone, or cast-metal, and so constructed as to prevent the access of mice or rats, which often commit great depredations. They are also useful in obviating the injurious effects of damp grain, as a freer circulation of the air is admitted from below and through the whole rick, when a central funnel, or air-hole, is carried up while it is building. Round stacks, which are almost universal in Scotland, are considered preferable to those of an oblong form: although in the construction of the latter less time and labour are required, yet they are liable to the serious objection of interrupting the circulation of air in the barn-yard; of being more liable to injury in damp weather; and as they present a greater resistance to the wind, unless they are well secured, they are apt to be overturned.

Thrashing wheat.—The advantages of thrashing out grain, and particularly wheat, by means of machinery, have been already detailed in the description of the thrashing-mill. Even the produce of smutted wheat is cleaner, and in better condition, by the operation of the machine than by the *flail*; for it is less blackened during the operation, and, by careful dressing, the smut-balls may be completely separated, and the wheat sent to market in a clean state. When it is thrashed by the flail, it remains long on the damp barn-floor, during which the black powder attaches itself to the damp grains, and can only be removed by washing; but by means of the thrashing-machine all the operations are performed without interruption, and succeed each other so rapidly that the dry grains have no time to attract damp, and the whole of the black powder is easily separated, leaving the produce perfectly clean.

Produce.—The produce of a wheat crop must vary according to the nature of the season, and the fertility and condition of the soil. In Scotland, 40 bushels from the English acre are considered a large produce on fertile soils in good condition; but sometimes, in a favourable season, 47, and even 55 bushels have been obtained; from 24 to 30 bushels are regarded as a fair average crop on soils of a middle quality, under good cultivation; but when the produce is diminished to 18 bushels, the crop is considered scanty. In England, the produce, in some seasons, is under 20 bushels; while, on the same soil, and with the same culture, it exceeds 30 bushels in other seasons. The greatest produce of an acre in Middlesex, which has been recorded, amounted to 68 bushels; the smallest produce was diminished to 12. The average produce of Britain is supposed not to exceed 20 bushels from each acre.

2. *Rye.*

Rye may be raised on most kinds of land, but light and dry sandy soils, which are unsuitable for wheat or barley, seem to be most adapted to a crop of rye.

As poultry are less apt to attack rye than most other kinds of grain, it is thought most proper to be cultivated on those parts of the possession which are in the vicinity of the farm buildings; and in former times, when rye was an object of more frequent culture, it was not unusual to sow a ridge for the purpose of protecting the other crops from the depredations of domestic fowls. Rye may be raised after early field-turnips, clover, pease, and similar crops, and in some cases after clean fallows. As rye approaches nearly to the nature of wheat, it requires the land to be clean, and tolerably pulverized. When it is to stand for a crop, it is usual, in some places, to prepare the ground with some kind of fallow; but when fed off by sheep, a single ploughing only is given, for when the crop is sufficiently eaten down by the animals it is fallowed for turnips.

Time of sowing, &c.—There are two varieties of this grain, the winter and spring rye, or the black and white, or Dantzic rye. The winter rye is large, plump, and hardy, and is generally preferred. It is so hardy as to resist the effects of the severest weather. When intended for green food, it should be sown in August or September; but it succeeds by sowing it in October, and during any of the winter months, till the beginning of March. The quantity of seed, when a crop of grain is intended, from two to two and a half bushels is sufficient; but for green food three bushels, or even a larger proportion, may be employed. As rye germinates slowly, it is recommended to put it into the ground when it is in a dry condition, otherwise much of the seed is lost, particularly in a wet season.

After-management.—When the object of the crop is to afford a supply of green food for sheep in the early months of spring, no farther culture is required after it is put into the ground; but when a grain crop is expected, hand-hoeing and weeding ought to be carefully practised in the early stages of its growth.

The yellow colour of the stems, the drooping of the ears, and the hard, plump, and full condition of the grain, indicate the ripeness of the rye crop; and when the grain is free from weeds, and cut down in a dry season, it may be almost immediately carried to the stack-yard. Poor, sandy soils, on which rye is sometimes cultivated, yield but a scanty crop; on those of a better quality, the produce is from two to three quarters from the acre; but in the North-Riding of Yorkshire it amounts to three and sometimes to six quarters.

3. *Barley.*

Wet, heavy, and tenacious soils are unsuitable for the profitable culture of barley, which is to be considered as a tender and delicate plant. It succeeds best on sandy loams, or light and moderately dry soils; even light, poor soil, in a dry and warm situation, affords a crop of barley of superior quality to what is produced on strong lands of a cold and moist nature. Barley is usually cultivated after turnips, potatoes, beans, pease, or tares.

Preparation of the land.—Whatever be the crop which precedes barley, it is necessary that the soil should be reduced to a fine pulverized state, to insure an equal and perfect vegetation of the crop. This is effected by shallow ploughings and harrowings, and by occasional cross ploughing and rolling. In soils free from weeds, scuffling is recommended as a substitute for cross-ploughing; but in preparing the heavier kinds of land for barley, ploughing in autumn, and scarifying and scuffling, when the seed is put into the ground, are considered sufficient. When barley succeeds turnips, it has been long a practice in Suffolk to drill the seed without ploughing; but ploughing as early in the spring as possible, and giving a second ploughing immediately before the insertion of the seed, is pursued in Norfolk, where the barley crop on turnip fallow is generally well managed. When barley is sown after pulse crops, it is usual, in most districts, to give the first ploughing in autumn and the second in March.

Kinds of seed.—Different species of barley, and different varieties of these species, are cultivated in Britain. The two-rowed barley, *hordeum distichon* of Linnæus, includes several varieties, which have received different names in different places. These varieties are distinguished by the names of early and late, or *hot seed* and *cold seed*, from the circumstance of the former coming to maturity in a shorter period than the latter. Scotch barley, from being long cultivated in Scotland, belongs to the first, or quick growing variety. In the same variety is classed the *Rathripe*, or *Hotspur*, and *Sprat* barley, which is also known by the names of *Battledore*, *Fulham*, and *Putney* barley, because it is extensively cultivated in the vicinity of those places. The second species of barley in this country is the four-rowed, *hordeum vulgare*, or *tetrastichon*, which is well known by the name of *bear*, or *big*, or *rough bear*, in Scotland. This species, of which there are several varieties, answers well for elevated situations, late climates, and inferior soils. Six rowed barley, *hordeum hexastichon*, is a species which has a strong reed or straw, grows rapidly, and ripens early; is very hardy, and withstands the severity of winter, from which it is called *winter barley*. It is this species which is chiefly cultivated in Russia, and as far north as any grain is raised. It has seldom been an object of culture in Britain, although the trials which have been made were so satisfactory as to encourage their farther extension. In some cases, barley comes up irregularly, and ripens unequally. To obviate this inconvenience, steeping the grain is recommended, for the purpose of promoting the vegetation, and rendering the crop more uniform. The addition of a portion of soot to the water in which it is steeped is suggested for the destruction of insects. The best seed is of a pale bright appearance, without stain at the end, and full, plump, and well bodied.

Sowing barley, &c.—Barley, like wheat, is sown either broadcast or drilled, and it is recommended that the seed should be inserted immediately after ploughing, or on the *hot fur*, as it is called in Scotland, that is, while the turned up soil retains its moisture. In the southern districts of the kingdom, barley sowing begins about the latter end of February or the beginning of March; and in the northern parts the commencement is a month or six weeks later, and it continues to the middle of May, and even sometimes longer, according to the species or variety which is cultivated; but when the land is in good condition, early sowing of every kind of grain in the spring is always desireable, to insure the maturity of the crop. The quantity of seed varies from two to four bushels for the acre. A rich soil requires a smaller proportion of seed than such as is poor and exhausted; and a smaller quantity is allowed for an early than for a late sowing, because the plants have more time to tiller or push out side-shoots; but it seems to be generally recommended, that the allowance in all cases should be liberal.

After-management.—As land under a barley crop is frequently sown with clover and rye-grass, rolling is a necessary operation, to close the earth about the seeds of the latter, and it is no doubt useful, especially in porous soils, to the former. The barley crop often suffers much injury from the attacks of the worm. The sudden change from a rich green to a yellowish hue, indicates the commencement of the ravages of this insect. The use of a heavy roller, either to render the loose parts of the soil more compact, and prevent the access of the worm to the roots of the tender roots, or to destroy it by the pressure is beneficial. To produce this effect completely, the roller should be so loaded as to require the power of three or four horses. Top-dressing, before the application of the roller, is suggested as a useful practice to diminish the injury; and if it can be counteracted till genial showers of rain fall, no farther danger need be apprehended. When the barley is drilled, hand-hoeing is necessary, either before or after the insertion of the clover and grass-seeds. Hand-weeding has been seldom resorted to; but in some of the best cultivated districts in Scotland it has been successfully practised, and especially in fields which are infested with wild mustard and radish. When these plants have pushed out two rough leaves, the weeding should commence.

Harvesting barley.—The management of the barley crop in harvest requires more attention than any other kind of grain, even when the season is favourable; but in bad weather it is attended with great difficulty, and often with serious loss. When barley is fully ripe, the straw becomes very brittle, so that the heads are exceedingly apt to break off in handling. It is therefore recommended to cut down the barley crop while the grain retains some degree of softness and the straw contains a portion of its sap. This circumstance renders the succeeding operations of drying in the field, and of stacking, a business of some nicety. On this account it must remain long in the field, to dry and harden, so that it is exposed to all the changes of the weather; and, on the other hand, if carried too soon to the barn-yard, the risk of heating in the stack is considerable.

Barley is cut down in the usual manner with the sickle, and sometimes with the naked scythe, or with the aid of a bow, to assist in laying the grain one way. When it has remained in the swath till it is dry, it is bound into sheaves, and stooked. This should not be delayed after it is dry, when the straw becomes brittle. Barley is stacked in the same way as other grain; but it seems to be more necessary to observe every precaution in avoiding the risk of heating, and for this purpose it is not unusual to leave a hole or funnel in the centre of the barley rick, from top to bottom, to allow a free circulation of air. With this view, open frames, or central bosses, are employed; but when such artificial apparatus is wanting, a bundle of straw is placed in the middle of the stack at its commencement, and as the building proceeds the straw is drawn upwards, and leaves an opening behind; and if communications with this central opening have been formed from different sides of the stack, a free current of air is admitted, which prevents both mustiness and heating.

Barley is thrashed in the same manner as other grain. Some difficulty attends the separation of the awns from the grain, which is effected sometimes by an additional apparatus to the thrashing-mill—sometimes by frequently passing it through the thrashing-mill itself—by the use of the flail—or by stamping with an implement, the extremity of which is covered with plate-iron, made like a honey-comb—or by a machine which has been lately invented, and which seems to answer the purpose most effectually.

Produce.—The produce of this grain varies according to the condition of the soil, the climate, and the kind of culture employed. The average produce of the whole kingdom is stated at from 27 to 30 bushels the acre. The average produce in Middlesex, and the turnip-lands in Yorkshire, is about 32 bushels; but in many other districts it does not exceed 28 bushels. The extremes of the produce of the barley crop are from 12 bushels, which must be considered a very poor one, to 50, and sometimes even 60; but in good soils, and favourable seasons, from 30 to 42 bushels may be estimated fair average crops.

4. *Oats.*

This kind of grain is of a hardy character, and may be raised upon almost every kind of soil; but the most abundant crops may be expected from strong, rich soils, which have been lately broken up from the state of grass; and on land of a cold, tenacious, and fenny description, the oat is preferable to any other kind of grain. Oats succeed well after all kinds of green and root crops.

Preparation of the land.—When oats succeed tares, early pease, and some other crops which are removed from the ground early in the summer, on soils which are too wet for being ploughed in the winter, a clean bastard fallow, and laying the land up into ridges, are recommended as the best preparation for early sowing in the spring. When grass lands are broken up for oats, a ploughing is given, commonly in January, that a stiff soil may be rendered friable by the frost. When wheat or barley is the preceding crop, it is usual to plough in the spring, and particularly in those cases where grass-seeds are sown. It is generally found that grass-lands afford the most abundant crop of oats. As they are a hardy grain, and affording a tolerable crop on every kind of soil which is not excessively exhausted, this has probably given origin to the careless manner in which the land is often prepared for the reception of this corn, and which has been

Arable land.

justly reprobated by intelligent agriculturists. It has been observed, that "in all cases it is a good practice to have the land in a fine state for the growth of this crop, which is best effected in the same way as for barley. It is perfectly absurd to suppose that it will not be equally profitable to the farmer to have the land in as good a state of preparation for this sort of crop as that of barley." In some districts ribb-furrowing, or slob-furrowing, which is performed by turning over the furrows at the distance from 12 to 18 inches on the unbroken land, by which the surface is exposed, the soil improved, and the root-weeds destroyed, is practised in the autumn; the harrow is applied in the spring, and a complete ploughing is given before the insertion of the seed. By this management, even stiff and heavy land is brought to an excellent condition for this kind of crop. It cannot, indeed, be doubted, that a fuller and more complete preparation of the soil than is usually given to the land for a crop of oats, would not only increase the quantity, but greatly improve the quality.

Kinds of seed.—The numerous varieties of oats, which have arisen from diversity of soil, climate, and culture, are referred to the same species, *avena sativa* of Linnæus. These varieties, which have received their names from the places where they have been selected or cultivated, are estimated according to the produce of grain or straw, the proportion of meal which they afford, and the peculiar property which they possess of arriving at maturity within a shorter or longer period. The *white* oat includes under it varieties, some of which ripen early and others late. Of the early kinds, the *Blainslie* oat has been long in reputation in Scotland, and answers for elevated and late situations. The *Angus* oat ripens late, yields an abundant produce, affords a sweet meal, and is well adapted to soils of an inferior quality. The *common* oat has been long cultivated, yields a large produce of grain and straw on good soils, and grows well on those of a poorer description, and as it ripens early answers well for a late situation. The *Poland* oat is a plump variety, ripens early, produces a large crop on a rich soil, and brings a high price in the market; but the quantity of straw is small, and it sustains great injury from shaking winds. *Church's* oat, a plump, heavy, and productive variety, which was long in great estimation on the richer lands on the banks of the Tweed, belongs to the Poland oat. The *Frieseland* or *Dutch* oat has a thin-skinned grain, and yields a large proportion of straw; is suitable for the better kinds of land, and is not ill adapted to weaker soils in sheltered situations. The grains of the *Siberian* or *Tartarian* oat are thin and small, and the largest are awned; the straw is tall and reedy, which renders it less fit for the purpose of fodder: but as it is of a hardy character, it may be raised on inferior soils. The *red* oat, so called from the reddish colour of the husks, was either selected or first cultivated on the estate of Magbie-hill, in Peebles-shire in Scotland, from which it has been denominated *Magbie-hill oat.* The grains are small, but the husks are thin, and the produce of meal is abundant. It ripens early, resists the force of the wind better than other varieties, and succeeds well in high and cold situations. But the potatoe-oat, which was discovered in Cumberland in 1788, and was afterwards introduced into Scotland, is now the prevailing variety on well cultivated soils in the northern and some other districts of the kingdom. On all deep and tender loamy soils, which have been broken up from grass, the potatoe-oat yields the largest produce both of grain and meal; but in soils of a shallow description the quantity of straw is less than from some other varieties. The record of the average prices of oats in Marklane, on the 16th October 1811, exhibits the most decided proof of the superiority of the potatoe-oat; for while the common kind of oat brought 32s. and the Poland oat 40s. the average price of the potatoe-oats was at 42s. the quarter. Potatoe-oats tiller more freely, and succeed better on soils where the Poland variety would scarcely defray the expense of harvest labour. Indeed, such is the superiority of the potatoe-oat, both with regard to its abundant produce in grain and meal, at least when it is raised in less elevated situations, that it is now generally preferred to every other variety. But it ought to be mentioned, that some degree of degeneracy is observed in this valuable variety of oats, in certain districts. The grains have become long and thin, the skin has increased in thickness, and sometimes the appearance of the protrusion of an awn is traced,—circumstances which indicate the necessity of attention to select the strongest growing ears, and the best formed grain for seed. It is worthy of notice, that the person who first introduced potatoe-oats derived considerable emolument from the growth and sale of that variety; but he was extremely careful in separating the small grain, and selling only the full, large, and perfect grains, for the purpose of seed, which always brought a high price.

Sowing, &c.—In the southern parts of the kingdom, oats are generally sown in the month of March, often in the end of February, and in some instances have succeeded well early in January. In the northern districts, the time of sowing oats is from the middle of March to the end of April; but, in general, early sowing, for the purpose of establishing the crop before the approach of warm weather, especially on dry and parching soils, as well as to afford a better chance of the young plants escaping the ravages of the worm, and to insure an early crop, ought never to be omitted.

Oats are generally sown broadcast, and the quantity of the seed varies from four to five bushels the acre. When the sowing is early, the smaller proportion is considered sufficient, but when it is later the larger proportion is necessary. The Poland variety requires a larger quantity of seed than the potatoe-oats. Sometimes larger proportions of this grain are allowed for seed. Eight bushels to the acre have been sown in Lincolnshire, and have afforded a better and more equal crop than with a smaller quantity, besides the advantage of ripening four or five days sooner than with thinner sowing. Oats have been more rarely drilled than other kinds of grain; but where this method has been practised its benefits have been obvious, and in such cases five bushels of seed to the acre have been employed.

When clover and grass seeds are sown with oats, they are covered in by a slight harrowing; and in light and friable soils the application of the roller, as soon as possible, is useful; but in other kinds of soil, it is better to defer this operation till the crop be advanced a few inches in height. The only other culture necessary for a crop of oats is, to keep it free from weeds by means of hand-weeding.

Harvesting.—When the straw appears of a yellowish hue, the grain becomes hard, and the husks open, oats are ready to be cut down; but as the earlier varieties are apt to shed the seed during the harvest operations, they require to be reaped before they are fully ripe; yet the precaution not to cut too green must be observed, for the produce is greatly diminished in quantity and quality. But, upon the whole, oats are a grain of a hardy character, and suffer less injury during harvest than other crops. The operations of stacking, thrashing, and preparing oats for the market, are similar to those already described.

Produce.—The produce of oats is extremely various in different soils, seasons, and situations. The particular kind which is cultivated, as being more or less fitted for the soil and situation, occasions considerable diversity in the amount of the produce. The quantity from an acre varies from 20 bushels, or even less, to 70 or 80. The value of the bushel of oats is to be estimated according to the proportion of meal which it affords. An opinion is prevalent, that oats are generally a more productive crop in the northern than in the southern districts of the kingdom; and it is also asserted that the grain is of a superior quality. Some writers have entered into speculations concerning the causes of this difference, without being at the trouble of ascertaining how far the fact is to be considered as established.

5. *Beans.*

Beans may be successfully cultivated on the strongest kinds of moist soils. They thrive equally well on stiff, clay land, and that of a loamy nature; but they succeed best on soil of a good depth. Bean crops are raised after wheat, oats, and clover, and newly broken-up grass lands. This crop is peculiarly adapted to ley grounds, where injury to the corn crop, from the attacks of the grubs or other insects, is apprehended. This kind of crop is also beneficial in breaking down and reducing the soil, and in promoting the decay of the grassy material and destruction of weeds by its shade.

Preparation of the land.—In some districts, a single ploughing, at the time of inserting the seed in spring, is all the preparation which is made for the reception of the bean crop; but it is a preferable practice to lay up the lands in narrow ridgelets early in the autumn. Some writers recommend the previous application of manure, when beans succeed a grain crop, as wheat, by which the strong and vigorous growth of the lateral shoots is promoted. In such cases the land should be ploughed into that form which is most commodious for the method of sowing to be adopted, as, in drilling, to suit the breadth of the drilling machine, and, in dibbling, to facilitate the operation of the scuffler or scarifier. This mode of ridging is peculiarly beneficial in heavy soils; the manure is retained in the middle of the ridge, and secured from being washed off in heavy rains; and the soil is in a dry state and in good condition for the reception of the seed in the spring. It is scarcely necessary to mention, that water-furrowing, after the ploughing in autumn, should on no account be omitted.

Kinds of seed.—In the vicinity of large towns, some varieties of the garden-bean are cultivated in the field, for the purpose of supplying the market with the produce in the green state; such as the mazagan, an early kind, the mumford, the long pod, and the Windsor; but the horse-bean is most generally admitted into field culture. The tick-bean is supposed by some to afford the most abundant crop. The large ticks are chiefly raised in Kent; but in Essex the small ticks are preferred on strong soils, because they afford the largest produce, and bring the highest price in the market.

Sowing, &c.—The bean-crop may be inserted as early as the month of January in sheltered places, and in the succeeding month in more exposed situations in the southern districts; but in the northern parts of the kingdom the month of March may be found a more suitable season for this purpose. The quantity of seed is from three and a-half to four bushels to the English acre.

The broadcast method of sowing beans is now rarely practised. For as this is one of the best fallow crops to precede wheat, the drill husbandry is most advantageously pursued; and, to have the full benefit of horse-hoeing, the drills should not be nearer than 27 inches. It appears from experiments made to ascertain this point, that such a distance between the drills affords the largest produce. The drills are formed by the plough; the seed is deposited by the drill-barrow; the intervals between the furrows are split up to cover the seed; and 10 or 12 days afterwards the field is levelled by cross-harrowing. But if the season or the soil render this mode of drilling impracticable, a spring furrow only is given; the drill machine follows every third plough, and the operation of harrowing concludes the business. The depth to which beans should be planted, is recommended to be about five or six inches. In the southern districts, it is the practice to dibble beans in rows a foot distant, and each seed two inches apart in the row. This method is expensive; but it admits of the land being well cleaned. In Essex, beans are dibbled on two-bout ridges, three feet broad, and in double rows on the crowns nine inches apart, with an interval of 27 inches. The bush, or short-tined harrow, is drawn over the surface to cover the seed.

After-culture.—The operations of hand or horse-hoeing, as the distance between the rows admits, are essentially requisite, not only for the luxuriant growth of the bean crop, but also as preparatory for the succeeding crop of wheat. When the plants have been 10 or 12 days above ground, the surface between the rows is scraped, for the purpose of loosening the weeds; and after the lapse of a few days, according to the state of the weather, a small light plough may be employed to remove the earth from the sides of the rows; the weeds in the rows are to be drawn out by the hand, after which the plants are earthed up, by the double mould-board plough. The same operations are to be repeated every fortnight or three weeks, or as often as shall be found necessary, till the crop come into blossom, when the earth should be carefully drawn to the roots of the plants, to promote the setting and filling of the pods.

The black, or dolphin fly, is exceedingly destructive to the bean crop in dry summers. To prevent its ravages, the tops on which it first settles are cut off with the scythe or some sharp instrument. In June or July, when cold nights succeed hot and foggy weather in the day, beans are liable to injury from blight, which causes the blossoms to fall off; but sometimes a second bloom appears, and affords a tolerable crop.

Harvesting.—The blackening of the pods indicates the approach of the bean crop to maturity; after which the pods open at the extremities, and the seed is apt to drop out; but before this happen, the beans should be cut down, to prevent the risk of loss. At the same time, it ought to be recollected, that the crop is in no small degree diminished in value and quantity when it is cut before it has reached a proper state of ripeness.

Beans are either cut with the sickle or scythe, or drawn up by the roots; the sheaves are left untied for some days, to dry slowly; they are bound up with woollen yarn, old ropes, straw ropes, or ropes of the pease sown along with them, and three or four sheaves are set up together. In stacking beans, the precautions already mentioned should be observed, especially in forming an opening in the centre of the rick, for the admission of air.

Produce.—The produce of the bean crop is stated at 28 and 32 bushels from the acre, in Middlesex; in Kent, 48 bushels of the common tick bean are obtained from the acre of good land; in Yorkshire the produce is nearly the same; and through the kingdom it varies from 16 to 40 bushels. The straw is not only useful as litter for horses and other animals, when it is well broken by thrashing, but also affords a nutritious food both for horses and cattle through the winter. For this purpose, it is considered little inferior to hay, particularly when mixed with pease straw.

6. *Pease.*

Pease are sometimes sown along with beans, and sometimes with oats, for the purpose of supporting their weak trailing stems; but the unequal growth and ripening of the different plants probably diminish the value of both crops. Pease succeed on almost all soils; but the best crops are obtained from those of a light dry description, in tolerable condition, and having a proportion of calcareous matter in their composition, without which, experience has shewn, the crop runs to straw, and the pods are imperfectly filled and ripened.

Pease succeed wheat, oats, and other grain crops, as well as clover or sainfoin, and are an advantageous crop on old ley grounds which are newly broken up, where the ravages of the worm are destructive to other crops. The more tenacious soils require a ploughing in autumn, as a preparation for the scarifier and scuffler in the spring. The soilshould be in a reduced and pulverized state, and a compost of earth, dung, and lime, is recommended by some, while others consider the application of manure as not only unnecessary, but injurious, in producing a luxuriant growth of straw, which is unfavourable to the podding, and encouraging weeds, which, from the nature of the crop, are with difficulty eradicated.

Kinds of seed.—Numerous varieties of pease are in cultivation. They have been divided into the early and the late kinds; among the former are the early *Charleton*, the *golden hotspur*, and the *common white pea*, which are usually cultivated in the southern districts, and in the neighbourhood of large towns, to be sold in a green state. The late pease include the varieties of the grey kind, which are more generally employed for field culture.

Sowing, &c.—Those varieties which are intended for the market in the green state, are sown in succession, with intervals of ten days or a fortnight, from the middle of January to the end of March. Sometimes the seed is sown in autumn; but it is a doubtful practice, except on a rich soil, in a warm and sheltered situation. For this purpose, the hardy *hog pea* should be selected; but for general crops, the grey sorts are preferred, and are sown as early in March as the condition of the soil admits. For general sowing, on land in tolerable condition, from 3 to $3\frac{1}{2}$ bushels of seed is a sufficient quantity to the acre. When sown early, a larger proportion is required. Broadcast sowing is sometimes practised; but drilling, as it facilitates the operations of cleaning the land from weeds, should be preferred. For hand-hoeing, the distance between the rows is from 12 to 16 inches; but when horse-hoeing is to be practised, the distance should be from 24 to 30 inches; the depth at which the seed is deposited is from two to three inches. In Norfolk, pease are drilled at nine inches distance; and when they are dibbled, two rows are planted on a flag, so that the distance is not more than four inches. In some districts, the drills are transverse and at 15 inches distant, and the seed is covered in by the hoe or bush-harrowing. Steeping the seed before sowing is rarely practised; but it seems to be useful in promoting the vegetation, and rendering the growth more vigorous and uniform.

After-culture.—When the width of the intervals is such as to admit of horse-hoeing, the first operation is to remove the earth from the rows, and afterwards to lay it up by splitting the intervals; but when hand-hoeing only is admissible, two applications are requisite; the first, when the plants are two or three inches high, and the second before they come into blossom. In the last hand-hoeing, the ground is well cleared of weeds, and the rows being laid down the earth is carefully drawn to the roots.

Harvesting.—Pease are reaped or cut up by means of a hook with a sharp edge, and collected into small heaps, which are set up against each other for drying. The early crops are put into loose open heaps, and when they are perfectly dry, are formed into stacks, to be employed as the food of animals. When pease-straw is intended for horses, it is recommended to cut it into chaff, and mix it with their other food. The pease which are not consumed as human food, are employed in fattening hogs, and other domestic

Arable land.

animals, and sometimes they are used as a substitute for beans in feeding horses; but as they are apt to produce gripes in the green state, they should not be given till they are sufficiently dry.

Produce.—The produce of pease is estimated by some at 28 or 32 bushels from the acre, while others suppose that the average of any two crops does not exceed 12 bushels. This crop, therefore, considering its direct value, is less profitable than many others; so that its ultimate advantage must be sought for in the improvement of the soil.

7. *Tares.*

Tares succeed best on gravelly loams, which are not too moist; but they produce a tolerable crop on almost every variety of soil, from the thin gravelly to that of a deep, stiff, and clayey description. After winter crops, tares are sometimes sown with a single ploughing, but two ploughings, with an intermediate harrowing, is considered a better practice; and when the soil is not rich, the crop is greatly improved by manuring. Tares usually succeed a crop of wheat or barley.

Kind of seed.—Two varieties of the tare, belonging to the same species, *vicia sativa*, are cultivated, and distinguished by the names of *winter* and *spring tare*, of which the latter is less hardy in its habits; and although it is difficult to discriminate the seeds of these varieties, they should always be kept separate, for the seed of the spring tare is unsuitable for the winter crop, and the seeds of the winter tare should not be employed for the summer produce. The difference is easily known when the plant springs up. The seed-leaf of the winter tare is of a fresh green colour, but the spring tare comes up with a grassy spear of a brown dusky hue.

In broad-cast sowing, the quantity of seed employed to the acre is from $2\frac{1}{2}$ to 3 bushels. In drilling, at the distance of six inches, 2 bushels are considered sufficient; but when the crop is to be cut for soiling, a larger proportion is allowed.

Time of sowing, &c.—Winter tares are sown from August to October; earlier on poor soils and exposed situations than in richer soils and more sheltered lands. The plants should be established in the soil before the approach of the cold season. The spring variety is sown from the end of February to the beginning of April, when it is intended to ripen the seeds; but when the crop is to be employed as green food, from the beginning of April to the end of May is a proper time for the insertion of the seed. Sometimes spring tares are sown in June, with a quart of cole seed to each acre, for the purpose of supplying weaned lambs in autumn with an excellent food. This method is successfully practised on the Down lands in Sussex.

Tares are usually sown broad-cast; and it is necessary to distribute the seed as equally as possible over the surface, and to cover it well by harrowing, to prevent the depredations of birds, and insure a perfect and uniform vegetation. Drilling, as it is practised in some of the southern districts, is recommended on all rich clean soils for this kind of crop. The distance between the rows is from six to eight inches.

After-culture.—Less attention than to most other crops is required in the management of tares, because the plants soon cover the land; but hoeing and weeding, which should be performed early in the spring, are undoubtedly beneficial. A light roller passed over the crop in the early spring months, when the season is dry, smooths the surface, and renders it fitter for the operation of the scythe.

Harvesting.—Tares are managed in the same way as pease, when they run to seed, and are preserved for that purpose. When tares are made into hay, the time of cutting is when the blossoms have declined, and begin to fall flat. The hay from tares is of a nutritious quality; but as it requires much sun and air to dry it thoroughly, and as it is very apt to be injured by moisture, it is more troublesome in its preparation than most artificial grasses.

Produce.—The produce of green tares has amounted to 12 tons from the acre in Middlesex, and when converted into hay to about three tons. The produce in seed from the acre has sometimes exceeded 40 bushels.

The most beneficial application of the tare crop is soiling with horses or other live-stock on the farm; but for this purpose it ought not to be cut down at too early a period. Eating tares in the field, by turning live-stock into it, is considered an improper practice, as it is not only destructive to the crop, but injurious to the soil. The tare crop is considered of such importance in Sussex, that a much larger proportion of stock is supported. All kinds of animals thrive upon it. A single acre of tares has maintained four horses in better condition than five acres of grass; and without any other food, twelve horses and eight cows have been kept for three months upon 8 acres of tares. The milk of cows fed with this plant is so much improved that it yields a greater proportion of butter.

Some other species of *vicia* are recommended as worthy of the attention of the agriculturist; as, the *bush vetch*, *vicia sepium*, which shoots early in the spring, vegetates late in autumn, continues green all winter, is supposed to be a valuable pasture plant, and no fertile soils might be converted into hay; and the *tufted vetch*, *vicia cracca*, which rises to a considerable height, and affords abundant foliage, so that it might likewise be used as green fodder, or preserved for hay. Poor lean cattle have been greatly improved by feeding on this plant. The everlasting pea, *lathyrus latifolius*, is a plant of large growth and foliage, is also recommended for the purpose of green food, or for hay, and is of a nutritious and fattening quality. *Chicory*, or *wild succory*, *cichorium intybus*, is a succulent, herbaceous plant, which is also employed as green food for different kinds of live stock. *Buck wheat*, *polygonum fagopyrum*, is sometimes cultivated for the same purpose.

8. *Potatoes.*

It is a curious fact in the history of the vegetable kingdom, that the potatoe, *solanum tuberosum* of Linnæus, the native of a warm climate, should be naturalised and extensively cultivated in northern regions, on account of its valuable properties, as an essential article of human food. The precise period of

Arable land.

the introduction of this root into this country is not distinctly ascertained; but it was known in England previous to the year 1597, as appears from the description of Gerard, in his History of Plants, printed in that year. He speaks of two kinds, the common and the Virginia potatoe, which he cultivated in the garden. It is not less curious to observe, that the long period of a century and a half elapsed before the cultivation of the potatoe became pretty general. The diversity of soil, situation and culture, to which the potatoe has been subject for great part of an hundred years, has given rise to numerous varieties, which are chiefly characterised by the quality of the root, quantity of produce, and period of ripening.

All the varieties of the potatoe have been included under two divisions, distinguished by the colour of the flower and the root; as, the red-rooted, which produces a purple flower, and the white-rooted, which bears a white flower. In Lancashire, where the culture of the potatoe is well understood, and extensively practised, more than twenty varieties of the early, and fifteen of the late kind, have been enumerated. In reference to the potatoes cultivated in England, it may be observed, that the old *winter-red* is regarded as an excellent variety for the table in spring, and is said to be less liable than others to the curl. The black potatoe is also a late kind, and keeps well till August. The *white* and *apple* varieties are best adapted for use in the early part of the season. The *royal*, or *Cumberland* early, is of a good flavour, and grows to a large size, ripens early, and affords an abundant produce. The *ox-noble* and the *cluster* potatoe, are the varieties chiefly cultivated as food for live stock, because they are very productive and large in size. The varieties of the potatoe which are in common use for the table in Scotland, are the *round white*, the *white* or *yellow kidney*, the *red*, *purple*, *streaked*, or *black*, which last is best fitted for being used in spring and the beginning of summer: the *white bloom*, *yam*, or *Surinam* potatoe, from its large size, and great produce, is chiefly cultivated as food for cattle.

New varieties obtained.—New varieties of this invaluable root are obtained by raising it from seed, by which the quality and productive powers of the plant may be greatly improved. When the potatoe apples come to maturity, and begin to fall spontaneously, they are collected and preserved among sand till the spring, when they are bruised among the sand, or among fresh mould, and the seeds are separated, and mixed equally with the mould or sand. They are then sown on well prepared, fine garden earth; and as the rough leaf appears, and the plants have sufficient strength to be safely handled, they are transplanted into another bed of fresh mould, in rows, and are to be kept clean during the summer. In autumn, clusters of small potatoes, of different sizes, are found at the roots; these are planted in the succeeding spring, and produce larger potatoes, but they do not reach their full size till the third or fourth year. When a moderate artificial heat or shelter, as that of a stove or garden frame, can be procured, the seeds may be sown earlier, so that they shall be ready for planting out as soon as the weather permits; and in this way the process is greatly shortened, for the roots are larger the first year, and attain nearly their full size in the second season. The quality of the potatoe, and its productive property, as they are more or less combined in the same plant, determine the choice in selecting the varieties of seedling potatoes which are to be preferred.

Soil and preparation.—The soil best adapted for the culture of potatoes is of a rich loamy description; but they are successfully cultivated, and the largest produce has been obtained on stronger kinds of soil. Excellent potatoe crops have been raised on mossy soils.

In preparing the land for potatoes, it is usual, in most districts where this root is much cultivated, to give the land one or two ploughings in the end of autumn; and in the spring, at the time of planting, to reduce the cloddy surface, and to bring it into good condition for the reception of the sets by the operation of the harrow. Sometimes the land is ploughed up about Christmas, and again in the middle of April; and with intermediate harrowing and rolling, it is brought into a proper state to be ridged up and planted.

Manuring.—Manure is almost invariably applied in the culture of potatoes, and it would appear, from experiments with different kinds, that the most abundant produce follows the use of farm-yard dung; but besides street-manure, which is extensively employed in the culture of this crop in the neighbourhood of large towns, various other matters, as wheat-straw, furze, broom, and similar plants, succulent plants, as clover, tares, and vetches, and peaty or turfy substances, have been successfully employed in the same way. On the sea-coasts, in the northern parts of the island, sea-weed has been found useful for the same purpose.

It seems to be generally understood, that a liberal allowance of manure is necessary to insure a good crop of potatoes. According to Mr Billingsley, 20 cart-loads, each of the capacity of 30 bushels, should be applied to the acre; and Mr Young recommends from 25 to 35 cubical yards, and where it is long or littery, to the amount of 40 cubical yards to the same extent of ground.

When the potatoes are drilled, the manure is equally distributed in the bottom of the drills; but for raising the early kind of potatoes, the application of manure to the preceding crop is thought by some to be a better practice; for in this way the excessive luxuriance of the stems and leaves is checked, the size of the root becomes larger, and its quality is improved. Mr Dickson of Bangholm, near Edinburgh, ploughs in the manure for the succeeding potatoe crop, with a furrow of seven or eight inches, in November or December; the land is cross-ploughed, about the 1st of March, with a furrow of 12 or 14 inches deep, and afterwards prepared for drilling. This method of applying the manure admits of the crop being planted earlier on lands which are of a soft and wet nature, and would not admit loaded carts, without injury, till a late period of the season; but, for early potatoes, he finds it the best practice to insert the manure in the drills.

Time of planting.—Potatoes are planted as soon as possible after the danger of frost is over, which, in the southern parts of the kingdom, is from the mid-

Arable land.

dle of March to the end of April; but, in the northern districts, the commencement and termination of the planting season are at least a month later. Early planting, during dry weather, always insures an earlier and more abundant crop, as well as of better quality.

Seed.—The selection of the varieties of potatoes to be planted depends on the object of the cultivator, whether it be intended to have an early or late crop, or whether it be destined for human food or for the support of live-stock; but whatever variety is preferred, it has been recommended that the seed potatoes should be taken from the finest and most perfect of their kinds, in which the eyes or buds being stronger, produce stronger and more vigorous plants, and afford a larger produce. Very extensive experience has amply proved, that the cultivation of the same kind of potato, for a continued succession of crops, in the same soil and situation, injures the quality, as well as diminishes the quantity of the produce. In those districts where the culture of the potatoe is practised according to the most improved methods, attention to the frequent change of seed is never neglected. The farmers in the neighbourhood of Edinburgh, who raise great quantities of this root, find, from experience, that the amount of produce, and quality of the crop, are most improved the second year after a change of seed; and proceeding upon this fact, they introduce such a quantity of a proper kind of seed, and from a suitable distance, as, being planted the first year, shall yield sufficient seed for their whole crop in the succeeding season. By this management, the curl is entirely prevented, the quality is improved, and the crop is abundant.

From numerous experiments on the comparative advantages of planting entire potatoes of a larger or smaller size, cuttings of different sizes, with one or more eyes, or shoots only, it appears that middle-sized whole potatoes, or large cuttings of large potatoes, uniformly afforded more productive crops than smaller potatoes entire, or small cuttings, or the eyes or shoots alone. Considerable diversity in the amount of the produce was observed in varying the distance of the sets in the rows from six to twelve inches. With the view of saving seed in times of scarcity, the shoots only are employed; but this saving is counter-balanced by many disadvantages. The shoots cannot be planted so early; many of them being weak afford little or no produce, and the crop is generally later in reaching maturity. In the use of the eye, or root-bud of the potatoe, the success of the crop has been various. In some cases, the produce seems to have been equal to what was obtained from larger sets, but in others, feeble plants, and a diminished crop, have been the certain consequence of this kind of seed. The quantity of seed or sets employed varies according to the distance between the rows and the space between each set in the row. When the sets are planted at 10 inches distance in every direction, each acre requires from 25 to 30 bushels; and when every other furrow is planted at the distance of a foot between each set, from eight to 12 bushels are sufficient.

Methods of planting.—On moist soils, intended for a potatoe crop, and under a damp climate, it is recommended to raise the land into one-bout ridges, which preclude the danger of injury from stagnant water; but dry and sandy grounds should be kept flat. In Lancashire, where the potatoe culture is well practised, drills are formed at equal distances, and of such width and depth as to contain the manure. The distance of the drills is such, that the horse which leads out the manure may pass in one furrow, and each of the wheels of the cart in others, on the different sides. The manure is equally distributed in the three furrows, by means of a crooked fork with two or three prongs. The distance of the drills is usually from 28 inches to three feet; the richer and more fertile soils require the largest space. The sets are placed upon the dung, and the plough is run along both sides of each drill, to cover the seed.

In some districts, where the soil is dry, the manure is equally spread over the surface of the ground, which has been well prepared by twice ploughing and harrowing. The sets are planted in every third furrow, and the dung and mould are turned down upon them by the plough. In this way a level surface is preserved, and the dissipation of moisture is prevented; but it can only be pursued where manure is abundant.

The method recommended for planting potatoes upon sward land is, after preparation by the use of a plough which pares off the surface, and deposits it in the furrow, to place the sets on the inverted sods, at the proper distance, and to cover them with mould from below, by a common plough. This method, in which the decay and decomposition of the turfy matters answer the purpose of manure, may be useful where it is scarce, or in bringing waste lands to the state of tillage.

In what is called the *lazy-bed* method of planting potatoes, the spade is employed. The land is formed into beds of six or seven feet broad, and three or four feet are left on each side for trenches. The surface of the bed is slightly dug over, the manure is equally spread, the sets are planted at the proper distances, and they are covered to the depth of three or four inches, with the mould dug from the side trenches. On retentive soils of considerable depth, good crops have been obtained by this method of planting; but it is less adapted to the thinner and poorer kinds of soil.

Dibbling is another method which is sometimes practised in planting potatoes; but in a comparative estimate of this method with the system of drilling, the superiority of the latter, in affording an earlier crop, and more abundant produce from the same kind of soil, and treated in the same manner, is very remarkable. But in whatever way the sets are inserted in the ground, the precaution of not planting them at too great a depth, and of covering them with fine friable mould, should be strictly observed. The depth of four or five inches is considered sufficient in dry soils; but a less depth may be necessary where the ground is moist and of a strong quality.

After-management.—The luxuriance and abundance of the potatoe crop depend greatly on the attention and industry which are employed in the cleaning and hoeing operations. It is recommended by some to harrow the land when the shoots from the sets un-

Arable land.

der the surface have advanced about an inch, which is to be ascertained by examination. By the operation of harrowing, the surface of the soil is not only cleaned from weeds, but loosened, to allow the tender shoots to push freely through it. A small folding harrow is recommended for this purpose, by which the weeds are destroyed, and the mould is applied to the opposite sides of the contiguous rows. When the potatoes are entirely up, the earth and weeds may be removed from them, by forming a shallow furrow with a small plough. The same operation is repeated after the lapse of a few days, and when the weeds, which are in this way covered up in the intervals, have decayed, the earth is returned to the plants by means of a double mould-boarded plough, which passes twice in the same track, and turns a slight furrow to each side. When the plants have reached the height of about six inches, the earth is raised still higher with the same implement. When it appears necessary, hand-weeding and hand-hoeing, to complete what is deficient in the operation of the plough, must not be omitted during the growth of the potatoe crop.

Curl in potatoes.—The disease called *curl*, which was first observed in Lancashire about the year 1778, soon spread very rapidly, especially in those districts where the culture of this valuable root was most extensive, and excited by its ravages no inconsiderable alarm that the country might be deprived of a very essential article of food. This, as might be expected, has been a fertile subject of discussion and speculation among agricultural writers. It would afford no useful information to enter into a detail of the causes to which the curl has been ascribed, or of the numerous and contradictory opinions which have been held concerning its origin.

The result of some experiments instituted by Mr Thomas Dickson, of the Broughton nurseries, near Edinburgh, and communicated to the Caledonian Horticultural Society, seems to prove, in a very satisfactory manner, that this disease in potatoes is owing to the plants or sets being taken from potatoes which are too ripe. This was first suggested by Sir George Buchan Hepburn, Bart.

In the autumn of 1800, Mr Dickson selected 14 pounds of a long flat potatoe, which he procured from Fifeshire, and he took one or two sets from each end of each potatoe, that is, from the extreme or wet end, and from the umbilical or dry end, next the connecting radicle. The sets from the different ends of the potatoe, were planted on the 27th April 1801, with the same quantity of manure, and in the same circumstances. In the end of June, all the plants from the wet, or least ripened end of the potatoe, had come up, and looked healthy, excepting three, which were slightly affected with the disease. These were thrown out, and such only as were quite free from it were preserved. Few of the plants from the dry, or ripest end of the potatoe, had appeared, and such as had sprung up were all in a greater or less degree diseased. In many instances the sets had not vegetated, and when the new crop was dug up, they were nearly as fresh as when put into the ground. The produce of both sorts was taken up on the 3d of October, and pitted, for repeating the experiment, which was prosecuted in the same way for 1802 and 1803. The results were invariably the same. The plants from the unripened ends continued healthy, and produced abundant crops, while those from the dry ends continued to degenerate. It ought to be observed, that the produce of the curled potatoes was taken up before being too ripe, and replanted with the others. The disease was not removed, but it was not aggravated. Mr Dickson recommends some rules, the observance of which may entirely banish the disease of curl from the country.

Arable land.

1. To procure a sound healthy seed-stock, which cannot be relied on unless obtained from a part of the high country, where, from the climate and other circumstances, the tubers are never over-ripened.

2. To plant such potatoes as are intended to supply seed-stock for the ensuing season, at least a fortnight later than those planted for crop, and to take them up whenever the *haulm* or stems become of a yellow-green colour. At this period, the cuticle, or outer skin of the tubers, may be easily rubbed off between the finger and thumb.

3. To prevent those plants that are intended to produce seed-stock for the ensuing year, from producing flowers or seeds, by cutting them off in embryo, taking care, however, to take no more off than the extreme tops; as by taking more, the crop may be injured. The best mode of doing this is with a common reaping-hook, or light switching-bill. Two boys or girls may do an English acre in two or three days.

Pulling off the blossoms.—To increase the size of the potatoe, and the amount of its produce, it has been the practice with some to cut away those parts of the potatoe plants which contain the flowers before the blossoms appear. In some trials that have been made, the flowers were carefully picked as soon as they appeared; in others, after they had expanded, or when the fruit had begun to set; and in others, after the fruit or apple was formed and half-grown; and it was found, that the produce from those plants whose blossoms had been plucked off, was nearly double of that in which the apples were allowed to ripen. The crop was also less productive from those plants where the flowers were suffered to waste themselves only; and when the apples had acquired some size, it was still smaller; but, in both cases, it was more abundant than those parts of the drills which remained untouched. The growth of the stems of those plants where the blossoms were plucked off was also observed to be more vigorous than on those where they were allowed to remain. In some other experiments which were conducted to ascertain the same point, it is said that no perceptible difference could be observed in the produce. The following account of experiments on this method of managing the potatoe crop, is extracted from Mr Wilson's General View of the Agriculture of Renfrewshire—a county in which the culture of potatoes is extensively and successfully conducted. "There have been," he says, "many trials of the effect of pulling the flowers or blossoms from the potatoe, to prevent the seed from forming, and the result has been an increase of produce. One gentleman, (Mr.

Arable land.

Wilson at Deanside, near Renfrew,) prosecuted this experiment with great care and attention during the years 1803 and 1804, in fields of two acres, each year, cultivated according to the usual mode, in drills, and planted in manure. By taking alternate portions of equal area in the same field, pulling the blossoms from some of these divisions, and leaving others to ripen the seed, attending in the autumn when the potatoes were taken up, and measuring the produce with great care, he uniformly found, both years, the quantity increased 10 or 15 per cent. where the blossoms were taken off, there being very few small potatoes in these portions of the field. He also found the quality much improved, in consequence of the crop *ripening sooner than usual* where the blossoms had been pulled, and therefore not affected by the frosts, which often set in so early that the growth of the potatoe is completely checked before it arrive at maturity. Having thus ascertained that the quantity and quality of the potatoe crop are much improved by pulling the flowers, he has continued the same practice for the last five or six years, on fields of from four to nine acres; and he considers this experiment well worth prosecuting to any extent. The blossoms are pulled by children from ten to twelve years of age, their wages 6d. per day, and the expence is about 3s. per acre. About four acres of potatoes, from which he took the blossoms in 1808, produced nearly 400 bushels each acre." It is stated by the same author, that experiments made in a different part of the same county serve to confirm the observation, that potatoes ripen sooner when the flowers are taken off.

In a letter published by Mr Young, recommending the extended cultivation of potatoes, it is observed, that this "plant possesses two modes of securing its reproduction, the one by producing tuberous roots, and the other by the general mode of flowers and seed-vessels. It has been ascertained by the ingenious president of the Horticultural Society, Mr Knight, that the plant employs the same fluid in both these operations; and by preventing the consumption of it in either of them, it is made to act more strongly in the other. Upon this principle, if a potatoe plant is carefully deprived of its tubers as soon as they are formed, it will be made infinitely more productive of blossoms and seeds. On the other hand, if its blossoms are picked off, and it is prevented from forming any seed at all, the fluid which would have been employed in that operation, will be expended in forming an increased crop of tubers. It is true, that men who have to attend to the management of hundreds of acres will hardly condescend to think of potatoe blossoms; but there are thousands of cottagers whose scanty pittance may be increased by the simple expedient of employing their children in preventing their potatoe crop from ever forming a seed vessel.

"As it is more than probable that poor people may be led, by the pressure of the times, to have recourse to the new crop of potatoes in their little gardens before they are ripe, and thus occasion a distressing waste in this valuable article of subsistence, the following directions for raising them, may serve, in a considerable degree, to diminish the evil. Instead of taking the shaws entirely out of the ground, as is the common practice, we advise them to apply the spade to the right side of one of the furrows, from which they must carefully remove the earth, until they reach the largest of the potatoes, which they may take up, without materially disturbing the stem. They must then, without loss of time, restore the soil to its former place. After going over the whole of their early crop in this manner, confining themselves always to the right side of each furrow, they may return on their steps, and withdraw the large potatoes in the same way from the left side. By this means the shaws are preserved entire, and the smaller potatoes rather assisted than stopt in their growth, by loosening the earth during the proposed operation."

Digging up and preserving potatoes.—The leaves wither and fall off, and the stems decay, when the potatoe crop is ripe; and no time should be lost in digging it up after these appearances, that it may be secured from the frosts, which are not unfrequent about the period when the later planted potatoes reach maturity. Potatoes are dug up with three pronged forks, or, when the field is large, by means of the plough, which goes twice along each ridgelet, and the potatoes are collected by women and children. When the soil is adhesive, the harrow is sometimes employed to break down the furrow-slice, that the potatoes may be separated from the mould. A light plough, without any coulter, is considered the most convenient implement for this purpose, as the potatoes are less in danger of being injured. Harrowing the land once or twice afterwards is recommended, to bring such potatoes to the surface as may remain buried in the soil. It is scarcely necessary to add, that a dry season should always be preferred for digging up the potatoe crop; and when the whole is raised from the ground, it is a useful practice to spread it thinly upon a dry floor, for the purpose of allowing it to become perfectly dry, before it is stored up for preservation through the winter. It is also useful to separate the small and bruised potatoes from those of a middling and larger size.

The great object to be kept in view in the preservation of potatoes, during the winter and spring, is to secure them from the effects of frost, moisture, and such a degree of heat as causes germination. This is accomplished in various ways; either by burying them in pits under the surface of the ground, or by covering them up with earth and straw, on a dry part of the field, by depositing them in vaults and cellars, or by placing them in houses appropriated to that use. When the situation is perfectly dry, the temperature most suitable for the preservation of potatoes is between the extremes of 48° and 32° of Fahrenheit's thermometer; as, on the one hand, they are not injured by frost, and on the other they are not liable to germination. But as such situations are not every where at command, the progress of germination in the spring and beginning of summer may be retarded, by carefully picking off the shoots, and exposing the potatoes to the sun, or by slight kiln drying, to exhale the moisture; and thus they may be kept much longer in a sound state.

Produce.—The nature of the season, the fertility of the soil, and the more or less perfect culture which is employed, must no doubt occasion great diversity in the amount of the potatoe crop. The produce has been stated to vary from five to eight or ten tons, and the average over the whole kingdom is estimated at six tons from the acre. In Yorkshire, from 300 to 400 bushels of the variety of the potatoe which is used at table, and from 400 to 500 bushels of the kind which is destined for feeding live stock, are considered a good crop. In some extraordinary cases, more than 600 bushels have been raised from an acre in Kent, and in others, the enormous produce of from 700 to 1000 bushels, have been obtained from a rich soil in a favourable season.

9. *Turnips.*

The turnip husbandry, on such soils as are adapted to the culture of that root, has contributed greatly to the present improved state of agriculture in Britain. The cultivation of turnips is an excellent substitute for a naked fallow; for in this way the entire loss of a crop is obviated, and the produce affords a valuable food for the support and fattening of live stock, in a season of the year when other kinds of food are usually expended. The nature of this plant, and the culture which it requires, retain the land on which it is raised in a clean condition, and afford an excellent preparation for such crops as require a fine friable soil.

Soil and preparation.—Turnips may be cultivated on soils of a thin, gravelly, or chalky nature, and even on loamy clays, if they are not loaded with moisture; but they succeed best on those of a light loamy description, or on deep sandy loams. But although turnips may be raised on soil of very different qualities, the success of the crop depends not less on its proper management, than on its fertility; for when the ground is reduced to a friable state, a fine bed is prepared for the seed, by which vegetation is quicker and more vigorous, by the equal diffusion of moisture, and the growth of small seed-weeds is promoted, which admits of their being easily eradicated.

When turnips succeed a fallow, four or five ploughings, with the intermediate operation of the harrow and roller, are necessary. The first ploughing is given about the close of autumn; and the remaining operations, as the cross-ploughing and harrowing, commence about the month of March. When the land is foul with weeds, it should be harrowed at the end of a fortnight; but when it is clean, it is left in its rough state till about the middle of May, when it is ploughed to the full depth, and immediately harrowed, if the season be dry, and the soil tenacious. The practice recommended by some is, to give the first ploughing to the full depth, and the after ploughings and harrowings are continued to the middle of June; but in all these the nature of the soil, the season, and the state of other field operations, are to be consulted. After grain crops, less preparation is required. In some cases, after paring and burning the surface of coarse pastures, good crops of turnips have been raised, by spreading the ashes equally, and by a single shallow ploughing, that the manure from the ashes might not be buried too deep.

Application of manure.—Every kind of manure is employed in the cultivation of turnips; and in general it is recommended to be deposited in the soil as nearly as possible to the period of inserting the seed. In the broad-cast method of sowing, the manure is spread equally, and either turned in with the seed-furrow, or by the preceding ploughing. The state of the soil, and the richness of the manure, must regulate the quantity which is employed. When the crop is drilled, a smaller quantity is sufficient; but as its success greatly depends on the vigorous vegetation of the young plants, the allowance should always be liberal; but lands in a fertile condition, which have been well manured for a preceding crop, may be prepared for the turnip crop without any new application of manure.

Kinds of turnips.—The varieties of the turnip, *brassica rapa* of Linnæus, which are chiefly cultivated in the field, are those of the round and long-rooted kinds. The root of the first kind is round and flattish; and as it varies in colour, has received the different names of *round, red,* or *purple topped, green topped, white topped, yellow, black,* or *red rooted, stone,* and *Dutch* turnip. The second kind is of a longish form, and distinguished by the names of *tankard, tap-rooted,* and *pudding* turnip. These varieties of the turnip are preferred in different districts, according to their different characters of resisting the effects of frost, the size to which they grow, and their qualities as the food of live-stock.

Sowing, &c.—The quantity of seed employed varies from one to two lbs. to the English acre. In the broadcast method in Norfolk, $1\frac{1}{2}$ lib. is sown; but on the sandy soils of Suffolk, and the lighter lands of Yorkshire, one pound is thought sufficient. Chalky soils require a larger proportion; but in general it is recommended as a good practice not to be too sparing of turnip seed, for the redundant plants can be easily thinned out by the first hoeing. The quick and vigorous vegetation of the turnip seed contributes greatly to the success of the crop. For this purpose, steeping the seed in water, or some other liquid, for a few hours, is recommended, before it be sown, and particularly in a dry season.

The time of sowing turnips is chiefly regulated by the mode in which the produce is to be disposed of. For early consumption, the seed may be sown about the beginning of June; but towards the end of the month, or about the beginning of July, is considered the proper time for sowing, when the crop is to be consumed in the early spring months. Mr Dickson of Bangholm sows turnips after hay, from the end of June to the 20th of July, and has been very successful in this practice of double cropping, which he thinks may be advantageously pursued on any turnip land which has not a greater elevation than 200 feet above the level of the sea. The turnips sown at this late period, by continuing their growth through the winter, are better enabled to resist the effects of frost.

Turnips are either sown broad-cast or drilled. The first method is more general in the southern districts, but in the northern parts of the kingdom drilling is more commonly practised. To admit of horse-hoeing, the distance between the drills is from 27 to 30 inches; and for the purpose of inserting the turnip seed with more regularity, the drill-barrow and other machines are employed, by which one or more rows are sown at the same time. The depth recommended, is from one to two or three inches, according to the moisture of the ground.

After-management.—Weeding and loosening the soil are peculiarly requisite in the culture of turnips. In the broad-cast method, hand-hoeing only can be practised. This operation commences about four or five weeks from the period of sowing, or when the plants have acquired four or five leaves. In the first hoeing, when the season is dry, the plants should not be thinned at a greater distance than six or eight inches from each other, that too much of the naked surface may not be exposed; and in the second hoeing, at the end of two or three weeks, they are thinned out from ten to twelve inches distance, while the soil in the vacant spaces is well loosened.

In drilled crops, the first operation after sowing, is to remove the soil from the side of the ridgelets on which the turnips are planted, for the purpose of destroying the annual weeds which have appeared. This work is performed by means of a light plough, or by implements peculiarly constructed for the operation. The plants are thinned in the rows by hand-hoeing, a labour which is usually executed by women and children. In ten days or a fortnight afterwards, according to the state of the weather and the progress of the crop, the earth is pared away from the sides of the drills, and turned into the intermediate space. The hand-hoeing is again resumed, and when the weeding operations are completed the intermediate ridgelet is split up, and laid back to the sides of the drills, by means of a small plough, or scraper; the double mould-boarded plough, or some other suitable implement.

Insects injurious to turnips.—The turnip crop is liable to be attacked by different insects. The turnip fly, *chrysomela saltatoria* of Linnæus, besides some other species, is its greatest enemy; for by wounding the seed leaves, or preying upon them, the young plants are soon destroyed. What is called the *canker* of Norfolk, is to be referred to the ravages of another insect, *tenthredo oleracea* of Linnæus, which is wafted over in myriads with the north-east wind from Germany, and in the course of a day or two destroys whole fields. The black caterpillar, which is supposed to belong to a species of *tenthredo*, commences its depredations on the turnip plants after they have made some progress. The ravages of the common gray slug, *limax agrestis*, are also extremely destructive to turnips; and when the growth of the plants is retarded, and they become feeble and diseased, they are preyed upon by the common earth worm.

No effectual remedy has yet been proposed for the destruction of these insects. The speedy germination of the seed, and the rapid growth of the young plants, when these can be promoted by enriching the soil, and seizing a favourable season for sowing, promise to be the most effectual means of resisting their ravages. With the same view, it has been recommended to steep the seed in water, train oil, lintseed oil, or some other oil, for 24 hours, and after draining and mixing it with finely sifted earth or sand, to insert it immediately in the soil. The use of seed of different ages, or steeping one half of the seed, that it may come up at different periods, is another method suggested, for securing the turnip crop; for as the appearance and departure of the turnip fly are extremely sudden, the plants which come up late often escape their ravages. Strewing vegetable ashes, quicklime, soot, or barley chaff, and sprinkling lime water, tobacco water, and some other liquids, have been practised for the destruction of the fly and slug; and rolling in the night, when the slug proceeds from its lurking place, with a heavy implement, or turning a flock of sheep upon the turnip lands, and keeping them constantly in motion by means of a dog and person to attend them, that the slugs may be shaken from the young plants, are also recommended for the destruction of that animal. Sowing radish seed along with that of the turnip, on the supposition that the radish plant is preferred by the insects, has been suggested as the means of preserving the turnip crop from the depredations of the fly; and planting cabbages in the same field with turnips, it is said secures the latter from the attacks of hares; but it is supposed that none of these practices is completely effectual.

Diseases of turnips.—Turnips are liable to a disease in the root, called *anbury*. A large excrescence forms below the bulb, and after a certain period becomes putrid, and emits a very offensive smell. This disease is ascribed to the puncture or wound of some grub or insect in the vessels of the tap-root. It is most frequent in dry seasons. The only remedy that offers itself, when the affection has taken place, is to remove the diseased plants, and to loosen the earth about those that remain; but by complete preparation, and enriching the soil on which turnips are raised, it is supposed the disease may be altogether prevented. The turnip root is subject to another disease, denominated, in some districts, *fingers and toes*, in which the turnip plant, instead of forming bulbs, sends off a number of separate roots. In some cases, the bulb itself is divided into lobes, but frequently the tap-root is the part which is chiefly diseased, when the bulb seems pretty perfect. These appearances are observed at a very early stage of the growth of the plant, and sometimes even before it pushes out the rough leaf. The leaves remain nearly unchanged, except in hot weather, when they become languid, and droop. In the investigations which have been made into the history of this disease, it has not been traced to the seed, the period of sowing, or any peculiarity in the soil; but it is supposed, from the facts which have been observed, that it may be ascribed to some undiscovered insect, which wounds the root in the earlier stages of its growth. It is said that this disease is most prevalent on fresh soil; and the only method which has yet been recommended for its prevention, is the application of marl, or fresh mould, mixed up with lime.

Produce of the turnip crop.—The season, the soil, and the mode of culture pursued, vary the produce of this crop; but 15 tons are considered as an average crop on an English acre of good soil. Sometimes it amounts to 25 or 30 tons; and in one case, in Ayrshire in Scotland, the enormous quantity of 60 tons was obtained from an English acre.

Raising seed.—To have seed of a good kind, it is best to procure it from turnips which are transplanted one year and sown the next; or if they are transplanted once in three years, it is supposed that the stock may be preserved in good condition. The turnips destined for the production of seed, are to be selected of the best kinds, and of the most perfect forms, from the field crops; and the tops being cut off, are to be transplanted in November or December into a well-prepared piece of ground, which is so situated that it may be protected from the depredations of birds. The seed ripens in July or August following. In some districts, it is the practice to cut part of the stems, to tie them up into sheaves, and when they are dry, to build them into a long stack for preservation till April or May, when the seed is thrashed out; but sometimes it is immediately thrashed out on a cloth, near the spot where it is produced, put into bags, and preserved in a dry situation.

Preservation of turnips.—The turnip crop which is destined for the support of live stock in the winter and spring months, is either consumed on the field, carried off, as it is wanted, to the feeding-houses, or removed entirely, in the beginning of winter, to some convenient place for preservation. The great mass of matter in the turnip root, and the large proportion of water which it contains, render it extremely liable to be destroyed by sudden changes of frost and snow. When the soil is of a moist and retentive quality, it is apt to be poached and injured by the treading of cattle in consuming the crop on the field, or by horses and carts in carrying it off; or when a wheat crop is to succeed the turnips, it becomes necessary in both cases to have them removed. Various methods have been proposed for the preservation of turnips. Sometimes they are piled up with dry straw in houses constructed for the purpose; and sometimes they are stacked in a convenient corner of the field where they grow, with intermediate layers of dry straw, which latter method is practised in Hertfordshire, and one load of straw is employed to 30 or 40 tons of turnips. The turnips are drawn by grasping the tops firmly in the hand; and after twisting the roots round, by which the lateral fibres are broken, and the earth loosened and separated, they are easily pulled up. A dry season should be chosen for this operation; the tops and tap-roots are to be removed, taking care to wound the bulb as little as possible; a layer of straw is spread on a dry part of the ground, and a layer of turnips, to the thickness of 18 inches or two feet, is placed upon it, after which layers of straw and turnips are arranged alternately, till the heap or stack be brought to a ridge or point. The edges of the different layers of straw are turned up, and serve to prevent the turnips from falling out, while they afford an external covering to the heap. The whole is then thatched over with long straw. In some cases, the preservation of turnips has been attempted without straw, by forming them into heaps called *pies*, in the way that potatoes are kept, and merely by thatching them over on the outside. It has been suggested also, that turnips might be built in small stacks, near the places where they are intended to be consumed, with the tops outwards, and with a little straw between the different layers. The stack is then covered over with wattles or hurdles, lined with straw. In some districts, after the turnips are drawn, and the tap-roots cut off, they are removed to a piece of pasture-ground near the farm-yard, and set close together upright on their bottoms. In this way the growth of the tops is little interrupted, and it is supposed by some that the quantity of nutritious food is increased. This operation should be performed in dry and windy weather, because the tops are then less brittle, and the roots are cleaner. The practice which has been suggested, of preserving turnips by means of ice or snow, might, no doubt, with proper precautions, be successful; but with a slight inattention, the whole heaps run the risk of being destroyed. The method advised is to cart the roots, in the time of hard frosts, into heaps, place them on bottoms of ice, and mix them with ice and snow, that they may be preserved in the frozen state till they are applied to use. When preserved in this way, the heaps may be constructed in suitable buildings, or they may be covered up with straw, heath, or some loose and dry material, and a covering of earth laid upon the whole. When the turnips which have thus been preserved are to be given to the stock, or when they are removed in the frozen state from the field for the same purpose, the precaution of putting them into cold water for a few hours, that they may be completely thawed, should not be omitted.

Yellow turnip.—This variety of the common turnip possesses many of the valuable properties of the Swedish turnip. It is hardy, resists the winter frosts without storing or artificial protection, is less liable to putrefaction, and even the wounded part is not apt to run into decay. It has a superior flavour, is more succulent and nutritious, and is preferred by cattle to the Swedish turnip. From these properties, it appears fitter for spring use than the common turnip; and the milk of cows fed with this yellow variety, affords butter which has all the richness of flavour and colour of midsummer butter.

The culture of the yellow turnip is the same as for the common turnip. Early sowing, and less space between the plants, as the roots are in general of a smaller size, are recommended by some; but in some cases, when sown at the same time with the common white turnip, it would appear that they equalled, or even exceeded them in size.

Ruta baga, or Swedish turnip.—The advantages of this excellent root, are briefly stated by Mr Young, who says, that " when the farmer has the right stock of seed, the root yellow in flesh and rough in coat, it lasts through all frosts, and may be depended on for sheep quite through the month of April, though drawn two months before, and spread on a grass field—that it is an excellent and nourishing food for sheep, and also for any sort of cattle—that it is equal to potatoes, keeping stock swine, a point of very great consequence—that it is, next to carrots, the very best food that can be given to horses—and that it is sown at a season which leaves ample time, in

Arable land.

case of a failure, to put in common turnips or cabbages."

Swedish turnip may be raised on soils which are too moist and heavy for the common turnip; but the land requires to be well prepared, and enriched with manure for this crop. Great care is necessary in raising the seed; for if the plants from which it is obtained grow in the vicinity of other species, they are liable to produce degenerated varieties; and this is supposed to be the cause of the occasional occurrence of a spurious crop of inferior quality. Swedish turnip should be sown three weeks or a month earlier than the common turnip. The quantity of seed is from two to three pounds for the English acre, in broadcast sowing, and in drilling a smaller proportion. New seed should always be preferred, and in a dry season steeping is found useful in promoting germination. The seed is sometimes sown upon beds of good soil, and when the plants are about the size of cabbage-plants, fit for transplanting, they are set in rows, at the distance of eight or nine inches in the row, with about a foot of interval; but sowing immediately on the field where the crop is to be produced, is recommended as the best practice. The after-management of the Swedish turnip is similar to that of the common turnip.

10. *Cabbages.*

The culture of cabbages is very limited in the northern parts of the kingdom, and is considered by some as forming no part of the profitable practice of husbandry; while others regard this vegetable as a valuable addition to the winter and spring food of live-stock, and warmly recommend it on such stiff and strong soils as are not adapted to the culture of turnips. The certainty of the cabbage crop, and the larger proportion of food obtained from the same space of ground, are also stated as advantages in favour of its cultivation. Different varieties of the cabbage plant have been employed in field culture; and as mixed or new varieties are extremely apt to be produced, when seed is raised from plants of different kinds growing near each other, great attention should be paid to have the plants which are selected for the produce of seed removed to a distance.

Turnip cabbage.—This variety of the cabbage derives its name from producing a bulb of a roundish flat form, which appears chiefly above the surface of the ground, and seems to be an enlargement of the stem of the plant. The leaves which surround it resemble those of brocoli. This plant is said to be more hardy against frosts than the Swedish turnips, is sometimes cultivated under the name of *Cape cabbage*, and seems to be the *Kohlrabi* of the Germans.

Turnip-rooted cabbage.—This variety of the cabbage has been sometimes confounded with the former; but it differs from it in forming the bulb below the surface of the ground; and besides, it is of an oblong shape, and the leaves approach nearly in appearance to those of the common turnip. But for a full account of the culture and application of cabbage crops, as well as that of rape or cole, which is also employed as green food in winter, for sheep and other animals, the reader is referred to Dickson's *Practical Agriculture.*

11. *Carrots.*

A deep soil, of a loamy or sandy quality, is the best adapted for the culture of carrots; but it is supposed that good crops might be obtained from soils of a more tenacious description, as clay loams, when perfectly dry and well prepared.

Deep ploughing is necessary for a crop of carrots; and where the land has been formerly in tillage, three ploughings may be found sufficient; the first to the depth of ten or fourteen inches, about the beginning of October; the second, a cross ploughing, to the same depth, in February; and the third, previous to the insertion of the seed, in March. The liberal application of manure is necessary for this crop, and it is turned into the soil with the last ploughing. The surface is reduced by the operation of the harrow when it is ready for the seed. But in Suffolk, where carrots are extensively raised, the land receives no preparation till the period of sowing.

Sowing, &c.—Of the different varieties of the common carrot, *daucus carota* of Linnæus, the orange carrot, which is of a darker colour, sweeter and more juicy, and grows to double the size of the pale yellow kind, is generally preferred for field culture. It is of great advantage to the agriculturist to raise his own seed from the best shaped roots of the preceding year's growth, by which practice he is certain of fresh seed of a good quality.

For the purpose of distributing carrot seed equally, it is usual to mix it with sawdust, bran, ashes, dry earth, or sand. The quantity of seed employed is from five or six to ten lbs. to the English acre. The time of sowing is about the middle of March, but it should not be delayed beyond the beginning of April. The early sowed crop is generally found to be the most productive. Mr Burrows of Norfolk, who cultivates carrots to a great extent, mixes the seed which he allows to the acre, from eight to ten lbs., with about two bushels of sand, or fine mould, a fortnight or three weeks before the time of sowing. The heaps formed of the mould and seed are daily turned over, and sprinkled with water, that the vegetation may be equally promoted. By this previous preparation the plants soon appear above the ground, and are less liable to be choked with weeds of a quicker growth.

Carrots are very generally sown broadcast, and the seed is covered in by means of a light harrow. Sometimes drilling is adopted, and the rows are from twelve to eighteen inches distant; and as the nature of the seed scarcely admits of the use of the drill machine, small furrows are formed by the hoe or other convenient implement; the seed is cast over the ground by the hand, and covered in by slight harrowing, or hoeing.

After-management.—The first hoeing, which is required in five or six weeks from the time of sowing, is performed with hoes four inches long and $2\frac{1}{4}$ inches wide; the second, with a six-inch hoe, and of the same breadth as the first, commences nearly as soon as the first hoeing is completed. The carrots are thinned out to the proper distance, which is from nine to 18 inches. A third hoeing is given some time in June, and it may be necessary to repeat the operation, if a new growth of weeds require it.

Preservation of carrots.—When the tops of the carrots become of a yellowish colour, and lose their freshness, they are ready for being taken up, which is generally the case towards the end of October; and as the tops, as food for live-stock, are of considerable value, the digging should not be delayed long, otherwise the quantity is greatly diminished. Carrots are either taken up by means of the plough, or by loosening the soil with three-pronged forks, and drawing up the plants by the tops. The latter method is considered the best. The tops are cut off, and laid in separate heaps; the roots are also heaped up, and allowed to remain in the field for two or three days; they are then removed, and packed up in heaps with dry straw, and, to protect them completely from the frost, they are thatched over with the same material. In whatever way carrots are preserved, they should not be put up too closely together, or in large quantities, as they are apt to be injured by heating, especially if they are not perfectly dry when they are laid up.

Some agriculturists dig up in the autumn a sufficient quantity to supply the live-stock during a lengthened period of frost or snow; the remaining part of the crop is left in the ground; and it appears that the carrots are more relished by the animals when drawn fresh from the soil. In March the whole is taken up to clear the land for the succeeding crop; and such part as is intended to be preserved through the months of May and June, should be examined about the end of April; the crowns of the healthiest and most perfect roots should be cut completely off. The carrots are then separated and laid by themselves, and in this way may be preserved through the month of June.

Produce.—The produce of the carrot crop is from 200 to 350 bushels from the acre of land, of a poorer and middling quality; but 800 bushels have been obtained from a rich soil in good condition. The expence is stated by Mr Burrows, who, in a period of four years, had 49 acres under this crop, at ten guineas the acre for the first three years, and about eight guineas the acre the last year. The estimated profit amounted to nearly L.28 the acre for the first three years, and for the last year the crop of 25 acres was valued by arbiters to the succeeding tenant, and the price fixed afforded a profit of nearly twelve guineas from each acre. These statements afford ample evidence of the value of a carrot crop, where the soil and situation admit of its culture.

Consumption of carrots.—The application of carrots in feeding farm-horses, seems, from their nutritious quality, peculiarly beneficial. Mr Burrows supports his horses solely on this root, conjoined with a suitable proportion of hay, through the winter and spring months; and he finds that they are in the same good condition, and equal to the same quantity of labour, as when they were fed on the full allowance of corn. Seventy pounds weight of carrots is allowed to each horse daily on an average; the proportion is smaller in the short days of winter, and larger in the spring months. The carrots are sometimes sliced down and mixed with cut chaff or hay, and at night they are given to the horses whole, with a small quantity of hay in the rack.

Carrots are greatly relished by all kinds of cattle. They are an excellent winter and spring food to cows giving milk; it is found that the quantity of both milk and butter is increased without any diminution of the flavour; and in fattening live-stock they are not less beneficial. In the application of carrots, with the same view, as the food of sheep, the produce of one acre has been estimated to be equal to that of two acres and a half of turnips,—an advantage which must surely afford full compensation for any extraordinary labour and expence in the culture. Hogs also become fat on carrots, when prepared by boiling; and as poultry are extremely fond of this root when it is subjected to the same preparation, it has been suggested that they might be advantageously fattened with it.

Arable land.

Sect. III. *Of the Rotation of Crops.*

It is now well understood in every district of the kingdom which the improvements of modern agriculture have reached, that land from which the same species of crop is taken successively for a number of years, is sooner and much more exhausted, with the same management, than if an equal, or even a greater number of crops of different species were raised from it, provided no two crops of the same kind shall immediately follow each other in the succession. To render this intelligible to the reader who is unacquainted with practical agriculture, let it be supposed that a farm, consisting of 100 acres, is divided into four lots, and that each lot is destined to produce the same crop for four successive years; as, lot first to have turnips; lot second, barley; lot third, clover; and lot fourth, oats; the whole of the land would be in a much worse condition with regard to its fertility, and the produce would be far more scanty at the end of four years, than when a single crop only of each species is taken from each lot during the same period. The lots which are limited to the production of four successive corn crops would approach to a degree of sterility, from which it would require a long period of the best after-management to recover them. Hence it is obvious, that the selection of the proper kinds of crops, and the order of their succession, form a very essential part of every judicious and profitable sytem of husbandry.

The learned Professor of Agriculture in the University of Edinburgh observes, that it is an important inquiry, how the kinds of produce best adapted for different situations, soils, and purposes, should be selected and assorted, so as to obtain, at the cheapest rate, and with the most certain success, those which are the most advantageous, and best correspond with the nature of the land and the husbandman's means of raising them, keeping in view general economy and profit, and the full supply of manure requisite to support the fertility of the soil. In every system of management, a remark made by the same author should never be forgotten, namely, "that it is always more easy to augment the fertility of any soil in proportion as it is already fertile; or, in other words, it is more difficult to raise the fertility of land from the pitch of bearing five bolls to that of seven, than from seven to nine, or even ten."

Arable land.

"The circumstance of any situation alone can determine," it is farther observed by Dr Coventry, "what are the most proper species of crops for culture; the best proportion in which the different species should be cultivated; and the best order or succession, with respect to one another, in which they should be raised. Certain particulars, in different cases, require the attentive consideration of husbandmen, when about to settle the mode of culture for their arable fields; some of them are of general import, and others more connected with particular or separate possessions.

"1. The general circumstances which require attention in fixing a rotation or course, are, the character of the climate;—the general nature of the soil;—the acquisition of manure, and particularly whether any extraneous supply of putrescent manure can be obtained;—the markets as more or less distant, or as adapted for the disposal of some articles of produce more than others;—and the kind of husbandry followed in other parts of the cultivator's own land, or the general husbandry pursued by him and that pursued in the district at large, so far at least as it may concern his interest, or affect his own scheme; in order that the whole might form one rational, consistent, and united system of husbandry.

"2. Those particulars which are more connected with the management of separate possessions and fields, are,—the advantages of having at suitable times, and of managing in a proper manner, a herbage crop, such as grass, clover, &c.;—the expediency and advantages of cleansing the land of weeds, either by a fallow, with the loss or with the delay of a crop, or with the substitution of one crop for another, or by a hoed crop, otherwise called a fallow crop;—the benefits which attend the raising of crops best adapted to the nature and state of the land;—the propriety of raising the crops most suitable to the condition of the manure;—the benefits that arise from causing the manurings and the cleansing process to correspond in the times when they are performed, and of making the endurance of the herbage crops, and the length of the whole course, such as will suit with these operations, and accomplish this purpose;—the advantages of raising different species of corn and other crops, to divide his labour, and insure more success otherwise;—and the advantage of regularity in cropping, and in the general arrangement of the labour." *Introductory Discourses*, p. 94.

Keeping these particulars in view, the next object of the husbandman is to institute a comparison of the different schemes of culture and cropping, that he may discover how far the latter correspond with the rules which may be deduced from a consideration of the former; for it is only by understanding fully the peculiar advantages of such courses, as well as the disadvantages which are attached to them in certain cases, that he is able to determine what are the most beneficial rotations in increasing his profit, and in improving the soil. Every scheme, then, for the cultivation and cropping of arable land, ought to be formed after fully considering the labour of cultivating the different species,—the manure required for the species of which the course is composed, as well as the quantity which each species is capable of returning,—and the price which the different kinds of produce bring in the market. Such are the rational principles which ought to be adopted in regulating the succession or rotation of crops, and which undoubtedly deserve the most attentive consideration of every judicious agriculturist.

Arable land.

General rules.—In arranging any system of rotation, it has been properly remarked, that no invariable rules can be given which are adapted to all cases, because a great deal depends on the soil, situation, climate, and other circumstances. The material points to be regarded appear to be those of properly suiting the crops to the nature and state of the lands, but especially that of interposing green or root crops between white or corn crops, or the strict observance of what is called the *alternate* husbandry; from which management, ample experience has shewn that while the land continues the shortest time possible unproductive, its fertility is least exhausted. In this way the culture of the field approaches to that of the garden, and the impoverishing effects of an uninterrupted succession of grain crops are avoided, while the amount of produce is greatly increased. But it ought to be observed, that the fertility, even of the richest lands, cannot be retained by a constant course of alternate cropping; and such management on sandy soils, and those of a lighter description, is altogether inadmissible. For the purpose of keeping up the requisite degree of fertility of such lands, that portion which has produced a herbage crop, is allowed to remain in the state of pasture for one or more years. According to this system, which is denominated *convertible* husbandry, the same land is, during one period, under arable management, and during another in the state of pasture. It may be adopted as another general rule, that the same kind of crop should not be repeated at too short intervals. If, for example, the same grain crop, as wheat, were taken from the same land every second year for any considerable period, the quality and produce would be greatly diminished. The recurrence of green crops on the same land, and in the same rapid succession, subjects them to a similar diminution in the quality and produce.

Proportion of green and corn crops.—It has been recommended by the author of the Survey of Middlesex, that where the land is of the best quality, an alternation of green and white, or corn crops, may be pursued; where the land is of a full medium quality, three green crops, and two corn crops, should be taken; but for ordinary land, the proportion should not exceed one corn crop for two green crops; and for poor exhausted land, as that of the Down and Sheep-walk description, one grain crop is sufficient for three green crops. By cropping in this manner, and in the proportions now stated, it is supposed that lands may be preserved in a clean state, and in a proper degree of fertility; and it is added by the author, that "under such management, they might be continued in perpetual aration, with a constant succession of large products." According to the proportions now stated, the four following rotations are suggested: I.—1. corn; 2. clover; 3. pease; or, 1. pease; 2. beans; 3. corn. Here there are two green crops for one of corn. II.—1. corn; 2. clover; 3. tares; 4. turnips; or, corn, clover, peas, and beans; which makes four crops in three years, and three green crops to one of corn. III.—1. tares; 2. potatoes, or cole, for sheep-feed; 3. turnips; 4. corn; 5. clover; which makes five crops in four years, and four green crops to one of corn. IV.—1. pease; 2. beans; 3. corn; 4. clover; 5. tares; 6. turnips; which makes six crops in five years, and five green crops to one of corn.

Rotations on different soils.—In cases where the convertible husbandry is pursued, and horse-hoeing is practised, and the green crops, as turnips, pease, and beans, are sown in double rows on three feet ridges, the following rotations are suggested by Mr Close for different soils. On clay soils, 1. turnips or cabbages; 2. oats; 3. beans and clover; 4. wheat; 5. turnips or cabbages; 6. oats; 7. beans and vetches; 8. wheat. On clayey loams, 1. turnips or cabbages; 2. oats; 3. clover; 4. wheat; 5. turnips or cabbages; 6. barley; 7. beans; 8. wheat. On rich or sandy loams, 1. turnips and potatoes; 2. barley; 3. clover; 4. wheat; 5. beans; 6. barley; 7. pease; 8. wheat; and, 1. beans or turnips; 2. barley; 3. pease or clover; 4. wheat; 5. wheat or potatoes; 6. barley; 7. pease; 8. wheat. On peaty soils, 1. turnips; 2. barley; 3. clover; 4. wheat; 5. potatoes; 6. barley; 7. pease; 8. wheat. On a chalky subsoil, 1. turnips; 2. barley; 3. clover; 4. wheat; 5. potatoes; 6. barley; 7. pease; 8. wheat. On this last rotation it is remarked, that ten acres in each hundred should be laid down with sainfoin for eight or ten years. On gravelly soils, 1. turnips; 2. barley; 3. clover; 4. wheat; 5. potatoes; 6. barley; 7. pease. On light lands, 1. turnips; 2. barley; 3. 4. and 5. clover and ray-grass; 6. pease; 7. wheat or rye; 8. wheat. But although we have detailed the above as a systematic view of rotations recommended for different descriptions of soil, it can scarcely be doubted that some of them are faulty when compared with the rules of good husbandry, and particularly in the frequent repetition of corn crops, sometimes in immediate succession, and in the entire exclusion of fallows, which, it may be justly apprehended, cannot be altogether dispensed with in every kind of soil and situation. In many cases, indeed, the fallow, or horse-hoed crop, may be a sufficient substitute.

In East-Lothian.—The following rotations are pursued in East-Lothian, a district of Scotland where agriculture has reached a high degree of perfection. On lands near the coast, where the soil is a dry gravelly loam, a four-course shift is adopted: 1. turnips, with or without manure; 2. barley, or spring wheat, with grass-seeds; 3. clover, used green for live-stock, or cut for hay; 4. wheat, or oats, if wheat was taken before, manured on the clover ley. On this description of land the turnips are consumed on the ground by sheep; or, what is considered an improvement, a proportion of the turnips is drawn, and carried home for cattle, or eaten by sheep in a contiguous stubble or grass field. Alternate drills are taken out, which is thought the best mode; and in some cases five or six drills are removed, while an equal number is left. By this management the turnip field is less injured in a wet season, and a greater quantity of land is manured. In deeper loams, with a dry bottom, the rotation practised is, 1. turnips; 2. barley, or spring wheat; 3. grass; 4. oats; 5. beans, drilled and horse-hoed; 6. wheat. The manure is only once applied, and is given to the turnips in this rotation, so that it requires the land to be of the best quality. On heavy loams, with a retentive subsoil, 1. fallow, with manure; 2. wheat; 3. beans drilled and horse-hoed; 4. barley; 5. clover, which is manured on the stubble; 6. oats; 7. beans, drilled; 8. wheat. The application of manure twice in the course of this rotation is found very beneficial. On the same kind of soil, the following rotation is also followed: 1. fallow, with manure; 2. wheat, with grass seeds; 3. pasture, eaten by sheep; 4. oats; 5. beans, sometimes mixed with pease, drilled; 6. wheat or oats. In this six-course shift manure is once applied, but the quantity is more liberal; and the pasture succeeding the second year after the fallow, and eaten off by sheep, is a compensation for the second application; and if the wheat be drilled, the rotation may be repeated without a fallow. On thin clays, 1. fallow, without manure; 2. oats, with grass seeds, or, if the fallow was manured, wheat; 3. pasture; 4. oats; 5. beans, manured; 6. wheat. On the poorest clays, 1. fallow, manured; 2. barley or oats, with grass seeds; 3. clover; 4. oats.

The rotation practised on land which is partly a black sandy loam on retentive subsoil, and partly sandy loam on dry sandy undersoil, and in the vicinity of Edinburgh, which affords the double advantage of a ready market for the whole of the produce, and an abundant supply of extraneous manure, is the following, 1. potatoes; 2. wheat; 3. clover, cut green: or, 1. turnips; 2. wheat or barley; 3. clover, cut green.

Distribution of crops.—No precise rules can be laid down for fixing the proportion of any possession which should be occupied by the different crops. The quantity of land destined to each species of crop must be varied according to the soil and situation. But as the great object, in every well regulated system of husbandry, is to preserve the soil in good condition, and at the same time to derive from it the greatest quantity of produce which it is capable of yielding, a certain proportion must always be established between the extent of land allotted to corn and green crops; for if the former greatly exceed the latter, the quantity of manure obtained is deficient, and the fertility of the soil is soon diminished. According to Dr Coventry's statement, the return of manure from a corn crop little exceeds four tons; but the amount from herbage, or green crops, is rather more than six tons from the acre. To preserve land in a suitable degree of fertility, five tons of manure are requisite for each acre annually; and hence it is obvious, that an average proportion between the two kinds of crops must be maintained. The deviations from this average may be more or less extended according to local circumstances.

Chap. VII. Of Grass Lands.

Some kinds of land, from peculiarities of soil and situation, are better calculated for grain crops than

Grass lands. those of grass; others are more suitable for raising grass than corn crops; and others still are better adapted to the convertible husbandry, or the alternate system of corn and grass crops. Lands which are sufficiently dry, and which in their natural state produce only coarse plants, belong to those of the first description, and are found to be more productive in the state of tillage, than in that of pasture. But without specifying particularly those lands which are best adapted for grass crops, it may be observed, that loamy soils which are not too strong for the growth of turnips, are most suitable for the practice of convertible husbandry. They are capable of being changed from the state of tillage to that of grass, and the contrary, not only without injury, but with the most beneficial effects.

In this chapter we shall treat of Artificial Grasses, of Natural Grasses, of Laying down to Grass, of Meadows, of Haymaking, and of Pasture lands.

Sect. I. *Of Artificial Grasses.*

The introduction and culture of different plants, which have been distinguished by the name of Artificial Grasses, constitute one of the most important improvements in modern husbandry. Some of these plants form an essential part in every judicious rotation of crops, and contribute largely, by the abundance of green or dried food which they afford, to the support of live-stock. The plants of this description are, trefoil or clover, sainfoin, lucern, &c.

Red clover.—Red or broad clover, *trifolium pratense*, is a well-known plant, which is successfully cultivated on all the better descriptions of dry land, which are in a tolerable state of fertility. It is sown with any clean grain crop; but when the nature of the soil admits, it succeeds best with barley after turnips.

Seed and sowing.—Fresh and well ripened seed, which smells sweet, has a bright appearance, and is of a purplish colour, should always be selected. On rich clean soils, 10 or 12 pounds are sufficient for the acre; but on less fertile soils of a stiff quality, 16 or 18 pounds are required; and a larger proportion must be allowed when the land is to be under pasturage for two or more years. When it is to be cut for hay, thin sowing is recommended. Clover seed is sown in any of the early spring months, with crops of spring corn, or over the young wheat crop. In the later districts, where it might be injured by frost, it is a better time to sow it with the barley crop in April; and it has been recommended not to insert it till the barley is two or three inches high, which then derives some benefit from the soil being stirred by a slight harrowing. When it is cultivated with a drill crop, it is sown broadcast, when the grain is drilled, and covered in by slight harrowing. It is sometimes also sown before the roller, when the barley is a few inches high; sometimes it is inserted during the hand or horse-hoeing operations. By the use of the roller after the harrow, the particles of the soil are closed upon the seeds, and the surface is levelled, which renders it less affected by drought; and no greater quantity of land should be sown than can be immediately covered in.

When the land is intended for early pasturage, or where the object is hay, it is usual with some to sow ray, rib, and other similar grasses, with the clover; and in this way a more luxuriant herbage is produced, especially on the later kinds of soil; but when the clover is to be cut green, for the purpose of soiling animals, it is the best method to sow it alone. Grass lands.

After-management.—The clover crop, on a good and well prepared soil, requires little future attention. The young plants, while in the seed leaf, are sometimes injured by slugs and other insects. Early sowing, by which the plants become vigorous before the dry weather approaches, is the best method of avoiding this injury. When the grain is removed from the land, it is the practice with some to apply manure over the clover crop; but this application is only necessary when the soil is not in a fertile condition. When the clover is continued for two or more years, a thin covering of manure, in the spring or autumn season, is found beneficial. On dry soils, the manure is most advantageously applied about the end of February; but where the lands are soft and retentive of moisture, the early part of autumn is the most suitable. At whatever season the manure is applied, it should be in a state of minute division, and spread evenly over the surface. When the clover crop is to be mown in the following summer, 30 bushels of coal ashes distributed on an acre, about the end of January, renders it more luxuriant and abundant.

Application of clover.—Clover is either cut for hay, employed as green food for different kinds of live-stock, or fed down with cattle, sheep, or other animals. When the crop is intended for hay, it should be mown as soon as the heads are in full blow, and before they appear of a brown colour, and die away. The proper time is known by observing when the leaves at the bottom of the stems decay and drop off. Early cutting is recommended after these indications of ripeness appear; for when the crop stands long, the plants are greatly exhausted, and a considerable time elapses before they send up new shoots. The clover should remain as it is left by the scythe, or until the swaths are dried about two-thirds through, which, in a favourable season, requires about three days; and if the weather appear promising, they may be turned with rakes immediately after the dew is dissipated. If no rain fall, the clover is ready for cocking up the next morning, or on the fourth day after the dew is off, and it may be carried in as soon afterwards as may be convenient. If this operation be conducted immediately after the dew is exhaled, the leaves are sufficiently tough to resist the effects of handling; but when it is deferred to the hot time of the day, they become too dry, and are liable to be reduced to powder. Some expert haymakers obviate this inconvenience, by putting the rows into heaps, which is performed by gently rolling the swaths over with large forks, and laying them lightly into the cock. By this management the clover is preserved with less loss, and the hay acquires a better colour and finer flavour.

When a second crop is intended for hay, no cattle should be admitted into the field, that the clover may be in full blossom, and fit for the scythe about the end of August. The process of haymaking is conducted in the same way, and it should not be de-

Grass lands. layed later, to avoid loss of weight, and the risk of injury from heavy dews and the rainy season, before it be secured in the stack. The second crop is usually inferior to the first, both in quality, and in amount of produce, so that if hay be not greatly wanted, it is considered a better practice to feed it off with sheep or other animals, where the soil is sufficiently dry, than to make it into hay.

The soil and situation, but especially the season, as it is moist or dry, produces great variations in the amount of the clover crop. Two tons are supposed to be a medium crop for the first cutting; and for a period of 15 or 20 years, the average produce of an acre under this crop, in Middlesex, is estimated at 12 guineas. Clover hay is chiefly employed in feeding draught horses, and is supposed to afford a more nutritious food than any other hay, excepting that of sainfoin. This species of hay is not less useful in feeding milk cows, and in fattening oxen.

Production of seed.—When the clover crop is intended to produce seed, it is sometimes cut for a first crop of hay, and the seed is obtained from the second crop; but it is a better practice to eat it well down in the early part of spring, and till the end of May, by ewes and lambs, or other stock, for in this way the land is less exhausted, and in better condition for the succeeding crop, besides the peculiar advantage of early green food for the live-stock. The crop remains till the husks or blossoms become quite brown, and the seeds have acquired firmness. After being cut down, it is left on the field till it is dry and crisp, that the seeds may be fully hardened. It is then put up as before directed, and the seed is thrashed out in course of the winter. The operation of thrashing out the seed, as it is difficult to separate it from the capsule, is always expensive. Some kind of mills or machinery, it has been suggested, might be usefully employed in diminishing this labour.

Cutting green.—The greatest advantage is derived from the clover crop by cutting it in the green state, and conveying it to the stable and fold-yard, for the purpose of feeding horses and cattle. Applied in this way, it is asserted that the clover crop supports more than twice the quantity of stock than by pasturing or feeding off in the field, and the additional quantity of manure obtained is a full compensation for the expence of cutting and carriage. The remarkable difference between feeding clovers off on the land, and the practice of soiling this kind of crop, is very distinctly stated by Mr Kent: "The quick growth of this grass," he observes, "after mowing, shades the ground, and prevents the sun from exhaling the moisture of the land so much as it would if fed bare; consequently it continues to spring with more vigour, and the moment one crop is off, another begins to shoot up. Whereas, when cattle feed it, they frequently destroy almost as much as they eat; and, besides, bruise the necks of the roots with their feet, which prevents the clover from springing so freely as after a clean cut by the scythe. In hot weather, which is the common season for feeding clover, the flies too are generally so troublesome to the cattle, that they are continually running from hedge to hedge, to brush them off; by which it is inconceivable what injury they do to the crop. But when they are fed in stables and yards, they are more in the shade, they thrive better, and at the same time consume the whole of what is given them, without waste." Grass lands.

Pasturing.—The practice of feeding down, or pasturing clover crops, is, no doubt, in some cases, advantageous, especially where sheep husbandry is pursued; but it should be conducted with no small degree of attention, both to the crop and the animals themselves. Sheep are the best stock for feeding on clover; but on dry soils, calves, foals, and other light kinds of stock, may be occasionally admitted. Pigs thrive well upon clover; and ewes fed upon it afford a greater flow of milk, which renders it a valuable application in the practice of lamb-suckling. The fattening of sheep in April and May, may be profitably conducted by feeding them on clover; and the same practice may be continued in the autumn, till the turnip crop afford a full supply of food. But it should always be recollected, that no kind of stock should be admitted to the clover crop when the land is wet and soft, for otherwise it would be greatly injured by poaching.

Hoving of cattle.—Cattle and other animals, by feeding on clover when in a succulent state, and particularly when it is moist with rain or dew, suffer much, and are sometimes destroyed by the distension of the stomach. In this state, the animal is said to be *blown* or *hoven*. To obviate this affection, which seems to depend on the air evolved from a large quantity of succulent food greedily swallowed, it is recommended not to admit the animals into the field before the moisture has been exhaled from the plants. The remedies proposed for this disease are, a strong solution of salt and water; new milk and tar, in the proportion of about half an egg shell full; stabbing the animal with a sharp penknife in the flank, close to the hip-bone, so as to avoid wounding the intestines, and placing a quill in the orifice, to discharge the confined air; but a long flexible tube, introduced into the stomach through the gullet, affords the safest and most effectual relief, although difficult and troublesome in its application. In the early stage of the disease, a strong solution of ammonia or volatile alkali in water, is also a valuable remedy, by producing an immediate discharge of air from the stomach.

Trefoil, or black nonsuch.—This plant, *medicago lupulina* of Linnæus, is not only useful in permanent grass lands, but may be beneficially employed as an artificial grass. The stem is more slender, and the growth less luxuriant than common clover. It is sown with oats, or among the wheat crop in the spring, when it is to be succeeded by grain in the following season, by which means a good feed is obtained in the stubbles for stock in autumn, while they are left free for tillage in the spring. This plant affords good pasturage for cattle, but it is peculiarly calculated for sheep, either alone or mixed with clover, and with its use they are less liable to hoving. It is earlier than clover, and affords a supply of food after the turnip and rye crops are consumed.

Sainfoin.—Sainfoin, *hedysarum onobrychis*, is a useful plant on the lighter and thinner kinds of calcareous soils; affords a valuable green food in hilly situations; is equally beneficial for the purposes of hay and pasturage, and is less dangerous to the animals which feed upon it, by producing distension of the stomach. The lighter kinds of shallow soils are best adapted for the growth of sainfoin. The ground should be clean and fine for the reception of the seed. It succeeds well after turnips.

Seed and time of sowing.—The seed, selected from the best plants, should be sown fresh. The quantity in the broadcast method is from two to four bushels; in drilling, three bushels are considered sufficient. Early sowing is always advantageous; the latter end of February, or the begining of March, is a proper time in most cases. Sainfoin is sown with any of the spring corn crops, but the best method is with barley after turnips; and it is recommended by some, that only half the quantity of barley which is usually sown for a full crop should be employed. When sown over the wheat crop, it should be harrowed in, and afterwards rolled; and in all the lighter kinds of land, the use of the roller should not be omitted.

After-management.—Much of the success of this crop depends on the after-management. While some advise it to be cut for hay instead of being pastured, others think that it should be neither cut nor pastured till the autumn of the first year. The diversity of practice here recommended, may arise from a difference of the soil, and a greater or less degree of luxuriance in the crop. On rich soils, it may be cut without injury the first year; but on poorer soil it seems better to save the crop entirely, to allow the plants to spread and form a closer sward in the following season. But in all cases, in the succeeding summers a crop of hay is taken, and the after grass is fed down, but not too closely, with any kind of stock except sheep, till December. In the following autumn, sheep, as well as other stock, may be admitted upon the pastures, till they are well eaten down; but they ought to be excluded as early as possible in the beginning of the year.

Sainfoin attains its perfect growth about the third year, and it begins to decline towards the eighth or tenth, unless manure be liberally applied. Sainfoin leys are greatly improved by the application of manure in the latter end of the second autumn. Coal-ashes, peat-ashes, soot, in the proportion of 25 bushels to the acre, and malt-dust, are employed for this purpose. When the crop is well established in the soil, top-dressings of this kind, every third or fourth year, retain it in a state of vigorous growth for 10 or 15 years.

This crop is useful in its green state for all kinds of stock, although it is supposed that the flavour of cows milk is injured by it; but its most usual application is in the state of hay, which affords a very nutritious food for working horses, as well as other kinds of cattle. The hay harvest is conducted much in the same way as for clover. When it is full in blossom, no time is lost in cutting it down, and, by the usual management, it is ready for being put into the stack in a few days.

Preservation of seed.—In preserving the seed of sainfoin, the plants should remain on the land till the husks become of a brownish colour, and the seeds are plump and firm. The crop is then cut down, and remains in the swath till the upper surface is quite dry, when it is cautiously turned over, to prevent the seed from shaking out; and when the whole is perfectly dry and crisp, it is either thrashed out upon cloths in the field, or laid up in stacks till a more convenient time.

Lucern.—This plant, *medicago sativa* of Linnæus, may be profitably cultivated on the deeper, richer, and drier kinds of loamy, gravelly, and sandy soils; but the land should be in the best state of preparation for its reception. With this view, it is preceded either by fallow, or a hoed crop of turnips, carrots, or cabbages.

Seed, and time of sowing.—The seed of lucern is of a larger size, and of a paler colour than that of clover. The freshest seed should always be preferred. The quantity required in the broadcast method is from 18 to 20 pounds to the acre; but when drilled in rows of 12 inches distant, 10 or 12 pounds are sufficient; and in 9 inch rows, which are reckoned the most proper, from 12 to 16 pounds are necessary.

Early sowing, as in the end of March for the southern districts, and the beginning of the following month in more northern situations, is recommended. When the plants are to be raised in a seed-bed, the sowing should be as early as the frosts admit, that they may be fit for transplanting in August. Where the labour of weeding and hoeing the crop cannot be perfectly executed, the broadcast method of sowing may be adopted; but where suitable attention to keep the land in a clean condition can be bestowed, drilling at narrow distances should be preferred. The practice of transplanting can only be had recourse to on a limited scale, and where the soil is rich, that the plants may stand thin and regular, and may acquire a rich and vigorous growth.

The seed is sown either alone or with grain crops. In deeper and richer soils, less time is lost in procuring green food, and there is a greater certainty of obtaining a crop when it is sown alone; but sowing with corn, on lighter and more porous soils, affords the young plants some protection in their early growth; and, according to some, the ravages of the fly are in this way more effectually avoided. When lucern is sown with grain, the quantity of seed of the latter should be less than usual. Oats are considered a better crop to accompany lucern than barley, because it is not so apt to lodge, particularly when it is sown thin. After the grain is sown and harrowed in, the lucern seed is regularly distributed over the surface, and covered in with a slight harrowing. The depth should not exceed two inches. When the drill method is followed, the lucern seed is inserted in the same way immediately after the corn has been deposited. The distance of the drills is best regulated by the condition of the soil. On rich soils, equal distances of a foot is considered sufficient, while, on those of inferior fertility, nine inches only are recommended. The seed soon vegetates, appears in the course of a week, and in a short time spreads over the surface of the land. The sooner it acquires the rough leaf, it is less liable to be injured by the fly; but in very dry seasons, when the growth is slow, it is sometimes entirely destroyed; and if it be a single crop, the method recommended as the most proper, is to plough the land, and sow it again with fresh seed.

After-management.—When lucern is sown broadcast, little attention is necessary after the grain crop has been removed, except keeping all kinds of heavy stock from it; but, in a dry season, it may be fed a little by calves and other light stock. If grass appear after the second cutting, in the following year, it may be moderately harrowed in different directions, and the grass being collected, is removed from the land. This operation should be performed early in the spring; and in the succeeding years similar harrowings may be given in spring and in the end of summer. When drilled, the soil is loosened in the intervals, and hand-hoeing is required to extirpate the weeds; and these operations are continued, as often as may be necessary, during the succeeding years of the crop. When the soil is not sufficiently fertile, manure is sometimes necessary, and the best is well rotted dung; for other matters are apt to encourage the unnatural growth of grasses. While some recommend a slight covering of manure annually, in the spring season, others think it a better practice to apply about 20 tons to the acre every five or six years.

The culture of lucern is attended with great expence; but as it is one of the earliest artificial grasses, it is sometimes ready for the scythe about the end of May, or beginning of June, and in favourable soils it may be cut every five or six weeks during the summer. As lucern affords a nutritious green food, it is highly beneficial in soiling horses and cattle, especially in cases where those animals form a large proportion of the stock; and it is not less important in the soiling of cows and other kinds of cattle in the fold-yards, and in the feeding and fattening of oxen; but it ought to be recollected, that animals feeding voraciously on lucern in its green state, especially when it is moist, are subject to be *hoven* or blown, so that care is necessary to supply them with moderate quantities at a time. Lucern is sometimes preserved for hay; but the most profitable application of this crop is in its green state, for the purpose of soiling live-stock.

Some other plants, as the winter and spring tare, and different species of vetches, burnet, and chicory, are also occasionally cultivated for the purpose of green food for live-stock, or of being converted into hay.

Sect. II. *Of Natural Grasses.*

The attention of agriculturists has been less directed to the history and properties of natural grasses, than the importance of the subject demands. In the selection of the different grasses, the soil and situation best adapted for their culture; their character, as they are more or less hardy; their permanency in the soil, on lands which are to be continued in pasture; the amount of produce which they afford, and the quantity of nutritious matter which they contain, require to be taken into consideration. Many useful and curious facts have been established with regard to the natural history and nutritious properties of the grasses; but observations and experiments are still wanting fully to develope and ascertain the character and valuable qualities of that useful tribe of plants, to enable the husbandman to decide with certainty on the preference to be given to each species, in different soils and situations.

The remarks of Curtis, in his Practical Observations on British Grasses, and the experiments of Mr Sinclair on the comparative merits and value of the different species and varieties of Grasses, an account of which is given in an appendix to Sir Humphry Davy's Elements of Agricultural Chemistry, furnish some useful information. In Mr Sinclair's experiments, the different grasses were cultivated on spots of ground containing four square feet. They were planted or sown, and the produce cut, collected, and dried, in summer and autumn. To determine the nutritive qualities of the different species, equal weights of the dry grasses were acted upon by hot water till their soluble parts were dissolved; the solution was evaporated to dryness with a gentle heat, and the matter obtained carefully weighed. From the works now noticed, the following observations on the character and properties of some of the natural grasses are chiefly extracted.

Sweet scented vernal grass, *anthoxanthum odoratum*, is one of the earliest pasture grasses, and grows in almost all situations, but it is not very productive. It is eaten by horses, oxen, and sheep; but when other grasses are found in the same pasture, it is left untouched. The delicate flavour of hay is derived from this fragrant grass. The produce of an acre of a brown sandy loam, with manure, at the time of flowering, amounted to 7827 pounds, 3 oz.; 80 drs. of the grass, when dried, afforded $21\frac{1}{2}$ drs.; and 64 drs. yielded 1 dr. of nutritive matter. When the seed is ripe, the produce of an acre is 6125 lbs. 10 oz.; 80 drams dried give 24 drs.; and 64 drs. afford of nutritive matter $3\frac{1}{4}$ drs. The after math produce of an acre is 6806 lbs. 4 oz.; and 64 drs. afford of nutritive matter $2\frac{1}{4}$ drs.

Rough-stalked meadow grass, *poa trivialis*, is a productive grass, and well calculated for pasturage or hay. It is much relished by all animals. At the time of flowering, the produce from an acre of light brown loam, manured, was 7486 libs. 14 oz.; 80 drs. dried, afforded 24 drs.; and 64 drs. yielded 2 drs. of nutritive matter. The produce of the acre, when the seed was ripe, was 7827 lbs. 3 oz.; and 80 drs. dried yielded 36 drs.; and 64 drs. gave $2\frac{1}{4}$ drs. of nutritive matter. The produce of an acre of the after math amounted to 4764 lbs. 6 oz.; and 64 drs. gave 3 drs. of nutritive matter. In this case, the crop, when the seed is ripe, affords the greatest proportion both of hay and of nutritive matter.

Smooth-stalked meadow grass, *poa pratensis*, is a common grass in meadows, in dry banks, and on walls. It is eaten by oxen and horses, but sheep prefer other grasses which are found in the same pasture. At the time of flowering, the produce of an acre, on a mixture of bog earth and clay, was 10209 lbs. 6 oz.; 80 drs. dried, gave $22\frac{1}{2}$ drs.; and 64 drs. afforded $1\frac{1}{4}$ dr. of nutritive matter. When the seed is ripe, the produce amounted to 8507 lbs. 13 oz.; 80 drs.

Grass lands. dried afforded 32 drs.; and 64 drs. yielded $1\frac{1}{2}$ dr. of nutritive matter. The produce of the after math was 4083 lbs. 12 oz.; and 64 drs. gave $1\frac{3}{4}$ dr. of nutritive matter. From these experiments this grass is of least value when the seed is ripe; and from the superior value of the grass of the after-math, compared with that of the seed crop, it is well adapted for permanent pasture.

Darnel, or rye, or ray grass, *lolium perenne*, is preferred by sheep, in the early period of its growth, to most other grasses, but when the seed approaches to maturity it is rejected. The hay from this grass is said, from its peculiar qualities, to be well adapted to the feeding of race horses and hunters. At the time of flowering, the produce from a rich brown loam amounted to 7827 lbs. 3 oz.; 80 drs. dried afforded 34 drs., and 64 drs. yielded $2\frac{1}{2}$ drs. of nutritive matter. When the seed is ripe, the produce is 14973 lbs. 12 oz.; 80 drs. of the grass dried gave 24 drs., and 64 drs. afforded $2\frac{1}{4}$ drs. of nutritive matter. The produce of the after-math was 3403 lbs. 2 oz.; and 64 drs. afforded 1 dr. of nutritive matter. The greatest quantity of nutritive matter is obtained from this grass when the seed is ripe.

Meadow fescue, *festuca pratensis*, is an early, perennial, and hardy grass; thrives well in almost all soils, especially in rich meadows and pastures; produces a sweet herbage; affords excellent hay, and is highly grateful to most animals. At the time of flowering, the produce from a bog soil, manured with coal ashes, amounted to 13612 lb. 8 oz.; 80 drs. when dried, afforded 38 drs., and 64 drs. gave $4\frac{1}{8}$ drs. of nutritive matter. The produce, when the seed is ripe, was 19057 lbs. 8 oz.; 80 drs. when dried afforded 32 drs., and 64 drs. gave $1\frac{1}{2}$ dr. of nutritive matter. From these statements, it appears that this grass is most valuable when cut and dried at the time of flowering.

Meadow foxtail, *alopecurus pratensis*, is an early and productive grass, vegetates quickly, and grows very luxuriantly. It is more relished by sheep and horses than by oxen. It delights in a soil which is neither too moist nor too dry. At the time of flowering, the produce from a clayey loam is stated at 20,418 lbs. 12 oz.; 80 drs. when dried yielded 24 drs., and 64 drs. gave $1\frac{1}{2}$ dr. of nutritive matter. The produce from a sandy loam amounted to 8507 lbs. 13 oz.; 80 drs. dried gave 24 drs., and 64 drs. yielded 1 dr. of nutritive matter. When the seed is ripe, the produce from the clayey loam was 12,931 lbs. 14 oz.; 80 drs. dried afforded 36 drs.; and 64 drs. gave $2\frac{1}{4}$ drs. of nutritive matter. The after-math produce from the clayey loam was 8167 lbs. 8 oz., and 64 drs. gave 2 drs. of nutritive matter. In this case, the produce from the clayey loam is nearly $\frac{3}{4}$ greater than from a sandy soil, and the crop of the latter is also of less value.

Crested dog's-tail grass, *cynosurus cristatus*, is a useful grass in upland pastures, produces a thick, short turf, and affords a wholesome food for sheep. The South Down sheep, and deer, it is said, are very fond of it, but it is neglected by the Welsh breed of sheep. At the time of flowering, the produce from brown loam, manured, is stated at 6125 lbs. 10 oz.; 80 drs. when dried, afforded 24 drs., and 64 drs. gave $4\frac{1}{4}$ drs. of nutritive matter. When the seed is ripe, the produce amounted to 12,251 lbs. 4 oz.; 80 drs. dried gave 32 drs., and 64 drs. yielded $2\frac{1}{2}$ drs. of nutritive matter. Grass lands.

Meadow soft grass, or Yorkshire white, *holcus lanatus*, is a common grass in almost all soils; but it is little relished by cattle, and the hay made from it is also disliked. The produce of an acre of a strong clayey loam, both at the time of flowering and when the seed is ripe, amounted to 19,057 lbs. 8 oz.; 80 drs. at the time of flowering, gave, when dried, 26 drs., but when the seed was ripe only 16 drs.; and 64 drs. afforded, at the time of flowering, 4 drs. of nutritive matter; but when the seed is ripe $2\frac{1}{4}$ drs. The weight of nutritive matter lost by leaving the crop till the seed be ripe is nearly $\frac{1}{3}$ of its value.

Meadow cat's tail, or Timothy grass, *phleum pratense*, is readily eaten by all animals. It grows most luxuriantly in a rich deep loam. It is extensively cultivated, and in high repute, in the middle and northern states of America; but it is asserted by Mr Curtis, that it possesses no superior excellence to the meadow foxtail. At the time of flowering, the produce from a clayey loam amounted to 40,837 lbs. 8 oz.; 80 drs. dried afforded 34 drs., and 64 drs. gave $2\frac{1}{4}$ drs. of nutritive matter. At the time the seed is ripe, the amount of produce is the same: 80 drs. dried afforded 38 drs. and 64 drs. gave $5\frac{1}{4}$ drs. of nutritive matter. The produce of the after-math is stated at 9528 lbs. 12 oz.; 64 drs. of grass afforded 2 drs. of nutritive matter, and 64 drs. of the straws gave 7 drs. of nutritive matter; so that the nutritive qualities of the straw greatly exceed those of the leaves.

Cock's foot, *dactylis glomerata*, is readily eaten by oxen, horses, and sheep. The oxen continue to eat the straws of the flowers from the time of flowering till the seed is ripe. At the time of flowering, the produce from an acre of rich sandy loam is 27,905 lbs. 10 oz.; 80 drs. dried gave 34 drs., and 64 drs. yielded $2\frac{1}{4}$ drs. of nutritive matter. At the time the seed is ripe the produce is 26,544 lbs. 6 oz.; 80 drs. of grass afforded, when dried, 40 drs., and 64 drs. gave $3\frac{1}{2}$ drs. of nutritive matter; so that the weight of nutritive matter gained by leaving the crop till the seed be ripe is more than $\frac{1}{3}$ of its value. From a comparison of the value of the after-math of this grass, with that at the time of flowering, and when the seed is ripe, it appears that the greatest advantage is derived from it when it is closely cropped, either with the scythe or cattle; and, when managed in this way, it is regarded as a very valuable grass.

Creeping bent grass, or fiorin, *agrostis stolonifera*, is, in many cases, a very valuable grass, and was first brought into notice by Dr Richardson. It succeeds best in a moist climate, or on a wet soil; and on cold clay soils, which are unsuitable for other grasses, it grows luxuriantly; but in dry situations, and on light sands, the produce of this grass is greatly diminished, from which it appears that all soils and situations are by no means fitted for the culture of this grass, as has been loosely and indiscriminately represented. Moist and warm sheltered spots are probably the most appropriate for its vigorous growth. It is readily eaten by horses, sheep, and oxen. Presented in the state of hay to horses, along with common hay, no marked preference appeared; but in a green state it was preferred to hay, both by cows and horses. A very extraordinary produce has been obtained from a crop of this grass. In one case, on a damp stiff clay, four square yards, cut in the end of January, afforded 28 lbs. of fodder; in another case, the same space yielded 27 lbs. of grass. In a trial made of this grass by Lady Hardwicke, 23 milk cows, a young horse, and a number of pigs, were kept a fortnight on the produce of a single acre. A similar abundant produce has been obtained from this grass, in Ireland, where it was first cultivated, and in different places, both in the northern and southern districts of Britain. At the time of flowering, the produce from an acre of bog soil amounted to 17,696 lbs. 4 oz.; 80 drs. when dried yielded 35 drs., and 64 drs. gave $3\frac{1}{2}$ drs. of nutritive matter. When the seed is ripe, the produce is stated at 19,057 lbs. 8 oz.; 80 drs. dried afforded 36 drs., and 64 drs. gave $3\frac{1}{2}$ drs. of nutritive matter; so that the weight of nutritive matter which is lost by taking the crop at the time of flowering is nearly a fourteenth of its value.

Beside the natural grasses now enumerated, several other plants, which are the spontaneous productions of the pastures and meadows of this country, may be added to the list; as, hard fescue, *festuca duriuscula*, which grows luxuriantly in almost all situations; sheep's fescue, *festuca ovina*, a perennial grass, which appears on dry, sandy soils, and is a favourite food with sheep; float fescue, *festuca fluitans*, which grows in moist places, and sometimes even in the water, forms a constituent part of some celebrated meadows in England, and is greedily eaten by horses and cows; red meadow grass, *poa aquatica*, shoots up vigorously on the drained lands of Cambridgeshire and Lincolnshire, and not only affords rich summer pasturage for cattle, but forms the chief part of their winter fodder; water hair grass, *aira aquatica*, to which the fine flavour of Cambridge butter is ascribed, is generally found on the edges of pools and standing waters; hop clover, or hop trefoil, *trefolium procumbens*, grows in dry pastures and meadows, and is strongly recommended for laying down land to grass, for when mixed with red clover, on light soils, it affords excellent fodder; red perennial clover, or cow grass, or marl grass, *trefolium medium*, remains longer on the land than the common clover, and rises spontaneously on calcareous soils; white or Dutch clover, *trefolium repens*, thrives luxuriantly on dry, sandy, or loamy soils, and sown with red clover and ray grass affords excellent hay; rib grass, *plantago lanceolata*, which produces abundance of herbage on rich sands and loams, but doubts are entertained of its utility as a pasture grass, and therefore it seems to have fallen in estimation; and Yarrow, *Achillea millefolium*, grows in almost every kind of soil, is reckoned one of the most valuable pasture grasses, from its remarkable property of resisting drought in dry seasons, and is much relished by all kinds of cattle, especially by sheep.

Sect. III. *Of Laying down to Grass.*

The previous tillage of land which is intended for the reception of grass seeds should be conducted in the most perfect manner. As the seeds are small, the soil should be in the most friable state, either by the frequent repetition of the operations of ploughing, harrowing, and rolling, immediately after the insertion of the grass crop, or by the frequent interposition of green fallow crops. But beside this mechanical preparation of the soil, it is not less requisite that it should be in a high state of fertility, either by the liberal application of manure to some of the preceding crops in the rotation, or what is recommended as the best practice, to that crop which is immediately succeeded by the grass. It is not less useful that lands intended for grass should be perfectly free from all kinds of weeds.

The furrows and ridges of grass lands, where the soil is of a light, porous, and dry nature, may be entirely obliterated, and the surface rendered smooth and even, by which the future operations in the grass management are greatly facilitated; but in soils which have a tendency to moisture, ridges of 6, 8, or 10 yards broad, with slight furrows, may be formed.

The selection of the proper kinds of seed is a matter of great importance in laying down lands to the state of grass. The peculiar habits of the plants, and the soils and situations to which they are best suited, are to be taken into consideration. The requisite proportion of seed also demands some attention. A larger proportion is found necessary for lands which have been long in the state of tillage, which are in cold exposed situations, and which are intended for pasture. No precise rules can be given, with regard either to the kind or quantity of grass-seeds which are best suited to different soils. The following have been suggested by the most approved writers on this subject.

Clayey soils.—For such soils, the following kinds and proportions are recommended. Marl or cow grass 5 lbs.; trefoil 5 lbs.; crested dog's-tail 10 lbs; meadow fescue 1 bushel; meadow fox-tail 1 bushel; or if the three last cannot be got, meadow soft grass, or Yorkshire white 2 bushels; meadow cat's-tail or Timothy grass 4 lbs.; or meadow cat's-tail 4 lbs., and Yorkshire white 1 bushel. On heavy kinds of land, which is to be broken up in a year or two, from 10 to 14 lbs. of red clover may be added; but if they are to remain in permanent grass, marl or cow grass, from 4 to 6 lbs. and white clover 4 lbs.

Loamy soils.—The following proportions are recommended as suitable for such soils: White clover 5 lbs; crested dog's-tail 10 lbs.; ray grass 1 peck; meadow fescue grass 3 pecks; meadow fox-tail 3 pecks; Yarrow 2 pecks. Where the second cannot be had, ray grass 1 peck, rib grass 4 lbs; and as substitutes for the last three, meadow soft grass, or Yorkshire white, half a bushel, meadow cat's-tail or Timothy grass 4 lbs., marl or cow grass 5 lbs. On all dry soils, white clover 4 lbs., marl or cow grass from 4 to 6 lbs. and yellow clover, from 2 to 4 lbs.

Grass lands. For permanent pasture, white clover, marl, or cow-grass, and yellow clover, from 6 to 7 lbs. each, with ray grass one bushel.

Sandy soils.—On this kind of soil some recommend white clover 7 lbs.; trefoil 5 lbs.; Burnet 6 lbs.; ray grass 1 peck; Yarrow 1 bushel; or, instead of the last, rib grass 4 lbs., ray grass 1 peck. But on such soils, others, guided by experience, employ white clover and trefoil in the proportion of 5 lbs. each, with a bushel of ray grass, and the same quantity of collected grass seeds, to the acre.

Chalky soils.—For such soils the following quantities are recommended: Burnet 10 lbs.; trefoil 5 lbs.; white clover 5 lbs.; Yarrow 1 bushel, or in its place ray grass 1 bushel. Others advise, for the same kind of soil, rib grass 8 lbs., white clover and marl or cow grass each 4 lbs., and yellow trefoil 4 lbs.

Peaty soils.—The following proportions succeed well on this kind of soil: White clover 10 lbs.; crested dog's tail 10 lb.; ray grass 1 peck; meadow fox-tail and meadow fescue, 2 pecks each; Timothy grass 1 peck; or, in place of the second, fourth, and fifth, meadow soft grass 6 pecks, rib grass 5 lbs. marl or cow-grass 4 lbs.

Laying down land for the purpose of meadow, the following proportions are recommended for the moister kinds of soil. Meadow fox-tail and meadow fescue, each $2\frac{1}{2}$ pecks; crested dog's-tail and vernal grass, each $\frac{3}{4}$ peck; rough stalked and smooth stalked meadow grass, each $1\frac{1}{2}$ peck; white and red clover, each from 1 to 2 quarts: but for lands of a wetter description, the crested dog's-tail and smooth stalked meadow-grass, may be omitted. The prevailing grasses of the Orcheston meadow, near Salisbury, which has been long celebrated for luxuriant herbage, are chiefly common meadow grass, *poa trivialis;* marsh bent grass, *agrostis palustris;* meadow fox-tail, *alopecurus pratensis;* but in speaking of grasses proper for meadows the fiorin ought not to be omitted, from which, in favourable situations, an abundant produce may be always expected.

Sowing grass seeds.—Grass seeds are sown in the spring, along with the grain crops, or in harvest, after the ground has been well prepared by means of some green or fallow crop. Some diversity of opinion prevails with regard to the preference which ought to be given to these periods of sowing. Each probably has its peculiar advantages, arising from the climate and situation, as the winter is more or less severe, and from the state of the soil, as it is more or less exposed to wetness. As land is always in a fine state of preparation for barley, this crop is peculiarly favourable to accompany grass seeds; and where a selection is permitted, that kind of barley which runs least to straw, and is earliest ripe, should be preferred. The equal distribution of the grass seeds is of great importance, so that the lighter kinds should not be sown in windy weather, except by means of a machine, which not only distributes the seeds uniformly and equally, but being surrounded by a kind of curtain, which protects the seeds from the action of the wind, the sowing process may be perfectly accomplished at all times. The seeds are covered in with a pair of light, short-tined-harrows. Bush-harrowing is improper, because the seeds are collected into thick patches. The use of a light roller, after harrowing the lighter and more porous soils, is beneficial. Grass lands.

After-management.—When the crop is removed, rolling with an implement of moderate weight is recommended, particularly for lighter soils. Some advise manure to be applied at the same time, but if the land be in a proper degree of fertility, this application is unnecessary; and it may be observed, that where top-dressings are at any time required for grass lands, the manure employed should be in such a state of division as to enable it to fall down among the plants, and mix immediately with the soil. When grass lands are intended for permanent pasture, early feeding down with cattle, or some kind of stock, for the purpose of producing a thick sward, is sometimes resorted to; but when this is judged necessary, if there be any risk of breaking the surface, and poaching the land, every kind of stock should be at all times excluded. Spring feeding with ewes and lambs is thought by some the most beneficial practice, and, in some places, feeding entirely with sheep is continued for the first two years. The mowing of such grass lands as are too moist to admit the treading of live stock without injury, greatly promotes the closeness and fineness of the sward; but the precaution should be attended to, of using the scythe, before the grass runs to seed.

Ant-hills, &c.—Ant-hills are injurious to grass lands, not only as occupying part of the soil, but by obstructing the operation of the scythe. The usual method of removing them is, by dividing the covering of sward into four parts from the top, and then digging to such a depth as to separate the whole nest of the insects, so that when the turf is replaced, it may be rather lower than the surface of the land. This renders the spot somewhat moist, and prevents the ants from returning to it. That part of the soil which is removed from the hillock, is either scattered on the field, or carried off to be mixed up with compost manure. Another method of destroying ant-hills is to cut them up in irregular lumps, and turning the grass side downwards till the mould be dry, and then exposing the surface to the air, till the whole be so dry as to burn readily. A fire is kindled with brushwood, and kept smothering, by gradually laying on the sods or lumps, till 10 or 20 loads of ashes are raised in one heap. In this way a nuisance is removed, and a valuable manure is obtained. Mole-hills are also extremely injurious to grass-lands; but this nuisance is generally removed by persons who practise the business as a separate profession, and who are well acquainted with the habits of the animal by which they are occasioned.

Sect. IV. *Of Meadows.*

Grass lands, which come under the denomination of meadows, are in low or moist situations, and are usually reserved for the production of hay. Such lands as may be profitably kept in the state of meadow, are in the vicinity of rivers or brooks, which admit of the essential improvement of irrigation, by which the amount of their produce is greatly augmented. Good meadow land should have a sufficient depth of soil, to prevent the roots of grasses to penetrate beyond the reach of the summer heat, and the soil should be sufficiently retentive to hold water long enough to encourage and promote the growth of the plants, while the under-soil possesses that degree of openness, to allow the water to pass off before the roots are injured.

In the management of meadow lands, the stagnation of water should be prevented, by which the growth of various noxious weeds is promoted, to the great injury of the herbage crop. Manure is applied to such lands at various intervals; in some places it is laid on in October, when the land is sufficiently dry to bear loaded carts; and in others, the application is made after the hay is removed. Rolling meadow land is highly beneficial; this operation is generally performed towards the end of February, or the beginning of the succeeding month, but it should never be had recourse to till the land be sufficiently dry.

Irrigation.—Great benefits are derived to meadow lands from the occasional and judicious application of water. Soils of a sandy or gravelly nature are the most suitable for this operation. Even strong adhesive soils are improved by watering, and lands which throw up coarse plants, as heath or rushes, are rendered more productive of useful herbage.

The verdure, luxuriance, and increased produce, which are the consequence of the occasional covering of grass lands with water, afford the most decided proofs of the beneficial effects of irrigation. Some of the advantages of this operation are to be sought in the enriching materials, whether of a vegetable or mineral nature, which are deposited by the water; but the protection of the roots of the grass and other plants, during the severity of the cold of the winter and spring, is stated as another advantage of floating the land. Sir Humphry Davy examined the temperature in a water meadow in Berkshire, and while the thermometer in the air at seven in the morning stood at 29°, and the water was frozen above the grass, the temperature of the soil among the roots of the grass was 43°.

The time of watering meadows is from November to the beginning of March. In some districts it is the practice to allow the water to flow for several weeks together, with an occasional interval of a day or two, while in others the flooding is performed by alternate weeks. The floating is usually suspended during frost, and as the spring advances the application of the water is diminished. The sandy, gravelly, and drier kinds of land require the flooding to be continued a shorter time than upon stronger soils. The duration for the first watering in November is from three to six weeks; in December and February the water should be allowed to flow off for a few days, and in the latter month it should not be permitted to continue many days together without being removed, that the danger of the scum settling on the surface may be avoided. Exposure to frost, when the ground is wet, is injurious; this inconvenience is obviated by removing the water in the day, and flooding through the night.

In the southern districts, the grass is usually sufficiently luxuriant in March to admit the feeding stock; but a fortnight at least should elapse after the water is turned off, that the ground may acquire a sufficient firmness before they are turned in. The grass may be eaten close in April, but no later, otherwise the hay crop may be diminished. The lands are again flooded in May for a few days after being fed down, by which means the produce of hay is greatly augmented. But for a fuller detail of the advantages of irrigation, and of the method of conducting the operation, the reader may consult Boswell on Watered Meadows; Wright on Floating Meadows; or Johnstone's Treatise on Draining and Irrigation.

Warping.—This is a provincial term for the operation of improving land, by admitting the tide waters of rivers near the sea, or of rivers with a slow current, in flat inland situations, for the purpose of depositing the earthy and organic matters, to which the name of *warp* is given, on the surface of the land. In conducting the operation of warping, the water must be completely at command, that it may be excluded or admitted at pleasure. The land to be warped is embanked against the river; a canal is formed which communicates with it, and has a sluice at the mouth, which is opened or shut as may be necessary. Another opening is made at the lower part of the warped land, to permit the water to flow gently off. This process must be extremely limited for the improvement of grass lands, for the quantity of matter deposited would soon cover and destroy the herbage crop. The object of the operation, it is properly stated, is rather to create a new soil; and this is sometimes effected in a single summer, from six to sixteen inches in thickness, and in all cases of a very fertile quality. The practice of warping usually commences in the month of June, and is carried on throughout the summer; in winter, and during the floods, the operation ceases. It is extensively prosecuted on the banks of the Ouse and Trent, and it may be adopted on all low lands adjoining to rivers, the waters of which are often loaded with mud.

Sect. V. *Of Hay-making.*

In determining the proper time for cutting grass crops intended for hay, attention is necessary to that state of growth and ripeness which affords the largest amount of produce, and at the same time the most nutritious fodder. Early and late cutting are equally to be avoided; as, in the one case, a great loss in drying, from the green condition of the crop, is sustained; and in the other, its nutritious quality is exhausted. The experiments which have been detailed in Section II. from which the quantity of nutritive matter, at the time of flowering and when the seed is ripe, is ascertained, may assist in fixing the most suitable time for cutting down the grass crop, by a reference to the comparative quantities of the whole produce, and of the nutritive matter which it contains at the different periods. Cutting down the grass crop should rarely be delayed beyond the time that it is in full flower; for when it is thick upon the ground, the lower leaves become yellow, induce a tendency to rotting, or communicate a disagreeable flavour; the seed stems become hard and wirey, and the produce of the after-grass is greatly diminished.

In cutting down the grass crop, the scythe should be kept perfectly level, and as close to the ground as possible, while the swaths are well pointed out, and scarcely any ridges are left under them. More attention is requisite in cutting the rowen, or second crop, because it is lighter. When it can be accomplished, crops of this kind should be cut when the dew is upon them, and as soon as there is a tolerable drought; for, by delay, the unfavourable weather retards the progress of hay-making.

Ray-grass and clover.—As the object of hay-making is not to bring the grass to that dry and withered state in which it would break and crumble down with the slightest handling, but to allow the superfluous moisture to be exhaled, which would be injurious to its preservation, when laid up in heaps, it is of importance that the different operations be speedily performed, and with as little exposure of the crop to the air as possible. Various modes of conducting these operations have been pursued. The following is found fully to answer the purpose. When the swath is thoroughly dry above, it is carefully turned over, without breaking or separating; and in favourable weather, the grass, which is turned over in the morning is put into cocks in the afternoon. This work is generally executed by women and children, under the direction of a superintendant. When the crop is heavy, a row of cocks is formed in the middle ridge of three, and if the crop be light, of five ridges. To every such number of ridges, a distinct number of carriers and rakers is appointed. The carriers collect the hay, and carry it to the ridge where the cock is built; a raker follows, raking up and bringing to the cocks the remainder of the swath. Five persons are usually required for each row of cocks, a carrier and raker on each side of the ridge, beside the builder; but when the crop is less weighty, as it is spread over a larger space, a greater number of rakers is necessary.

As the drying process proceeds, two or more cocks are formed into one, and the larger cocks may be speedily drawn together by ropes thrown round the bottom, and dragged along by a horse, for the purpose of being put into tramp-ricks. In some cases, the cocks were put up of such a size that they were carted directly to the stack-yard without being broken, and put up in alternate layers with old hay; but it is not safe to practise this method, where the proportion of clover is considerable. By mixing the new hay with the old, much time and labour are saved, and the old hay is greatly improved.

Another mode.—The method of making hay by what is provincially called *tippling* or *rippling*, first practised in Lancashire, has been introduced into the western districts of Scotland. The operation commences as soon as the crop is cut down. In making a tipple, a person with his right-hand rolls the swath onwards until he has a small bundle. The same is then done with the left till both meet, and form about eight or 12 lbs. weight. The bundle is set up between the feet; a rope is twisted of the grass, and tied round the rop of the bundle, and from the top are drawn a few straggling stems, which are twisted to give the tipple a conical shape. For a strong crop, a row of tipples is requisite to each swath; but when it is light, two swaths are put into one row. After standing a few hours, they become so smooth on the outside, that they are rarely wet through by the heaviest rains; and when they are wet, they are soon dried on the return of good weather. As soon as they are ready, they are put into the summer-rick, or if they are very dry they are carried directly to the winter stack; and as they are never opened out, or *tedded*, not a blade is lost, and the hay retains its green colour and rich fragrance. Hay put up in this manner is perfectly secure, although the duration of wet weather should be considerable.

Meadow-hay.—As the hay crop is of great importance on lands in the vicinity of the metropolis, where the consumption is large, much attention has been paid to the method of curing and preserving it. A very improved and successful system of managing this branch of rural economy has been introduced into Middlesex, and is minutely described by Mr Middleton in his Report of that County.

In the operations of the first day, all the grass cut before nine o'clock in the morning is tedded or spread out evenly over the whole surface of the ground. It is soon afterwards turned, and if the number of hands be sufficient, the whole is turned again before 12 or 1 o'clock. It is then raked into single wind-rows, at the distance of three feet; and the last operation of the day is to collect it into grass-cocks. Next day, all the grass that was cut the preceding day after nine o'clock, and all that is mown this day before that hour, is spread out; the grass-cocks are then shaken out into staddles, or separate plats of five or six yards in breadth. When the crop is thin, and the spaces between the staddles rather large, they are immediately raked clean, and the rakings are mixed with the other hay, that the whole may dry equally, and have a uniform colour. The staddles are next turned, and afterwards the grass which was tedded in the first part of the morning, once or twice, as on the first day. All these operations are executed before 12 or 1 o'clock, that the whole may be allowed to dry while the people are at dinner. The staddles are next raked into double wind-rows, which is done by every two persons raking the hay towards each other, and forming a row between them of double the size of the single wind-rows, which are at six or eight feet distant from each other. The grass is afterwards raked into single wind-rows; the double wind-rows are put into bastard cocks, and the single wind-rows are formed into grass cocks, which concludes the business of the second day. On the third day, the grass cut and not spread the day before, as well as that cut in the early part of this day, is spread out; the grass cocks are thrown out into staddles, and the bastard cocks into staddles of smaller extent. The narrow staddles, though last spread out, are first turned, then those which were in grass cocks, and last of all the grass is turned once or twice before 12 or 1 o'clock. In sunny weather, the hay which was last night in bastard cocks is this afternoon fit to be carried; and, if this be the case, the first operation after dinner is to rake that which was in grass cocks last night into double wind-rows, and afterwards the grass which was this morning spread from the swaths into single wind-rows. The hay which was last night in bastard cocks, is made up into full sized cocks. The hay

Grass lands.

should be raked clean, and the rakings put upon the top of each cock. The double wind-rows are then put up into bastard cocks, and the single ones into grass cocks, as in the preceding days. On the fourth day, the great cocks are mostly carried before dinner, and the other operations are similar to those of the former days; they are conducted in the same order, and continued daily, till the whole be finished.

For the purpose of abridging labour in the operations of hay-making, and of collecting the hay speedily together in bad weather, different implements have been invented. The hay-sweep is so constructed as to be drawn by two or four horses, according to its size, and is managed by two boys, one of whom, mounted on one of the horses, drives each pair. On level ground, nothing more is necessary than to break and turn up the rows of hay in different places, to allow the machine to operate; but when the ridges are high, and the surface unequal, the hay is raised by means of a fork, just before the machine, that it may catch and sweep it along. The hay-sledge employed in Yorkshire, is said to be a preferable machine, because it operates with more facility on uneven surfaces; and where there is a deficiency of hands, the hay-turner, invented by Mr Salmon, and described in the preceding chapter on implements, may be found useful in spreading and turning the hay crop.

Stacking hay.—In stacking hay, it is recommended to have staddles, by which the communication with the ground is cut off, and the access of moisture to the lower parts of the stack prevented. An oblong square is the best form; and about 24 feet by 14 or 15, is a convenient size. The business of stacking hay is best performed while there is a full sun especially in indifferent seasons, for in such circumstances it is greatly improved. To prevent the hay from heating, various contrivances, as holes, pipes, and chimneys, have been resorted to, for the purpose of allowing a circulation of air; but where it can be done, it is better to avoid such openings, as the hay round them is found to be injured by attracting the moisture of the stack.

Improved hay-rick.—Mr Chambers of Stratford Place, in a communication to the Board of Agriculture, has proposed a new method of constructing a hay-rick, by which the danger of hay taking fire, from being put up too green, is avoided, and other benefits are obtained. A channel or gutter, a foot wide, and a foot deep, is cut through the ground which is marked out for the rick, and two channels are cut transversely, dividing the rick lengthwise into three parts. Two chimneys, like the common hay funnels, reach to the points of intersection of the longitudinal and transverse channels. The channels are previously covered, except where the chimneys terminate. The chimneys are drawn up as the rick is built, so that they form a communication from the bottom to the top of the rick, and by means of the channels, from two points on each side, and from one at each end; and hence, from whatever quarter the wind blows, a constant current of air is kept up. The chimneys are thatched over when the heat subsides.

The advantages of this mode of construction are, that the hay may be carried a day earlier, by which it is less exposed to the weather; the expence of a day's labour is saved, the weight of the hay is greater, and the exhalations of moisture not being allowed to accumulate, the risk of the hay taking fire is obviated. Mr Chambers formed a rick of clover, consisting of 90 loads; and he thinks that 20 per cent of the present expence attending hay-making may be saved. It is recommended to construct corn ricks in the same way.

Agricultural thermometer.—When the danger of heating, or of actual combustion, is apprehended, the usual method of observing the changes of temperature is, by thrusting a stick into the stack; but, as the result of this experiment is vague and uncertain, the increase or diminution of heat can be precisely ascertained by means of a thermometer invented by Mrs Lovi of Edinburgh. This thermometer is so constructed, that it can be introduced into the stack, and the precise temperature discovered before it be withdrawn; and in this way the progress of the injury can be watched, and the necessity of turning over the stack distinctly indicated. If the temperature increase rapidly, and to a high degree, combustion may be dreaded, and the means of prevention must be expeditiously adopted; but if the temperature, after several trials at short intervals, shall appear to be on the decline, the labour and expence of opening up the stack may be avoided.

Sect. VI. *Of Pasture Lands.*

Under this head are included such lands as are retained in the state of grass for a limited time, and form part of the rotation with grain crops; such as are kept permanently under an herbage crop; and such whose inequality of surface, or elevation, precludes all tillage operations whatever.

The general directions, which are applicable to all pasture lands, refer to manuring in the way of top-dressing, when that is necessary; the extirpation of weeds; the removal of ant and mole-hills; the period of admitting live-stock in the spring, and of excluding them in the autumn; the quantity of stock introduced, and whether they should be all of the same or of different species; the advantages and disadvantages of feeding close, and the size and number of inclosures. In some of the best grazing counties of England, moderate sized inclosures are preferred; and Mr Marshall recommends, that in all cases where fattening cattle or dairy cows form part of the stock, and where situation, soil, and water permit, every suite of grazing grounds should consist of three compartments;—one for head-stock, as cows or fattening cattle; one for followers, as rearing and other lean stock; and the third to be shut up to freshen for the leading stock. A copious supply of water in every inclosure is of great importance to every kind of stock; and, in the formation of drinking pools, the attention should be directed to construct them in such a manner, that there may be no danger of young animals falling into them. The time of opening pastures in the spring must be regulated by the progress of the season. Old pastures may be stocked earlier than new formed grass grounds. Different kinds of stock are recommended for the same pasture, because the herbage which seems to be disliked and rejected by one species is eaten up by another. Although the greatest injury to pasture grounds arises from over-stocking, yet close feeding is, in many cases, advantageous, not only in preserving a fine close sward, but also in keeping down the coarser herbage, which otherwise might soon exclude much of the sweeter kinds of grass.

The general management of hilly or upland pastures, which are too rugged or too elevated to be brought under arable culture, is directed to draining, inclosing, and sheltering; and it seems probable that much of the land of this description is susceptible of great improvement by these operations judiciously conducted.

Chap. VIII. Of Live-Stock.

The returns to the agriculturist are derived from the grain crops raised on the possession, the produce of the dairy, or from the animals reared and fattened for the market. Local circumstances, no doubt, usually regulate the extent to which these different branches of rural economy are carried. Where arable culture is practised, working stock becomes necessary; and the productions of the dairy, to a certain extent, and some portion of animal food, are consumed by the family and servants of the occupier. The addition of manure to the exhausted soil, is an essential requisite; and this can only be obtained from the consumption of straw and green crops by live-stock. To conduct the whole of this complicated arrangement, demands great attention; and no small degree of skill and sagacity is required in selecting the best breeds of animals, whether for the purpose of labour, of the dairy, or of fattening; in selecting such as shall afford the most ample returns at the smallest expence, and in directing the mode of feeding and management to the most abundant production of manure. Mutually aiding and dependent on each other, the combination of the different departments of rural economy, in such proportion and extent as the soil, situation, and demands of the market admit, undoubtedly holds out the best and most profitable system for the occupation of land. In the following sections we propose briefly to treat of the more important domestic animals connected with rural affairs.

Sect. I. *Of Horses.*

Among domestic quadrupeds, the extensive utility and various excellencies of the horse, entitle him to the preference; and in estimating the qualities which render him valuable for agricultural purposes, strength, hardiness, activity, and true draught, are the chief points of attention. These properties exist in the Lanarkshire or Clydesdale breed of horses, the Suffolk punches, and the Cleveland bays. The Clydesdale horse is remarkable for his strength, and is peculiarly adapted for hilly countries; the Suffolk punch-sorrels, so called from their colour, are considered as the best cart horses in England, and are well fitted for undergoing long continued labour; and the Cleveland bays, which are reared in Durham, Northumberland, and Yorkshire, are of large size and fine mould, and possess great strength and activity. The Highlands of Scotland, and the mountains of Wales, produce a peculiar kind of small horses called *poneys*, which are reared with advantage in these coarse pastures, are much esteemed for neatness of shape and agility of motion, and are extremely hardy and sure-footed.

Breeding.—Farmers sometimes find it advantageous to rear their own horses, because the animals, when they are accustomed to the climate and pasture, are less liable to disease. Breeding mares may be gently worked for the sake of exercise, and ought to be well fed, and kept in good condition at all seasons, otherwise their offspring is apt to be weak and unhealthy. It is of great importance that the foal be not dropt too late in the season. Foals may be allowed to run with the mothers till September or October, or even later, in a mild season. When they are weaned, they should be kept in a stable, with a low rack and manger. Sweet hay, after-math, green clover, bruised barley or oats, bran and barley dust, are the best kinds of food for young foals. Foals should be carefully protected from cold and wetness; but it is highly beneficial, in mild weather, to admit them for a few hours daily into a dry and sweet pasture, where water is in abundance, and easily accessible. By this management, the young animal acquires habits of gentleness and docility, is more easily trained, and submits more quietly to labour. A horse intended for breeding should not be employed in work till he is 4 years old; no stallion ought to be kept for this purpose beyond the age of 18, and no mare should be allowed to breed after that period. Some experienced breeders are of opinion, that colts castrated at the age of three months, run less risk of inflammation than at a more advanced age; but, on the other hand, it is supposed, that by deferring the operation to the age of 18 months, or two years, the animals retain a greater degree of health and spirit.

Feeding.—The feeding of horses must always be an important object. Experience has amply shewn, that soiling with clover, tares, lucern, or other green food, instead of turning them out to grass, not only preserves them in the best condition, but is, at the same time, the most economical system of management. When they are well littered, the manure which is prepared almost repays the expence of their feeding. As winter food, carrots and Swedish turnip are cheap and excellent substitutes for oats. The use of carrots, it is said, is peculiarly beneficial in recovering broken-winded horses, provided the disease be not of too long duration. The best method of using grain for the food of horses is by bruising or boiling it; and hay or straw cut into chaff, potatoes, steamed or boiled, and mixed with a portion of bruised barley and barley-dust, are far less expensive than hay and corn, as winter food, while they are equally efficient in keeping them in good condition.

Stables.—Close stables, with separate stalls, where each horse can feed and repose without risk of being annoyed or disturbed, are recommended by some, while sheds with an open front, and furnished with

Live Stock.

a low manger and cattle rack, are considered by others as affording sufficient protection. During mild weather, and in a sheltered situation, this system of management is highly conducive to the health of the animals. They thrive better, are less susceptible of cold, are supposed to arrive at a greater age, and to continue longer fit for labour than when they are confined and shut up in warm stables.

Sect. II. *Of Cattle.*

The wild breed of cattle, which are now confined to Chillingham Park, in Northumberland, and Hamilton wood, in Lanarkshire, are supposed to be the origin of all the varieties which at present exist in Britain. The flesh of these animals is distinguished by its fine quality and exquisite flavour. This breed is remarkable for elegance and beauty of form; and, with the exception of the muzzle and extremity of the tail, the tips of the horns and hoofs, which are black, the colour is uniformly of the purest white.

The Devonshire breed is descended from this race. They are of a light red colour, have fine skins, are not large in size, but are hardy and well fitted for the draught, are not great milkers, but fatten early. The Hereford and Sussex cattle are nearly of the same colour, and possess similar properties, but afford greater abundance of richer milk. The Dutch or short-horned breed, which are much esteemed in the eastern counties of Britain, yield large quantities of rich milk and fine butter, fatten kindly, but are of a delicate constitution. The Lancashire breed is distinguished by long horns, thick hides, long close hair, coarse thick necks, and large hoofs; they are of various colours, but have generally a white streak along the back; they are of a hardy character; they milk sparingly, but the produce throws up a very rich cream. The celebrated Dishley breed is an improved variety of the Lancashire cattle. Their chief characteristics are, that they are smaller and cleaner boned, and fatten early and kindly, but the quantity of milk and tallow is deficient.

The Galloway breed, so named from the county in Scotland where they are chiefly reared, or the *polled* breed, as they have no horns, are in much repute among the English graziers, who annually purchase vast numbers for the supply of the markets of South Britain. They fatten well, and their flesh is of an excellent quality. This breed has been introduced into Suffolk, and are known by the name of Suffolk *duns*. The abundance and richness of their milk render them highly valued as dairy cows. The Dunlop or Ayrshire breed, so denominated from the name of the parish and county in which they were first reared, are supposed to be the offspring of Alderney cows and Fifeshire bulls. They are of small size, of a mixed red and white colour, and are more valued for the quality than the quantity of milk which they afford; but they continue to milk with little diminution, excepting about six weeks or two months, throughout the year. The Highland breed, or Kyloes, a hardy race, are chiefly reared in the Western Highlands, from which they are sent in vast herds to the southwards to stock the rich pastures of England, and to be fattened for the market, where the delicacy and flavour of their flesh have brought them into great demand. The Isle of Skye breed is a small variety of the kyloes, remarkable for its speedy fattening.

Live Stock.

Rearing.—In rearing live-stock of all descriptions, it ought to be an invariable rule to breed from small boned, straight backed, kindly skinned, round bodied, or barrel-shaped animals, with clean necks and throats, and little or no dewlap; and while the carcase is deep and broad, the least valuable parts, as the head and bones, should be small. In the selection of live-stock, such as have been accustomed to rich pastures should not be confined to those of an inferior quality, where they are apt to fall off, and occasion material loss. Animals of a quiet and docile temper, requiring less food, and being more easily fattened, ought to be preferred; and the valuable quality of early maturity, which is remarkable in some breeds, is too important to be overlooked. In the management of cows which are kept for breeding, it is to be observed, that about a month or six weeks previous to the time of calving they should be abundantly supplied with the richest kind of food. By this management, it is found that a larger quantity of milk is obtained than when they are fully fed for a longer period. For a day or two after the cow has drept her calf, her drink should be only lukewarm water, and she ought to be little exposed to cold or wet. The hardness of the udder may be removed by frequent milking, at least three or four times a day, and oftener if necessary, and by occasional gentle rubbing with soft ointment; but fomentation with flannel cloths, wrung out of hot water, and applied as warm as the animal will bear it, is probably a speedier and more effectual remedy.

Feeding and fattening.—Live-stock are supported by grazing in pasture lands; by *soiling* in proper yards or *sheds*, where they are supplied with luxuriant green crops; or by *stall-feeding*, where they are furnished with cabbages, turnips, and other food of a succulent nature, combined with various kinds of dry meat. When the grazing system is pursued, cattle should not be admitted into the pastures too early, or till the grass be so far advanced as to afford a sufficient supply of food. Much caution is necessary in changing the food of live-stock; and perhaps in all cases, even when it is of a richer quality, and more abundant in quantity, the change should be slow and gradual. A copious supply of pure water should always be within the reach of live-stock, as nothing contributes more to their health and vigour.

The advantages of soiling, or folding cattle in yards or sheds, which is strongly recommended by those who have practised it, are not yet, perhaps, fully appreciated. By this mode of feeding cattle, they are better protected, and less harassed with insects; the food is consumed with less waste; and when the yards are furnished with abundance of litter, as should always be the case, a large supply of excellent manure is obtained. But to have the fullest benefit from this mode of feeding, it is necessary to have convenient sheds and yards for the purpose; to provide suitable crops, in proper succession, to the proportion of stock; to conduct the feeding and general management of the animals in a clean and regular manner; and always to have a full supply of materials for litter. It ought not to be forgotten, that cattle managed in this way ought to have plenty of pure water, that they may have an opportunity of drinking whenever they are disposed; and it would, no doubt, be a most beneficial practice to turn them out into the open air for a few hours, in the cool of the evening in summer, or for a short time in the middle of the day when the season is colder. Varying the kind of food occasionally, when different kinds can be obtained, may be of considerable advantage.

For the purpose of fattening cattle in the winter, stall-feeding is resorted to. In this way they are kept more quiet and free from interruption, and feed more quickly, and with more regularity. The succulent kinds of food employed for this purpose are, turnips, potatoes, carrots, cabbages, grains, &c. and those of a dry description are, oil-cakes, oats, barley-meal, bean-meal, and other substances, with different kinds of straw, cut into chaff, by means of machinery. In stall-feeding, warmth and cleanliness are of great importance; and when both moist and dry food is employed, it should be combined in such proportions that the injurious effects of one species on the digestive organs of the animal, may be counteracted by that of another. The proportions of the different kinds of food must depend on the mode of feeding, the size of the animal, and the nature of the season.

Sect. III. *Of the Dairy.*

The situation of a dairy should be such that the lattices front the north, north-west, or north-east; and the lattices, which are preferable to glazed lights, may be covered with oil-paper, pasted on pack-thread, by which the light is admitted and the sun and air excluded. The utmost cleanliness is requisite in the whole management of the dairy; and, to attain this object, separate apartments, communicating with each other, are allotted for the reception and scalding of milk, for keeping and cleansing the vessels, and for making and preserving butter and cheese. The dairy should be paved with stone or brick, having a gentle inclination, and the pavement should be daily washed in summer. To preserve the air cool, it is recommended to have the dairy-house near a cold spring or rivulet, or by conducting a small stream of water into the apartments, to let it fall from some height on the pavement. The utensils, which are usually of wood, must be washed with the greatest care; or if metallic or glazed earthen vessels be employed, they ought to be daily scalded, scoured with salt and water, and well dried before the milk is poured in. Cast-iron vessels, glazed or enamelled in the inside, which are manufactured at the Shotts iron works, in Lanarkshire, have been lately introduced into the Scottish dairies, and are found to answer well, both on account of their cleanliness and durability.

1. *Making Butter.*

The quality as well as the quantity of a cow's milk, depends greatly on the nature of the food of the animal; but the quantity is also affected by the mode of milking. Much attention is necessary in managing this operation; and if any difficulty occur, the animal should never be treated harshly, by which the flow of the milk is diminished or interrupted. The hardness and pain of the udder, which sometimes produce this effect, are removed by fomentation with warm water, and gentle friction, and the flow of milk is restored. Cows are usually milked twice in the twenty-four hours; but in summer, three times a-day, at equal intervals, are necessary. The quantity of milk is thus increased, and the quality is not worse. The milk drawn from the cow is strained through a linen cloth or hair-sieve, into the cream-dishes, the depth of which should never exceed three inches. To remove the ill flavour which milk is apt to contract from the cows feeding on turnips, it is recommended to add 1-8th of boiling water to the milk before it is poured into the dishes. The ill flavour of milk, it is said, is also obviated, by boiling two ounces of nitre in a quart of water, and when cold adding a tea-cup full of the mixture to 10 or 12 quarts of milk from the cow.

Quality of milk.—The first drawn milk is thinnest, and of inferior quality. The cream which rises first is richest in quality and greatest in quantity. Thick milk affords the smallest proportion of cream, but it is of the richest quality. Milk diluted with water produces more cream, but the quality is injured. When milk is carried about in pails, or agitated and cooled before it is poured into the milk-pans, the quantity as well as the quality of the cream is diminished. From these facts, it appears of importance that cows should be milked near the dairy, to prevent the milk being carried and agitated; and it should be recollected that cows are hurt by being driven from a distance before milking. The practice of putting the milk of all the cows into the same vessel, before it is distributed into the milk-pans, is regarded as highly injudicious; both because the agitation and cooling are injurious, and because the quality of each cow's milk cannot be ascertained. If the milk of each cow were kept in a separate pan, the quantity afforded every day, as well as its peculiar qualities, would be easily determined. To have butter of a fine quality, the milk of all those cows which yield cream of a bad quality, ought to be rejected, and the last portion of the milk drawn only should be employed.

Churning.—The chief secret in the management of the operation of churning, whatever be the form of the apparatus employed, is to continue the agitation with the same regular, uniform, and uninterrupted motion, from its commencement to its termination; and to insure this uniformity, even the aid of an assistant, except in cases of absolute necessity, should be avoided; because too rapid or unequal motion, in summer, communicates to the butter an ill flavour, and in winter the process is interrupted or entirely fails. A table-spoonful or two of distilled vinegar, added to the cream, after it has been a good deal agitated, it is said, speedily promotes the separation of the butter.

When the butter is formed, it is usual to wash it in several waters till all the milk is separated; but it is better to squeeze out the milk by means of a flat wooden ladle with a short handle; or to spread it thin on a marble slab, and the remaining moisture may be easily taken up, by pressing it with clean, dry towels; and as washing with cold water injures the flavour, it may be cooled, and rendered sufficiently solid to retain the impression of the mould, by floating it in small vessels in a trough of cold water.

Salting.—Butter is usually preserved for future use by means of common salt. The following preparation, proposed by Dr Anderson, is an excellent substitute for common salt in curing butter, and imparts to it a richer and sweeter taste. Two parts of good common salt, one part of loaf sugar and one of saltpetre, are pounded and well-mixed together. One ounce of this mixture is well incorporated with every pound of butter, which is then closed up in a proper vessel, and at the end of two or three weeks, before which time it should not be used, it is fit for use. Thus prepared, it retains all its sweetness and flavour for two or three years.

The best and highest flavoured butter is made in summer; but it is said that a small portion of the expressed juice of the pulp of carrots, added to the cream before churning, communicates to winter butter the fine colour and rich flavour of what is made in summer.

Dutch butter.—The method of making butter in Holland is, to allow the milk, after it is drawn from the cow, to be cold before it is put into the pans; to prevent the cream from separating from the milk, by stirring it two or three times a day with a wooden spoon; and when it is sufficiently thick to churn it for an hour. When the butter begins to form, a quantity of cold water is poured in, for the purpose of separating the butter from the milk; and when the butter is taken out, it is washed and kneaded till the last water passes off pure. Milk managed in this way, it is said, yields a larger proportion of butter, which is firmer, sweeter, and keeps longer than by the ordinary method practised in this country; and the butter is also stated to be of a better quality.

2. *Cheese-Making.*

The excellence of cheese, it is not improbable, depends a good deal on the quality of the milk; but the season of the year in which it is made, and the management of the necessary processes, are not of less importance. The best season is from the beginning of May to the end of September, or, when the weather admits the pasture to be open, to the middle of October. In some large dairies the manufacture continues throughout the year; but winter-made cheeses are of inferior quality.

Rennet.—The rennet which is employed in coagulating milk is prepared with the stomach or *maw* of young calves. The curd found in it is thrown away; and after the bag has been steeped in pickle it is stretched out and dried, after which it will keep for a long time. An inch of the dried maw, steeped in a few spoonfuls of warm water the night before using it, will serve to coagulate the milk of five cows. But as the rennet by this simple preparation is apt to become rancid, greater attention is necessary to keep it in a sound state. The method of preserving it in the West of England is, when the rennet bag is cleaned, to make a strong solution of salt with two quarts of water; to add to this solution small quantities of all kinds of spices, and to boil the whole slowly down to three pints; then to strain the liquor and pour it on the rennet bag; to add a sliced lemon; and having stood at rest for a day or two, to strain it and bottle it for use:—when well corked, it will keep for a year, or longer, and communicate to the cheese a pleasant aromatic flavour. A decoction of the flowers of yellow ladies bed-straw, or cheese-rennet, *galium verum*, a common plant in many pastures, and muriatic acid, or spirit of salt, when judiciously managed, are successfully employed as efficient substitutes. The peculiar pungent taste of Dutch cheese is ascribed to the use of the latter substance in coagulating the milk.

Colouring.—Spanish arnotta is the substance in most common use for colouring cheese; and it is employed in different proportions according to the shade required. In Gloucestershire an ounce is allowed for every hundred pounds of cheese. The poorest cheese requires the largest proportion. The method of using it in Cheshire is to tye up the necessary quantity of pounded arnotta in a linen rag, and to infuse it in half a pint of warm water the night before it is wanted, and next morning, before the application of the rennet, to mix the coloured infusion thoroughly with the milk; or, as it is practised in some places, a piece of the unpounded arnotta, dipped in milk, is rubbed on a smooth stone, and the colouring matter thus obtained is combined with the milk in the same way.

Cheshire cheese.—The cream of the preceding evening's milk is skimmed off and poured into a pan heated with boiling water, and a third part of the same milk is heated in the same way. The new milk of the morning and that of the preceding evening being thus prepared, are introduced into a large tub along with the cream. The colouring matter first, and then the rennet, after the necessary preparation, are added. The whole is stirred together and covered up warm till it is curdled, is then turned over with a bowl to separate the whey, and soon after the curd is broken into small pieces. The whey is removed and the curd is cut into slices, and repeatedly turned over and pressed with weights to separate the remaining portions of whey. The curd removed from the tub is broken by the hand into small pieces, put into a cheese vat and strongly pressed, transferred afterwards into another vat, or returned into the same, after it has been well scalded, and the process of breaking down and pressure is repeated. The cheese is then removed into a third vat, previously warmed, with a cloth beneath it, and a tin hoop, or binder, put round the upper edge of the cheese and within the sides of the vat, the former being enclosed in a clean cloth, and its edges placed within the vat. The processes now described occupy a period of six hours, from seven in the morning till one in the afternoon; and eight hours more are necessary for pressing the cheese, during which time it should be twice turned in the vat. The succeeding morning and evening it is again turned and pressed, as well as on the morning of the third day, about the middle of which it is removed to the salting apartment, where the outside is well rubbed with salt, and a cloth binder is passed round it. During a week, while the cheese remains here, it is turned twice a day, and as it is left for some days longer to dry, it is turned once, and well cleaned daily. It is then transferred to the store-room, which should be moderately warm, and protected from a current of air, to avoid the risk of cracking, and turned every day till it become firm and dry.

Gloucester cheese.—In making Gloucester cheese the milk is used as it is drawn from the cow; and if it be too hot in summer, the temperature is reduced by adding skim milk, or water. After the application of the colouring matter and the rennet, the formation of the curd, and breaking down the latter with the hand and a double cheese knife to separate the whey, the curd is put into vats and pressed for a quarter of an hour. It is then turned into cheese tubs, and again broken small, scalded with a pail full of water, lowered with one part of whey, and the whole is briskly stirred. Having stood a few minutes to allow the curd to settle, the liquor is strained off, and the curd is collected into a vat. When the vat is half full, a little salt is sprinkled on and well wrought into the cheese; the vat is filled up; the whole mass is turned two or three times round; the edges are pared, and the middle rounded at each turning. The cheese, surrounded with a cloth, is again subjected to pressure, is then removed to the shelves, and turned daily, till it be sufficiently firm to admit of being washed.

Stilton cheese.—The method of making this cheese, as it is described in the Agricultural Report of Leicestershire, is the following: The night's cream is put into the morning's new milk, with rennet, and when the curd is come it is not broken, as is done with other cheeses, but taken out whole and placed in a sieve, to drain gradually, and as it drains, a gradual pressure is continued till it becomes firm and dry. It is then placed in a wooden hoop, and afterwards kept dry on boards, and turned frequently with the cloth binders round it, which are tightened as occasion requires. When the cloths are removed, each cheese is rubbed with a brush once every day, and in damp weather twice, for two or three months. The same thing is done daily to the tops and bottoms of the cheeses before the cloths are removed.

Cream cheese.—This kind of cheese is usually made in August or September, when the milk is richest. As the warmth of the season is insufficient to ripen it, a greater thickness is given to this kind of cheese, that it may retain its mellowness. In the preservation of cream cheeses, a warm situation should be selected, and the precaution of securing them from frost should be strictly observed, otherwise the rich quality of the cheese is lost, and it becomes insipid or ill tasted.

Dunlop cheese—Is so called from being made in a parish of the same name, in Ayrshire in Scotland. When the milk is brought to the temperature of 90° in summer, and above 100° in winter, it is poured into a large vessel, and the rennet being added, it is covered up closely for about ten minutes. With good rennet the milk is then coagulated, and by gently stirring it the whey separates, and is removed as it collects, till the curd become tolerably solid. The curd, placed in a drainer, is pressed down with weights; and having remained for some time till it is dry, it is returned into the first vessel, where it is cut into small pieces with a knife, composed of three or four blades, which cut horizontally. It is then salted and properly mixed by the hand, put into a strong dish with iron hoops, which has a cover that goes exactly into it; a cloth is placed between the curd and the vessel, and in this state it is subjected to the cheese-press, from which it is occasionally taken, and wrapped in dry cloths till the whey is entirely separated. The cheese is then laid aside for a day or two; and if, on examination, any appearance of whey remains, the pressure and application of cloths are renewed. The whey being extracted, the cheese is laid out on boards, which should be of the same breadth, or on a deal floor; and it should be occasionally examined, to remove any moisture that appears, turned occasionally, and rubbed with a coarse cloth, which may prevent the breeding of mites.

Parmesan cheese.—The process for making this celebrated cheese, which is a production of the rich dairies of Italy, is thus described: At ten o'clock in the morning, $5\frac{1}{2}$ brents of milk, each brent about 48 quarts, are put into a large copper, which turns on a crane, over a slow wood fire, made about two feet below the surface of the ground. The milk is stirred from time to time; and about 11 o'clock, when just luke-warm, or considerably under blood heat, a ball of rennet, of the size of a walnut, is squeezed through a cloth into the milk, while the stirring is continued. By the help of the crane, the copper is turned from over the fire, and allowed to stand till a few minutes past 12, at which time the rennet has operated. It is now stirred up, and left to stand a short time; part of the whey is taken out, and the copper again turned over a fire sufficiently brisk to give rather a strong heat, but below that of boiling. A quarter of an ounce of saffron is added to colour it, and the stirring is occasionally repeated. The dairyman frequently examines the curd, and when the small, and as it were granulated parts, feel rather firm, which is in about an hour and a half, the copper is removed from the fire, and the curd is left to subside; part of the whey is taken out, and the curd, brought up in a coarse cloth, is put into a hoop, and about $\frac{1}{2}$ cwt. placed upon it for an hour, after which the cloth is taken off, and the cheese placed on a shelf in the same hoop. At the end of two or three days it is sprinkled over with salt, and the same application is repeated every second day for about six weeks. During the process of salting, two cheeses are usually placed upon each other, in which way they are supposed to take the salt better than singly.

Keeping of cheeses.—Cheese should be kept in an airy situation. The leaves of tutsan, or park leaves, *hypericum Androsæmum*, or of the yellow star of Bethlehem, *ornithogalum luteum*, moderately dried, or the young twigs of the common birch tree, especially the latter, placed on the surface or sides of the cheeses, are found useful in preventing the depredations of mites. The *hoving*, or swelling of cheeses is ascribed to some imperfection in the process of making. Regular turning, and keeping such cheeses as have this tendency in a moderately cool, dry place, have the effect of interrupting or preventing its progress. When the swelling becomes considerable, it is necessary to prick it with an awl or pin in several places, by which the air evolved is allowed to escape.

Sect, IV. *Of Sheep.*

Sheep are a very valuable kind of live-stock, on account of the flesh, the wool, and other products. In many situations, the largest proportion, and in others the whole of the profits of the husbandman are derived from this kind of stock; and there are probably few possessions which may not afford some advantage in the view of breeding, grazing, or the fattening of their lambs.

The numerous breeds of sheep which are prevalent in this country, have been arranged into two classes; those which shear the short, or clothing, and those which shear the long, or combing wool. By others they have been divided into the mountain breed, the short-woolled, and the long-woolled breed. The first class includes the varieties which are reared in the mountainous districts of Wales, the north of England, and Scotland; the second comprehends those of Hereford, Dorset, Sussex, Norfolk, and some other places; and the last class embraces the varieties which occupy the richer and more fertile parts of England, and which are distinguished by the names of the Durham or Tees waters, the Lincolnshires and the Leicestershires.

Mountain sheep.—The mountain, heath, or, as they are sometimes called, black-faced sheep, from having black faces and legs, are a hardy active race, with large spiral horns and short firm carcases. They afford fine grained and well flavoured mutton, but the wool is open, coarse, and shaggy. They are usually fattened about the third or fourth year. The Cheviot breed has no horns; the face and legs are chiefly white, and the eyes are lively and prominent. This is a hardy race, affords fine wool, and is quick in fattening.

Short-woolled.—The Herefordshire sheep are small in size, have no horns, have white legs and faces, and fine short wool. This breed is also known by the name of *Ryelands.* They are remarkable for being patient of hunger, and it is said that no breed of sheep in the island can subsist on so small a portion of food. The South Down breed is also distinguished by the closeness and fineness of the wool; they have grey faces and legs, long small necks, and afford fine grained and well flavoured mutton. This is the prevailing breed in the dry chalk downs of Sussex. The wethers are rarely kept beyond the age of two years, and they are often fattened at 18 months. The Norfolk breed is distinguished by a black face, large spiral horns, and long black or grey legs; the wool short and fine, and the mutton fine grained and high flavoured.

Long-woolled.—The Lincolnshire breed, known also by the name of *Old Leicester,* is distinguished by want of horns, white faces, long, thin, weak carcases, large bones, slow feeding, coarse grained mutton, and wool from 10 to 18 inches in length. This breed thrives only on the richest pastures, and is chiefly valuable on account of the large quantity of wool. But it is from this breed that the *New Leicester,* or *Dishley* breed, which derives its name from the place where it was successfully reared and improved by the celebrated Bakewell, is descended. The Dishley breed is distinguished by its fine lively eyes, clean heads, without horns; straight, broad, flat backs; round or barrel-shaped bodies; small bones; thin pelts; a disposition to fatten at an early age, and fine grained, well flavoured mutton. The weight of the quarter, in ewes of three or four years old, is from 18 to 26 lbs.; in two year old wethers, from 20 to 30 lbs.; and the length of wool is from 6 to 14 inches. The excellence of this highly improved breed consists in their fattening more speedily, and with a smaller consumption of food than almost any other; in having a larger proportion of meat on an equal weight of bone; in thriving well in pastures which would not support other kinds of the same size; in more valuable wool; in being ready for the market early in the spring; and, from all these properties, affording a greater profit. The Tees-water breed have longer legs, finer bones, and a thick and firmer carcase, than the Lincolnshire; the mutton is fatter and finer grained, and the wool is shorter and less heavy. This is the largest breed in the island, and is the most common on the rich inclosed lands on the banks of the river Tees in Yorkshire, from which it has received its name. It seems to be only calculated for warm, well sheltered pastures, and requires to be well fed in severe winters. A large weight of mutton is obtained from this breed, but it is longer in coming to maturity, and requires a larger portion of food, so that it is less profitable than those of a smaller description. The Romney-marsh breed has no horns, has white faces and legs, which latter are long; the body rather long, but well barrel-shaped, and bones rather large. The wool is fine, long, and of a delicate white colour. This breed arrives early at maturity, and succeeds well on the richer kinds of pasture. In the *Merino,* or Spanish breed of sheep, the males have horns, but the females sometimes have none; the faces and legs are white; the shape of the body not very perfect, and the legs are rather long. It is fine boned, and the pelt is clear and fine. This breed is also well known to be remarkable for the fineness of its wool; it is also pretty hardy, and has a disposition to fatten readily. But for a detailed account of the different breeds of sheep, as well as for the general management, the reader may consult with advantage, Culley on *Live-Stock,* Parkinson on *Live-Stock,* and Dr Parry's *Memoir on Breeding and Feeding Sheep, in Communications to the Board of Agriculture,* Vol. V.

Sect. V. *Of Swine.*

Some diversity of opinion exists with regard to the benefit arising from the breeding and rearing of swine, conducted on a large scale; but of the advantage afforded by this kind of stock, when kept within moderate limits, and managed as a secondary concern, no doubt can be entertained. The expense of rearing and feeding swine to a certain extent is small, while the profit is considerable. It has been observed by a writer in the Farmer's Magazine, who has had much experience in rearing this kind of stock, that a farm of 300 acres, of which 200 are kept under tillage, might, by proper management in the rearing of swine, afford L.100 Sterling of annual profit. A very small capital is required in this branch of rural economy, and the trouble and expense which attend it are trifling. It is stated by the same writer, that it is the most beneficial stock which can be introduced on a farm, as long as the number kept exceeds not the extent of offals produced on the possession.

Numerous varieties of this animal are reared in Britain. The Berkshire breed is of a reddish colour, with short legs, large ears, and a thick, close, well-made body; is readily disposed to fatten, and grows to a large size; but the supply of food must be constant and abundant. The Chinese, or black breed, is of small size, short legs, and thick, close, well made body; is considered one of the most profitable breeds in the country; the flesh is delicate, and it fattens kindly, even on indifferent food. The Gloucester breed is of a white colour, and large size; is ill formed, and considered unprofitable. The Hampshire breed is also white, has a large body, fattens kindly, and attains a great size. The Highland, or Irish breed, is of small size, and ill shaped; is regarded as an inferior kind, for it thrives indifferently. The Northampton breed is remarkable for the enormous length of its ears; is of a large size, but does not fatten very kindly. The Rudgwick breed is reared at a village of the same name, on the confines of Surry and Sussex; is a valuable variety, fattens readily, and to a large size. The large spotted Woburn breed is a new variety, introduced by the late Duke of Bedford; the colour is various and the size large; it is well formed, prolific, hardy, and kindly disposed to fatten, attaining nearly twice the size and weight of other hogs within the same given period. The reader who wishes to have a full and satisfactory account of the method of feeding swine, and of curing pork and bacon, is referred to the *Complete Grazier*; or to Henderson's *Treatise on Swine*.

Chap. IX. Of Farm-offices, Leases, &c.

In concluding this treatise, a few general remarks on the situation and requisite accommodation of a dwelling-house and farm-offices, on leases and rent, may be useful.

Sect. I. *Of Farm-Buildings.*

Situation of farm-offices.—The situation and general arrangement of the necessary buildings of a farm-steading, have been oftener directed by accident than by attention to convenience or local advantages. When other circumstances admit, the most centrical situation on the possession ought always to be selected; but where a dry, sheltered, and healthy spot presents itself, and having, at the same time the command of abundance of water, for the purposes of domestic economy, or of driving machinery, some deviation from the general rule may be admitted. With regard to the general arrangement of the different buildings of farm-offices, it is recommended to select the three most exposed sides of a square for them, while the southern aspect is left open to the sun and air. While it is considered advantageous to erect the dwelling-house at a small distance from the offices, it may be equally beneficial to have the ordinary sitting-room so arranged as to command a view of the farm operations, both in the immediate vicinity and in the fields. The windows of this apartment should have a full view of the chief approach to the yards, cattle, &c. and when it can be accomplished, should also be directed to the farm-yard.

Farm-offices.—The judicious disposition of the offices of a farm, is a very important object of rural economy. Distinct buildings are necessary for the various sorts of cattle, and other purposes; and the general distribution and relative position of the whole, should be so arranged as to suit the convenience, and facilitate the labour of the attendants. The bottom of the yard should be quite level, and bedded with some substance which renders it impenetrable to water, that liquid animal matters may not be absorbed and lost. In erecting feeding-houses, or ox-stalls, their situation, which ought to be dry, and not too much exposed to the sun, demands particular attention. The floor should be paved, and have a gentle slope. The stalls are from seven to nine feet wide, according to the size of the animals. Cows require the same space, for the convenience of milking, and of suckling their calves; but the stalls should never be so wide as to permit the cattle to turn round in them, by which accidents sometimes happen. These may be obviated by placing a post in the middle of the stall, immediately before the shoulders of the cattle. A regular temperature, and a proper circulation of air, are preserved by means of windows furnished with shutters, which are opened or closed according to the state of the weather.

In the construction of stables, a dry airy situation should be selected, and the buildings should be furnished with shutters, to exclude the light in the day-time, when necessary. With regard to the pavement of stables, it is recommended to cover that part on which the horses lie down, with oak boards, arranged transversely upon a level, and pierced with holes, for conveying the urine from the stall-drain into the main-drain. The other part, paved with small stones, has a slope towards the perforated boards. The ordinary construction of mangers and racks is faulty and inconvenient, in allowing a needless and excessive waste of provender, and exposing the animals to injury, from hay seeds falling into their eyes and ears. The barn is an essential building on farms where corn husbandry is practised, which should be in a dry situation, with a firm dry floor, well ventilated, and sufficiently spacious for the extent of the possession, or the amount of the produce. A building for the reception of carts and implements which are not in immediate use, is also requisite, to protect them from the weather. A building of this description should be so contrived, as to afford complete shelter from the rain, while a free circulation of air is admitted. A smaller apartment should be appropriated for the numerous smaller tools and implements; and it may be added, that no implement should be deposited before being cleaned, dried, and completely repaired, so that it may be always in readiness for future use. The construction of calf-pens and piggeries, also merits attention; and where the feeding of live stock is extensively carried on, the commodious situation of the straw and root-houses, and of the necessary appendages of a steaming apparatus, should be particularly studied, in the view of saving time, and avoiding waste. The arrangement and management of the dunghill, which is always an object of the utmost importance, has been already described in the chapter on manures.

Sect. II. *Of Leases and Rent.*

Few subjects in agriculture are more important, or attended with more difficulty, than the proper mode of fixing the duration of leases, and the amount of rent; for, with these points, the mutual security and prosperity of both landlord and tenant are very closely connected.

Leases.—With regard to leases, it may be observed, that when they are of short duration, and clogged with injudicious restrictive clauses, they are equally injurious to the interests of the proprietor and occupier of land, and may be justly considered as the most serious obstacles in the way of all improvement.

The certain duration of a lease, on the one hand, becomes a powerful stimulus to the tenant to follow out that system which he conceives the most effectual for rendering the soil productive, and, on the other, restrains him from whatever mode of cropping he knows will render it unfruitful; and thus it appears to be of incalculable importance to individual benefit, as well as public prosperity. He who can look on his farm as his permanent residence, will naturally be led to every species of improvement. He will plant, and drain, and manure, in the hope that all such expenses will be ultimately and certainly repaid. Permanence and security of tenure being the great incitements to all improvement, Lord Kames proposes, that at the expiration of twenty-one years, if the tenant offer an adequate additional rent, with the view of continuing in the farm, the landlord may be at liberty to take it into his own occupation on paying to the tenant ten years purchase of this additional rent. This principle of renting land seems highly favourable to every kind of improvement; but it may be questioned, whether a less considerable purchase would not answer the intentions of such a lease. Could leases be formed on such a principle, the interests of the proprietor and tenant, instead of clashing, as they generally do in most instances, would be mutually increased. From the security afforded by such a tenure, the one is stimulated to additional exertion, while the other has the satisfaction of perceiving his land rapidly advancing to the highest state of cultivation. The genius of the farmer, in this way, is not restrained by restrictive modes of cultivation; and the income of the landlord is not diminished by the deterioration of his property.

Rent.—Various modes have been adopted for regulating and fixing the amount of rent. In most cases, the rent is valued and paid in money; but many intelligent agriculturists are of opinion, that great advantage would result to both tenant and landlord by the substitution of corn-rents; that is, by rents regulated according to the average price of corn in the market where the tenant disposes of his produce. By this means the landlord is secured of a just income, and the tenant pays rent in proportion to the actual produce of his farm. Should the landlord be satisfied with the character, circumstances, and enterprise of the tenant, the quality of the land requires only to be estimated by good judges; and should it appear to be of the first-rate value, the average produce is divided into three parts, one of which is given to the landlord, one to the tenant, and a third to the farm. This practice is very prevalent on the continent, but may be considered as only applicable to land of the very best and most productive quality. Supposing the land so let to produce twelve bolls of oats at an average per acre, the landlord would in this case receive from four to five pounds in a dear year, but in a cheap year only from forty to fifty shillings. As the value of corn-rents often varies considerably from year to year, it becomes necessary to calculate the average price during several years, otherwise corn-rent is suited only to leases of long duration; for experience proves, that when grain is scarce, and prices are very high, the landlord, in such seasons, has a much greater advantage than the tenant can have when the corn is abundant and the prices are low.

As land of inferior quality, however, requires not only a more expensive mode of cultivation, but also much skill, capital, and industry, to improve and keep it in a productive state, the fourth part of the produce may, in this case, be considered as the fair value of rent; and from the examinations of the most intelligent agriculturists lately before the Committee of the House of Commons, even the fifth part of the actual produce of land of the worst quality was deemed a sufficient return to the landlord. In all leases, therefore, founded on such principles, the quality of the soil must determine the proportion to which the landlord is entitled in name of rent, whether it be a third, a fourth, or a fifth part of the actual produce.

But the amount of rent may be determined according to the average price of labour, which fluctuates less annually than the money price of corn. If the average price of labour could be ascertained, many are of opinion that this would be the most invariable measure for rent, because it varies less from year to year than the price of corn, and is generally accommodated to the average price of all the necessaries of life. Were it as practicable to ascertain the money price of labour in every parish, as it now is to determine the fiar prices of grain in every county, it would be extremely easy to fix the price of rent according to this rule; and this might even be practised by every tenant calculating the average price of the wages he pays annually to all such labourers and servants as he employs on his farm. But a more eligible mode of fixing the rent would be, not by any one of these rules, but in a just proportion of all the three; that is, partly in money, partly according to the price of labour, and partly according to the price of corn. Thus, if the rent of a farm be valued at L.300 *per annum*, supposing the average price of a day's labour through the year to be two shillings per day, and the boll of corn or oats to be twenty shillings; the tenant, in this case, would pay the price of a thousand days labour, the price of an hundred bolls of oats, and one hundred pounds in money, per annum, during the currency of his lease.

Perhaps the best mode that can be devised for fixing the rent, is to make it payable according to a certain number of bolls of such grain as the land commonly produces, expressly declaring that the maximum shall not exceed a certain sum. Thus, if the farm be valued at L.500, the rent is converted into 250 bolls, or 125 quarters of wheat; and if the average or fiars price of the year be 30s. per boll, the

Leases, &c. rent will be L.375; but if the average price be L.2, then the rent will be precisely the stipulated sum of L.500; and if the fiars should rise to L.3 per boll, the rent can never exceed the stipulated amount of L.500.

Agrigentum. Agrippa.

AGRIGENTUM, an ancient city of Sicily, the place of which is now partly occupied by the modern Girgenti. It was called Acragas by the Greeks, from its situation on a steep rock. See Girgenti.

AGRIMONIA, a genus of plants belonging to the Dodecandria class, of which the species *eupatoria*, or agrimony, was formerly used in medicine.

Hemp Agrimony, *eupatorium cannabinum*, belongs to the Syngenesia class.

Water Hemp Agrimony, *bidens*, is also arranged under the Syngenesia class of plants.

AGRIPPA, Henry Cornelius, a singular character for the variety of his pursuits and the versatility of his talents, was descended from a noble family, and was born at Cologne in 1486. In early life he entered into the Austrian service, in the capacity of secretary to the emperor; and having distinguished himself in Italy by his military prowess, he received suitable marks of honour from that monarch; but his ambition was not satisfied with military fame, and his literary acquirements enabled him to distinguish himself on a different scene. At this time the fascinating pursuit of the discovery of the philosopher's stone was the chief occupation of many eminent scholars. Agrippa joined in the pursuit, acquired great reputation as an alchemist, and in this character, according to the spirit and fashion of the times, travelled in different countries of Europe. During his stay in England, he was occupied in the study of theology, and when he returned to the continent he read lectures on that subject in his native city. The same course was repeated at Pavia and Turin in Italy; but the unsettled life of the lecturer afforded a very scanty provision for a wife and son, which now composed his family.

The first permanent situation which Agrippa seems to have enjoyed, was the office of advocate and orator of the city of Metz; but he was not destined to remain long in this honourable station. The freedom of his remarks on matters of religion, excited the jealousy and persecution of the monks and clergy, who at last compelled him to resign his situation, and seek shelter elsewhere. His stay at Cologne, to which place he had retired, was short; and assuming a new character, for several years afterwards he practised as a physician in Switzerland and France. While at Lyons, he was fortunate in being appointed physician to Louisa of Savoy, mother of Francis I. with a handsome pension; but his refusal of complying with her request, to predict, according to his astrological knowledge, the success of the arms of her son, was again fatal to his prosperity. Dismissed from her service, and thrown unprovided on the world, he next settled at Antwerp, where the splendour of his talents excited universal admiration, and procured for him various invitations and promises of protection from the most distinguished characters. Accepting of the patronage of Margaret of Austria, governess of the Low Countries, he was appointed historiographer to her brother, the Emperor Charles V., and soon after published the history of his government. But the severe treatment and ill fortune of Agrippa had not yet taught him the lessons of prudence; for, with an unsparing hand, he attacked the errors and prejudices of the times, in a work entitled "*The Vanity of the Sciences*," and roused a powerful host of new enemies. He again lost his patroness and his pension; was thrown into prison for debt; and was no sooner relieved from confinement than he involved himself in a new controversy and persecution, by the publication of a treatise on "*Occult Philosophy*," in which he attempts an exposition of the harmony of the elementary, the intellectual, and celestial worlds. The freedom and violence with which he assailed the errors of the clergy, and the bigotry of the times, which were invariably his favourite themes, provoked the resentment of his enemies, and compelled him to wander for shelter from place to place. While at Lyons, the publication of some satirical compositions against Louisa of Savoy, his former patroness, again deprived him of his liberty. The interposition of friends procured his release; and after a short retirement at Grenoble, death relieved him from all his troubles, in 1535, and in the 49th year of his age.

The life of Agrippa exhibits a remarkable display of varied, of extraordinary talents; and in better times, when alchemy and astrology have vanished before the brighter light of true philosophy, such wonderful powers would have raised their possessor to the very first rank of eminence. But with this brilliant assemblage of intellectual endowments, Agrippa possessed few of the conciliatory virtues. He was rash, imprudent, capricious, and restless; and to a fickle and unsteady temper, not less than to the bigotry and persecuting spirit of the age, are to be ascribed the trouble and disquiet which embittered his days, and pursued him closely through the changing scenes of his eventful career.

Agrippa, Herod, the grandson of Herod the Great, was born about seven years before the birth of Christ; was elevated to the throne of Judea by the emperor Caligula; and in early life was chiefly distinguished by his excessive profusion and extravagance, even among the luxurious Romans. While Herod Agrippa held the sovereignty of Judea, his uncle, Herod Antipas, who had married his sister Herodias, was tetrarch of Galilee, and was ambitious of the name and dignity of king, had repaired to Rome, at the instigation of his wife, to present his request at the imperial throne. Letters from his nephew, Herod Agrippa, charging him with treachery and correspondence with the enemies of Rome, were delivered at the same time to Caligula, who deposed him from his government, sent him into exile, and enlarged the dominions of his nephew, by uniting Galilee with Judea.

Herod Agrippa, to conciliate the favour of the Jews, and to secure his popularity among that people, seems to have encouraged and promoted the persecution of the Christians. James, the brother of John the Evangelist, was put to death, and the apostle Peter suffered imprisonment by the orders of Herod. The close of his life is well known. Arrayed in all the pomp and splendour of eastern magnificence, he received the ambassadors who had come from Tyre and Sidon to sue for peace; and while the words which he uttered were re-echoed by the impious exclamation, "it is the voice of a god, and not of a man," he was seized with a violent distemper, his body was devoured by worms, and, after suffering the most severe agony, he died about the year 44. *Acts*, chap. xii.

Agrippa was the only son of Herod Agrippa, and succeeded his uncle as king of Chalcis, a Roman province. Agrippa is the person mentioned in the Acts of the Apostles, before whom, and his sister Berenice, and Festus governor of Judea, the apostle Paul, who had been imprisoned two years before, and had appealed to the emperor at Rome, defended himself. *Acts*, chap. xxvi.

AGRIPPINA, the daughter of Germanicus, was born at Cologne, in Germany, was greatly admired for her beauty, and so celebrated for her literary acquirements, that Tacitus, the historian, acknowledges himself indebted to her writings; but she was not less remarkable for profligacy, cruelty, and pride. She was three times married; and having persuaded her last husband, the emperor Claudius, who was her own uncle, to adopt her son Nero, she planned the destruction of the former, and at last executed the horrid purpose by poison, to pave the way for the latter to the imperial throne. Nero, her son, who had not failed to profit by the examples of cruelty and profligacy exhibited by his mother, became jealous and impatient of her influence and authority in the government; and having failed in an attempt to have her removed by drowning, issued orders that she should be privately murdered. When the executioner was about to perpetrate the bloody deed, she entreated him to stab her in the belly, which had brought forth so cruel a monster.

AGROSTEMMA, Wild Lychnis, Campion, or Corn-Cockle, a genus of plants belonging to the Decandria class, one species of which is not uncommon in corn fields.

AGROSTIS, Bent-Grass, a genus of plants belonging to the class Triandria. Creeping bent-grass, belonging to this genus, is the celebrated Irish fiorin.

AGUE, the common name of intermittent fevers, or such as have periodical returns of the paroxysm or fit. See Medicine.

AGUILLANEUF, a ceremony which was observed by the ancient Franks, at the commencement of the new year, the origin of which is traced to the Druids, who, with great solemnity, cut off the misletoe of the oak, and, after consecration, distributed it among the people on the first day of the year. The word is composed of *a*, to, *gui*, misletoe, and *l'an neuf*, the new year; practices which seem to have had the same origin, are still prevalent in some parts of France.

AGUR, who is mentioned in the book of Proverbs as the son of Jakeh, is by many supposed to be the same with Solomon, who describes himself under that name; but others think, that Agur and Lemuel, whose name also occurs in the same book, were wise men who flourished in the time of Solomon. Prov. chap. xxx. and xxxi.

AHAB, a king of Israel, who surpassed all his predecessors in acts of impiety and oppression. At the instigation of his wife Jezebel, he established idolatry in his kingdom, for which he was reproved by the prophet Elijah, and a famine of three years in his dominions was predicted. In his time, and at the request of Elijah, the people of Israel, and the prophets of Baal, were assembled to offer sacrifice; and it was proposed by the prophet to ascertain whether Jehovah or Baal were the true god, by calling upon them separately to consume the offering by fire from heaven. At the prayer of Elijah his burnt-offering was consumed, but the idol Baal was invoked in vain. His priests were instantly put to death, and the famine was removed from the land. The oppression and wickedness of Ahab, in which he was aided by the artifice of his wife, were remarkably exemplified, in compassing, by means of false testimony, the death of Naboth, an inhabitant of Jezreel, and seizing his vineyard, to extend the gardens of his palace. For this wickedness, he was threatened by the prophet with the judgments of heaven upon his house. Ahab, during great part of his reign of 22 years, was engaged in war with the Assyrians. He was wounded with an arrow as he conducted his troops to attack Ramoth-Gilead, and died in the evening of the same day, 897 years before Christ. His chariot, which was stained with his blood, was washed at the fish-pool of Samaria, and the prediction of the prophet, that the dogs should lick his blood, was thus fulfilled. 1 Kings, chap. xvii.

AHAZ, who succeeded his father Jotham, was king of Judah, during an unfortunate reign of 16 years. His territories were invaded by the kings of Syria and of Israel, and were constantly exposed to the incursions of surrounding nations. To procure the assistance of the king of Assyria against this overwhelming force, Ahaz exhausted his treasury, and despoiled the temple of its ornaments. He was attached to idolatry; suppressed the worship and sacrifices in the temple, and erected altars to idols in every part of his dominions. 2 Kings, chap. xvi.; 2 Chron. chap. xxviii.

AHAZIAH, king of Israel, was the son of Ahab, and succeeded his father. Like him, he was attached to idolatry; and having dispatched messengers to consult the god of Ekron about his recovery from a dangerous illness, they were met by the prophet Elijah, who assured them that the king should die. Ahaziah, displeased at the intimation, ordered the prophet to be apprehended; but two of his officers, with 50 men each, in attempting to execute his command, were destroyed by fire from heaven. Elijah agreed to accompany another party which was sent to bring him before the king, and again warned him of his end, as the punishment of forsaking the true God; and the prediction of the prophet was verified by the death of Ahaziah, after a short reign of two years, and 895 years before Christ. 2 Kings, chap. i.

AHITOPHEL, the friend and counsellor, and afterwards the violent enemy of David king of Israel. When Absalom rebelled against his father, Ahitophel joined him, and became one of the most active conspirators. The plans which he suggested, and the vigorous measures which he proposed to carry them into execution, seriously threatened the power and authority of David; but other counsels prevailed, and the sagacious Ahitophel perceiving the certain ruin of the rebels, from the inefficiency of their conduct, or disappointed that his advice was rejected, went to his house, and destroyed himself. 2 Sam. chap. xv. and xvi.

AHLEDEN, a district in the principality of Lunenburg Zell, in Germany, is about five miles in length, and abounds with timber, great quantities of which are floated to Bremen for exportation.

AHMEDABAD, or Amedabad, the capital of the province of Guzerat, in Hindostan, received its name from Sultan Ahmed, who was king of the province. The city, which is situated in a fine plain, watered by the river Sabermatty, is more than four miles long, including the suburbs, has 12 gates, and is well fortified. The principal buildings are, the castle, the palace, the caravanseray, and the English factory; and none of the least remarkable are two hospitals, established by the Hindoos, one of which is appropriated for the reception of sick birds, and the other for sick beasts. It was taken by the British in 1780, and restored to the Mahrattas in 1783. E. Long. 72° 37′. N. Lat. 22° 58′.

A-HULL, the situation of a ship when her sails are furled on account of the violence of the storm; her helm is lashed to the lee side, and she lies nearly with her side to the wind and sea.

AHUYS, a small sea-port town of Gothland in Sweden, about 18 miles from Christianstadt.

AJACCIO, or Ajazzo, a sea-port town of Corsica, situated on the north side of a gulf of the same name, which lies on the south-west coast, is the capital of the island, contains more than 6000 inhabitants, and will be long remembered as the birthplace of Bonaparte. Excellent wines are produced in the vicinity; the coral fishery is a considerable source of trade, and the gulf affords good anchorage to ships of large burden.

AJAN, a country of Africa, having Abyssinia on the north, and the Indian ocean on the east, and extending to Cape Guardafui. This country is celebrated for its breed of horses, and in the northern parts it abounds with all kinds of provisions. On some parts of the coast the inhabitants are white, and have long hair.

AJAX, the son of Telamon, was one of the bravest warriors among the Greeks in the Trojan war, and is celebrated by Ovid as the competitor with Ulysses for the armour of Achilles. Disappointed of this prize, he became deprived of his reason, according to one account, but according to another, he destroyed himself.

Ajax, the son of Oileus, prince of the Locrians, was one of the principal Grecian leaders in the siege of Troy, and furnished 40 vessels for that expedition. He was transfixed with a thunderbolt, and his fleet was dispersed by a storm, through the influence of the goddess Minerva, in whose temple he had committed an outrage on Cassandra the daughter of Priam.

AJAZZO. See Ajaccio.

AICHSTADT, a city of Franconia, in Germany, the capital of a bishopric, in whose cathedral is deposited a vessel of gold of extraordinary richness and magnificence. It is called the Sun of the Holy Sacrament, and is said to be decorated with 350 diamonds, 1400 pearls, 250 rubies, and other precious stones. Aichstadt is 37 miles south of Nuremberg.

AILESBURY, or Aylesbury, a small borough town in Buckinghamshire, which consists of about 400 houses, sends two members to parliament, and is 44 miles north-west from London.

AILSA, a remarkable insulated rock, at the entrance of the frith of Clyde, and between the coasts of Cantyre and Ayrshire, in Scotland, is of a conical form, about two miles in circumference at the base, and rises to the height of nearly 1000 feet above the level of the sea; is accessible only by a small bay on one side; and the remains of a fort, vaguely reported to have been erected by Philip II. about the time of the invasion by the Spanish Armada, are still visible on a precipitous cliff. Ailsa is the summer resort of innumerable flocks of sea-fowl, particularly the solan goose and the puffin, which are annually taken in vast numbers on account of their feathers. The banks in the neighbourhood of Ailsa abound with fish.

AINSWORTH, Robert, a learned grammarian, and author of a well known Latin dictionary, was born in 1660 at Woodyale in Lancashire; was educated at Bolton, in the same county, where he taught a school for some time; removed to Bethnal Green, and afterwards to Hackney, where he superintended a seminary for the education of youth; and having acquired a moderate competency, retired from his laborious profession, and devoted his time to antiquarian researches, especially to the collection of old coins. His Dictionary of the Latin language, which was begun in 1714, and occupied 22 years of his life, was first published in quarto, in the year 1736; and enriched with the improvements and additions of succeeding lexicographers, it is now regarded as the completest dictionary of that language. A ridiculous story is in circulation, and is formally announced on pretended good authority, that his wife, disappointed at being deprived of his company, while he was occupied in the composition of the dictionary, committed the whole manuscript, which was brought down to the letter S, to the flames; and that his indefatigable industry and patience soon repaired the loss. Mr Ainsworth died at London, and was buried at Poplar. A monumental inscription in Latin, composed by himself, appears on his tombstone.

AIR, the thin, transparent, compressed fluid which surrounds the globe of the earth. For an account of its properties, see Chemistry, Meteorology, and Pneumatics.

Air, in *Music*, in its strictest acceptation, signifies a composition for a single voice, and applied to words; although the meaning is sometimes extended to any melody the passages of which are so constructed as to be within the limits of vocal expression; or which, when it is sung or played, forms a connected chain of sounds, which is called a *tune*.

Air and Airshire, a town and county in Scotland. See Ayr and Ayrshire.

Aira, Hair-Grass, a genus of plants belonging to the class Triandria.

Air-Balloon. See Aerostation.

Air-Bladder, a peculiar organ in fishes, by the compression and dilatation of which they have the power of rising and sinking in the water.

Air-Gun. See Pneumatics.

Air-Pump. See Pneumatics.

AISNE, one of the northern departments of France, derives its name from the river, which is navigable through the whole department; contains a population of more than 430,000; produces corn, fruits, and cattle, and supplies Paris with wood from its extensive forests. The manufacture of glass is carried on in the forest of St Gobin. Laon is the capital of this department.

AITON, William, an eminent botanist and gardener, was born in 1731, at a small village near Hamilton, in Scotland. In 1754 he went to England, and was employed as an assistant in the physic-garden at Chelsea, under the celebrated Philip Miller; and five years afterwards he was appointed by the Princess-Dowager of Wales to the superintendance of the botanical garden at Kew; a situation which he retained during life. In 1789, he published a catalogue of the plants cultivated in this garden, under the title of *Hortus Kewensis*, in 3 vols. 8vo, containing 13 plates, and an enumeration of between 5000 and 6000 species; with notices of the first introduction of particular exotics into England. Mr Aiton died in 1793.

AJUGA, Bugle, a genus of plants belonging to the Didynamia class, of which three species are natives of Britain.

AIUS Locutus, or Loquens, which signifies *speaking voice*, a deity to whom the Romans erected an altar. A voice was heard by night near the temple of Vesta, informing the Romans of the approach of the Gauls: The warning was neglected; but when the event confirmed its truth, Camillus acknowledged the voice to be that of a new deity, and recommended the altar to be erected.

AIX, an ancient city of France, and capital of the department of the Mouths of the Rhone, formerly Provence, is said to have been the first Roman station in that country, where Caius Sextus Calvinus, the consul, established a colony more than 100 years before the Christian era; and from this consul, and the warm mineral springs of the place, the city derived the name of *Aquæ Sextiæ*. Few remains of antiquity are now visible; the ancient baths were only discovered about the beginning of the eighteenth century. The modern city is distinguished by elegant public buildings, spacious streets and squares, and a fine walk, shaded with trees, and cooled with fountains. In the church of one of the convents in the city, it is said that there is a silver statue of the Virgin Mary nearly the size of life. Aix has some trade in oil. The population exceeds 23,000; it is five leagues distant from Marseilles, and 163 from Paris.

AIX-LA-CHAPELLE, a fine city of Germany, in the circle of Westphalia and duchy of Juliers, is situated in a valley, and surrounded with mountains and woods. Aix-la-chapelle lays claim to considerable antiquity; was a place of note in the time of the Romans, who selected it as one of their stations, and, from its celebrated mineral waters, gave it the name of *urbs aquensis*, city of waters, and *aquægranii*, or waters of Granius; and became the residence of the emperor Charlemagne, who rebuilt and enlarged it after the destructive ravages of the Huns under their leader Attila, in the year 451. A chapel, erected by Charlemagne, and dedicated to the Virgin, was the origin of its present distinctive appellation. The coronation of the king of the Romans was formerly performed in this place, where, it is said, the sword of Charlemagne, the book of the gospels, jewels, &c. employed in that ceremony, are still preserved. The more ancient city, about two miles in circumference, is included in another of later date, and more than double its extent, and both are surrounded with walls and flanked with towers. The city is traversed by many rivulets; some of which drive machinery; and it is adorned and refreshed by twenty public fountains, one of which, distinguished by its elegance, is surmounted by a statue of Charlemagne, of gilt brass. Some of the public edifices are remarkable for their magnificence; among which the cathedral and stadthouse hold the first place. The latter fabric consists of three stories. The uppermost is occupied by one apartment of 160 feet in length and 60 in breadth. The treaties of peace between France and Spain, in 1668, and between France, England, and the allies, in 1748, were arranged and concluded in this city. The population exceeds 23,000.

But the chief celebrity of Aix-la-Chapelle is derived from its mineral waters, which attract strangers from very distant regions. The waters contain sulphuretted hydrogen gas, which, as it escapes, deposits the sulphur, and the latter is sometimes collected and sold, carbonate of lime and soda, and common salt. The temperature varies from 112° to 143° Fahr. The waters are used internally or by bathing; and for the latter purpose numerous and commodious baths are constructed.

AKENSIDE, MARK, a celebrated poet, was born at Newcastle-upon-Tyne, in 1721. His father, a butcher by trade, destined him for the ministry among the presbyterian dissenters, and sent him, at the age of eighteen, to the University of Edinburgh, where he might complete an education that had been rapidly advanced at the free school and a private academy in his native place. The clerical profession not suiting the taste of the young man, those studies, which are commonly directed towards it, were abandoned at the close of his first college session, when he devoted himself with eagerness to the cultivation of general literature, and finally resolved on the medical profession. Having formed this determination, he repaid a certain contribution, allotted by the English dissenters for the instruction of their poorer theological scholars, on which partly he had hitherto been maintained, but to which, considering his altered views, he honourably thought he had now no claim.

The medical school of Edinburgh at this time had not risen to that eminence which it afterwards acquired, though possessed of some important advantages productive of its future greatness. Its rising consequence still acknowledged the superior dignity of the Dutch professors. Our poet, accordingly, after a residence in that University of three years, diligently and variously occupied, repaired to Leyden, where, in 1744, he took his degree in medicine; and at this place he became intimate with Mr Dyson, then a student of civil law, to whose friendship and liberality he was subsequently indebted for very substantial favours. On his return to England, in the same year, he published the poem by which his name is consecrated in the history of our literature. How long this brilliant production, "The Pleasures of Imagination," had employed his genius, does not exactly appear; but there can be little doubt that its basis at least was adjusted previously to his residence in Edinburgh, where he had been noted for poetical talents. The success of this performance was flattering at its first appearance. In the words of Pope, whose advice, according to Dr Johnson's information, had been taken by Dodsley the publisher, as to the reasonableness of the price demanded for it, which was L.120, the author "was no every-day writer." There existed few poems in the language, indeed, a comparison with which Akenside might have scrupled to encounter; and in certain qualities essential to excellence, it is still questionable if he has ever been surpassed. But to this commendation, it is neither invidious nor unnecessary to add, that he himself did not every day write so well. Some smaller pieces of a later growth were not equal to his early promise; and the many alterations which he projected on this work at various times, and by which, had they been fully effected, it must have been subjected to a very different character, are more remarkable for a solicitude to justify public opinion, than calculated to command it by irresistible flashes of genius. The faculty of invention, in which, perhaps, he was originally defective, could not emerge from the process of correction. The mind of Akenside was so disciplined to thought, and furnished with all the ordinary helps which ensure accuracy, that it might have safely trusted itself in the loftiest flights of fancy, totally regardless of those restraints which are too often imposed by the caprices of criticism; and perhaps it needed such indulgence to divest itself of a stiff, though dignified deportment, which seems to have been induced by warm admiration of antiquity, and excessive attachment to classical learning.

The circumstances of the private life of Akenside, it may be suspected, contributed not a little to check the efforts of his muse in attempting higher degrees of poetic excellence. He was mortified in an unequal struggle with Dr Stonehouse, who had successfully preceded him in medical practice at Northampton; and having left that place, first for Hampstead, and then for the capital, where he had still more formidable difficulties to encounter, he was saved the necessity of exertion, which so frequently proves the source of eminence, by the offer of L.300 a-year from his friend Dyson, till his profession afforded him an adequate income. A bounty so unusual was perhaps more creditable to the giver than salutary to the receiver, as it probably proved obstructive of his muse's compassionating inspirations.

The fame of Akenside as a poet, which had been his precursor in London, the well-founded confidence of his friends in the superiority of his talents, and the extent of his acquirements, added to a prudential use of all the common modes of attracting notice, procured him distinction, though some peculiarities of manner, and an accommodating temper of mind, were wanting to obtain popularity as a physician among numerous candidates. At last, however, he made some progress in professional employment and reputation; he became physician to St Thomas' Hospital; and among the honours at which he successively arrived, was his appointment of physician to the queen. This took place a little before his death, which was occasioned by a putrid fever, in June 1770, and in the 49th year of his age.

Akenside's poetical works, viz. "The Pleasures of Imagination," as last modelled by himself, and two books of odes on various occasions, were published by Mr Dyson, who survived him, in 1772.

His Treatises on subjects belonging to medical science, which he seems to have conscientiously prosecuted, are mostly all inserted in the Philosophical Transactions. Our opinion of Akenside's genius as a poet has been partly stated. "The Pleasures of Imagination," the only production by which his name can be preserved from oblivion, must be judged by a peculiar standard. It is a didactic poem, on a subject which, besides being of difficult discussion, had descended to him previously entangled in opinions rendered venerable by their antiquity, and become still more enticing by the refining artifices of modern philosophy.

The chief excellencies of Akenside are, ardent devotion to what is truly good, strength of conception, richness of imagery, and a noble command of elegancies in language and sentiment; his chief faults are more to be regretted than condemned; want of originality, narrowness of invention, and a kind of perplexed exuberance of ideas, which, unless the reader is perfectly familiar with the exercise it occasions, is apt utterly to distract attention from the main object that is thought entitled to such extraordinary accompaniments. "In the general fabrication of his lines," says Dr Johnson, "he is perhaps superior to any other writer of blank verse; his flow is smooth, and his pauses are musical; but the concatenation of his verses is commonly too long continued, and the full close does not recur with sufficient frequency. The sense is carried on through a long intertexture of complicated clauses, and as nothing is distinguished nothing is remembered."

AL, an Arabic particle, signifying *the*, which is prefixed to words, as Al Kali, Alkoran, the Kali, the Koran.

ALABASTER, a common name which has been long applied to some varieties of gypsum, or plaster of Paris, which are employed for the purposes of statuary and ornamental productions, as vases and small figures for the interior of apartments. It is also applied to some kinds of marble or carbonate of lime. See MINERALOGY.

ALAMAGAN, one of the Ladrone islands in the Indian ocean, is about 12 miles in circumference; the land is in some places so elevated, that it is seen at the distance of 12 or 14 leagues; and a volcanic mountain, close to the sea, rises to the height of 1200 or 1500 feet.

ALAND, with its dependent islands, about 80 in number, is situated between the gulfs of Bothnia and Finland, in the Baltic. These islands lie between N. Lat. 59° 47′ and 60° 30′, and between E. Long. 19° 17′ and 22° 7′. Aland, the principal island, is about 20 miles long, and 16 broad. The inhabitants of this island, the number of which, in 1772, exceeded 19,000, are employed in agriculture, in fishing, or the ordinary mechanic arts. Wheat, rye, oats, and barley, are sufficiently productive in some parts of the island; the climate is in general favourable, and the sea around the island is seldom frozen. The inhabitants of Aland resemble the peasants of Sweden in their dress, manners, and customs. The mountains are chiefly composed of red granite; the quadrupeds and birds are such as are common to northern regions, and fish are abundant.

ALANS, a warlike and barbarous people, supposed to be of Tartar origin, who seem to have first occupied the mountainous region near the source of the river Jaick. Migrating southwards, they settled on the Danube, in the year 406; traversed Gaul, and afterwards entered Spain, and seized many of its finest provinces. Discomfited and dispersed by the Goths and Franks, their name was finally blended and lost in that of their conquerors. The Alans resembled the Tartars by travelling in waggons; in regarding their flocks as their riches; in adorning the trappings of their horses with the scalps of their enemies; in their attachment to warlike exercises; and in considering the warrior peculiarly fortunate who died in the field.

ALARIC I. a celebrated Gothic leader, and king of the Visigoths, was first distinguished when he passed the Danube, in the year 376, with an army of 200,000 men. According to the policy of the Roman emperors, who engaged one tribe of barbarians to protect the provinces against the inroads of others, Alaric appeared in a conspicuous and efficient character in the Gothic war which ended in 382; but thinking himself overlooked, and his services neglected, he collected his army, and laid waste the finest provinces of Greece. Even the city of Athens was only spared in consequence of the earnest intreaties and humble submission of the inhabitants. Advancing into Peloponnesus, his career of cruelty and blood received a slight check; but having amused and deceived the rival emperors by his cunning and treachery, he invaded Italy in the year 400, and ravaged it without opposition. Alaric suffered another check from a successful attack of the Romans, who overthrew his army with great slaughter. In his second invasion of Italy he appeared before the walls of Rome, and having received large sums of money, raised the siege; but his army being reinforced, he again invested the capital, took it by assault, deposed the emperor, and gave up the city to the plunder of his soldiers, which was continued for six days with the most ferocious cruelty, and with no regard to rank, age, or sex. This happened in the year 410. Alaric died the following year, while his troops were preparing to embark for Sicily; and it is not a little singular, that the place of his burial was the channel of a river, the waters of which were for a time turned from their course, to allow the body to be deposited in the grave.

ALARIC II. a king of the Visigoths, succeeded his father Euric in the year 484, and possessed the sovereignty of the whole intermediate country between the rivers Rhone and Garonne. The name of Alaric has been transmitted to posterity in consequence of his attempt to adapt the laws of the emperor Theodosius to the genius and character of his own people. These institutes are known by the title of the Code of Alaric; the Arian controversy keenly prevailed in the time of his reign, and he not only espoused the heresy, but supported its tenets by the power of the sword. Clovis, the king of the Franks, advanced with an army against him, and routed the Goths. The two kings agreed to meet in single combat, and Alaric fell in the encounter, which took place in the year 507.

ALAUDA, the lark, a genus of birds belonging to the order of Passeres. See ORNITHOLOGY.

ALAY, which signifies triumph, is a singular ceremony observed by the Turks at the commencement of war. The alay begins with a procession, in which artizans, seated in splendid cars, exhibit to the spectators the implements of their trades, and the mode of operation. The standard of the prophet, which is conveyed from the seraglio, and is to be presented to the army, next follows, and is beheld with the most fanatical enthusiasm. The Emirs only are permitted to touch it, and the look of an infidel is regarded as the most dreadful profanation. On one occasion, described by Baron Tott, the Emir who preceded the consecrated banner, exclaimed with a loud voice: "Let no infidel profane with his presence the standard of the prophet, and let every mussulman who discovers an unbeliever make it known, under pain of reprobation." The Christians, ignorant or unsuspicious of danger, had crowded to witness the ceremony, and were in a moment involved in one undistinguished massacre.

ALBA, or Alba Fucensis, from its vicinity to the Fucine lake, now called Albi, is an ancient town of Italy, and is noted in Roman history as the state prison, where captive princes, after being exhibited in a public triumph, were confined. It is situated in a mountainous region, and the remains of a fortification, as well as the ruins of an amphitheatre, a temple, and some other public buildings, are still visible.

ALBA is also the ancient name of several Roman towns, as Alba Helviorum, now Viviers in Languedoc, in France; Alba Julia, now Weissenburg, in Transylvania; and Alba Longa, in Italy, which was established by Ascanius, the son of Æneas, at the foot of the Albanian mount, was the royal residence till the building of Rome, and was destroyed by Tullus Hostilius, and the inhabitants were removed to Rome.

ALBAN, ST. reputed the first Christian martyr in Britain, was born at Verulam, and flourished about the end of the third century; visited Rome in company with Amphibalus, a monk of Caerleon, and served as a soldier for seven years in the army of Dioclesian; after his return to his native country was converted to Christianity, through the influence and instructions of the monk who had been his friend and companion; and suffered martyrdom about the year 303, during the persecutions which raged under the reign of that emperor. Numerous miracles, it is said, accompanied his execution. St Alban was held in such veneration, that, more than four centuries after his death, Offa, king of the Mercians, erected a magnificent monastery to his memory. About the middle of the 13th century, when the church was repaired, some leaden chests, containing relics, were discovered, one of which was supposed to be the depository of the body of the martyr. The town of St Albans derives its name from this saint.

ALBANI, or ALBANO, FRANCIS, an eminent painter, was born at Bologna in Italy, in 1578. He discovered an attachment to painting at the early age of 12, and studied, first under Denys Calvert, and afterwards in the school of the Caracci, along with the celebrated Guido Rheni, with whom he contracted a very intimate friendship; but a rivalship for fame in the same profession soon dissolved the connection. Albani afterwards resided many years at Rome; and on the death of his first wife returned to his native city, where he married a beautiful and handsome young lady, who, with her children, served as the models of his Venuses and cupids, and, it is supposed, contributed to give that sameness of form and attitude which is observed in his figures. The reputation of Albani procured him general respect while he lived; he received the visits of the most distinguished persons in his own profession; enjoyed the correspondence of several princes; and was invited to England by Charles I. in a letter signed with his own hand. His paintings are admired for elegance of design and harmony of colouring. His most celebrated picture is that of the four elements, in the palace of Turin; and his smaller pictures grace the cabinets of most collectors. Albani died in 1660, at the advanced age of 82. The following is a translation of some epigrammatic verses which were intended for his monumental inscription, and are still preserved:

"The mortal remains of the illustrious Albani, who gave life to shade, lie interred in this tomb; the earth never produced so wonderful an artist, or a hand like his, which gave colours to the soul, and a soul to colours. Prometheus animated clay, and gave life by means of the sun; but Albani animated merely by the assistance of shade."

ALBANIA, an ancient kingdom of Asia, which lies chiefly between the Euxine and Caspian seas, and is bounded on the north by mount Caucasus. It is now known by the names of Schirwan and East Georgia. Albania was formerly an independent kingdom, and it is doubtful whether it was ever under complete subjection to the Roman power. Many parts of the country are extremely fertile. The men of Albania are celebrated by ancient historians for their comeliness, stature, and strength; and the beauty of the women is highly extolled by modern travellers.

ALBANIA, the ancient Epirus, is an extensive province of the Turkish empire, which lies between the 39th and 43d degrees of north latitude, stretching about 250 miles along the coast of the Mediterranean and the Gulf of Venice. The greatest breadth inland is not more than 100 miles, and towards the south it does not exceed 30 miles. The mountainous chain of the ancient Pindus separates this country from Macedonia and Thessaly.

The Albanians first rose to distinction on the decline of the Greek empire; by their valour they resisted the Bulgarians, who had become masters of the contiguous provinces of Greece; and, under the command of the celebrated leader George Castriot, better known by the name of Scanderbeg, they successfully opposed Mahomet II. the conqueror of Constantinople, who employed the most vigorous efforts in their subjugation; but, after all his exertions, he was compelled formally to acknowledge their independence. The death of their leader, and the renewed attacks of the Turks, forced them, in 1478, to submit to a state of nominal subjection, which seems never to have been general or cordial.

Revolts were not uncommon in many parts of the province; the inhabitants of the mountainous regions never gave up their independence; and now, by the energy and vigorous enterprize of Ali Pasha, its present governor, Albania almost holds the rank of a separate kingdom. Since the year 1811, when he gained possession of some of the most fertile parts of the country, and added to his government a population of nearly 300,000 souls, his power is almost absolute. Such, indeed, is his political influence, that, it is said, Bonaparte solicited his favour, and, with his usual liberality, offered to raise him to the dignity of king of Albania; but the Pasha had the sagacity to perceive the ambitious designs of the French ruler, and considered it a wiser policy to attach himself to Britain. This bold chief keeps up an army of 10,000 men; his revenue, of which a small part only is supposed to be remitted to Constantinople, is considerable, and his annual income from private property is estimated at L.200,000 Sterling. An immense building near Joannina, the capital of the country, which may be considered as a kind of fortified palace, is the usual residence of Ali. His haram, in which are immured 300 females, is a distinct edifice, and fitted up in a most magnificent style.

The inhabitants of this country are estimated at 1,200,000; they are of a gay, lively, and active character; averse to regular industry, strongly attached to arms and plunder, and think it no disgrace to join the numerous bands of robbers who infest the mountainous districts. They are not very rigid followers of the prophet; and indeed the true believers regard them as infidels. The women are held in a greater degree of contempt than is usual even among the most barbarous nations. The Turkish cavalry, known by the name of *Arnauts*, are raised in Albania.

Joannina, the capital of Albania, finely situated on the banks of a lake, is very irregularly built; but as it is interspersed with trees and gardens, and surrounded with lofty mountains, it presents a picturesque appearance. The inhabitants are estimated at 35,000. Among the Greek residents science and literature are not neglected; and the commerce of Albania is in the hands of the same people, who conduct it through Arta, a town in the southern district of the country, and situated on a gulf of the same name. Among the exports are enumerated, timber for building, and fire-wood to Malta; grain to the same place; to Italy, and the Ionian isles, wool and some coarse cloth, cotton and cotton yarn, oil and tobacco. Guns, gunpowder, hardware, coffee and sugar, are included in the list of imports. A very active commercial scene is annually exhibited in October, at a fair held in the vicinity of the capital. See Hobhouse's *Travels in Albania*, and Holland's *Travels in the Ionian Isles and Albania*.

ALBANO, a town of Italy in the Campagna di Roma, and on the banks of a lake from which the name is derived. Ancient monuments, some of which are reputed, on doubtful authority, to be the tombs of Ascanius, the son of Æneas, and of the celebrated Horatii and Curiatii, are seen at the entrance of the town; and the ruins of Domitian's palace in the vicinity are also visible. The lake, which is seven miles in circumference, and embosomed in an amphitheatre of lofty mountains, the Barberini palace, with its fine gardens, and the salubrious climate, render Albano an attractive spot, and an agreeable summer retirement to the Roman nobility. It is 15 miles south-east from Rome.

ALBANS, St. a borough and market-town of Hertfordshire in England, near the spot where the ancient Roman city Verulam stood, the place of which is marked only by the remains of some mud walls and the occasional discovery of Roman coins and fragments of pottery. The monastery was erected in the end of the 8th century, by Offa, king of the Mercians, to the memory of St Alban. The church still remains, and contains the tombs of the founder, and of Humphrey, Duke of Gloucester. The body of the latter, in a leaden coffin, and pretty entire, was discovered in a vault about the beginning of the 18th century. A monument to the memory of the great reformer of philosophy, Lord Bacon, is erected in St Michael's church. St Albans is a great wheat market. The population exceeds 4000, and it is 21 miles distant from London.

ALBANY, the capital of a county of the same name in the state of New York in North America, situated near the head of Hudson's river, and in the midst of a fertile country, traversed with numerous navigable lakes and rivers, and affording every kind of facility to commercial intercourse. The manufacture of starch, mustard, hair-powder, snuff, and tobacco, is conducted on a large scale at works in the neighbourhood, which are chiefly moved by water. The inhabitants, collected from all parts of the world, were estimated, in 1797, at more than 6000. Albany is 160 miles distant from New York, and 340 south from Quebec.

ALBERONI, Julius, a distinguished statesman, was the son of a gardener at Placentia, where he was born in 1664, continued for some time in the same occupation, and rose to the rank of first minister of state in Spain. For some good offices which he had rendered to the Duke of Vendome's secretary, who had been robbed near the place where Alberoni resided, he was taken into the service of that famous general, accompanied him into Spain, where his powerful talents and bold ambition found ample scope; and having projected and accomplished the marriage of Philip V. and the Princess of Parma, through the interest of that princess he was advanced to the dignity of cardinal and archbishop of Valencia, and finally promoted to the head of affairs in the kingdom. Having effected certain internal arrangements which gave vigour and stability to the government, and having improved and strengthened the Spanish navy, Alberoni directed his ambitious views to the execution of bolder and more daring enterprises. The restoration of the pretender to the throne of England, the annihilation of the power of the Germans in Italy, and of the Duke of Orleans as regent in France, were among his favourite schemes; and to insure their successful accomplishment, he formed a strong alliance with Peter the Great of Russia, Charles XII. of Sweden, and the Ottoman Porte. France and England coalesced against this powerful combination; war was declared in 1719, and the preliminary to the negotiations for peace in the following year was the banishment of Alberoni. He retired from Spain loaded with wealth, spent the last years of his life in establishing a seminary in his native city for the education of the poor, and died in 1752, at the advanced age of 88.

ALBERT THE GREAT, in Latin ALBERTUS BOLSTADIUS, and sirnamed Grotus, or Magnus, a celebrated alchemist, was born at Lawingen in Swabia, about the end of the 12th, or beginning of the 13th century; was educated at Pavia and Paris, and became doctor of medicine; joined the order of Dominican friars, acquired great popularity as a teacher of theology and preacher of the crusades, and was promoted to the bishopric of Ratisbon, the dignity and emoluments of which he resigned, and returned to his cell at Cologne, where he first taught philosophy and divinity, and where he died in 1280.

The superior knowledge of Albert, which travelled far beyond the times in which he lived, drew down upon him the charge of being a magician and a conjurer. His "Book on Minerals," marks his proficiency in natural history; his "*Lilium floris de spinis avulsum*," "Lily of the flower plucked from the prickles," and "*Speculum alchemiæ de compositione lapidis*," "Mirror of alchemy concerning the composition of the stone," shew how deeply he was engaged in the pursuits of alchemy; and the collection of his works, chiefly philosophical and theological, printed in 1651, in 21 folio volumes, affords ample proof of the amazing extent of his industry.

ALBI, a town of Italy. See ALBA.

ALBI, a town of the department of Tarn in France, situated on an elevated bank of the river, is remarkable for the fine choir of the cathedral, a rich silver shrine of exquisite workmanship, in which are deposited the relics of St Clair, the first bishop, and a magnificent chapel dedicated to the same saint. Albi is celebrated for its fine shady walks, and for the richness and beauty of the surrounding scenery. The population is nearly 7000. The distance north-east from Toulouse is 35 miles, and 250 south from Paris.

ALBINO, a name which seems to have been first employed by the Portuguese to designate a variety of the negro race, in which a remarkable deviation in the colour and appearance of the skin, the hair, and the eyes, is observed. The peculiarities of this variety consist in the whiteness of the skin and hair, the redness of the eye, and great sensibility to light. The Albinos, or white Moors, as they have been called, are not confined to the natives of Africa. They have occasionally appeared both among Indians and Europeans; and in some parts of Africa and America, it is said, they are so numerous, that they are considered as a distinct race. Saussure, in his Travels on the Alps, particularly describes two Albinos, brothers, who were natives of the valley of Chamouni.

The researches of anatomists have discovered the immediate cause of the singular appearances in the Albino. The dead white colour of the skin is ascribed to the absence of the *rete mucosum*, or cellular membrane, to which the peculiar colour of the skin and hair is owing. In the negro this membrane is black, and therefore the complexion is the same. The pink or rose colour of the eye in the Albino, is traced to a similar defect, in the want of the black membrane, *pigmentum nigrum* of anatomists, on which the dark colour of the eye depends. A similar redness of the eye, which no doubt arises from the same cause, is observed in white varieties of some quadrupeds, as mice and rabbits. Albinos are generally observed also to have a relaxed and debilitated constitution, and to be deficient in strength and vigour; so that the appearances which they exhibit, and deviations from the ordinary structure of the species, are justly regarded as constituting a peculiar morbid condition of the body.

ALBINUS, BERNARD SIEGFRED, a celebrated anatomist, was born at Frankfort on the Oder, in the year 1697. His father was then professor of medicine in the university of Frankfort; but five years afterwards, being appointed to the professorship of anatomy and surgery at Leyden, he removed to that place, where the son had the best opportunities of improving himself in general literature, as well as in anatomy and surgery, to which he had now particularly devoted his studies, aided and encouraged by the celebrated anatomist Ruysch, and the no less famous lithotomist Rau, who then flourished at Leyden. After a year spent in Paris, Albinus was recalled, and at the recommendation of Boerhaave was appointed lecturer on anatomy and surgery, and on the death of his father, in 1721, professor of anatomy in the university of Leyden.

Albinus soon distinguished himself as an able and useful teacher, and continued to prosecute his favourite studies with great zeal and industry; but his labours were not confined to oral instruction. In 1734 he published *Historia Musculorum Hominis*, the History of the Human Muscles, one of the most splendid and accurate anatomical works which has yet appeared. In 1745, he was appointed professor of medicine in the same university, and was succeeded by his brother in the anatomical chair. With the same unabated zeal, and the same unwearied assiduity, he continued to discharge the duties of his office till the time of his death, which happened in September 1770. Beside the work already mentioned, Albinus was the author of many other valuable productions, connected with the illustration of anatomy and physiology.

ALBION, the ancient name of Britain. The origin of the name is not distinctly ascertained.

ALBION, NEW, a country on the north-west coast of America, which received the name from Sir Francis Drake, who discovered and took possession of it in 1578. This country, which is also called California, was visited by Captain Cook, La Perouse, and more lately by Captain Vancouver, who fixes the boundaries of New Albion between the 30th and 45th degree of N. latitude.

ALBIS, the ancient name of the Elbe, a river in Germany, was long the boundary of the Roman territory in this quarter of the world. Six years before the Christian era, a Roman general having crossed the river with a few troops, was deemed worthy of the honours of a triumph for that exploit.

ALBOURG, a town of Denmark. See AALBOURG.

ALBUCA, Bastard Star of Bethlehem, a genus of plants belonging to the Hexandria class.

ALBUGO, or LEUCOMA, a disease of the eye, or a white opaque spot growing upon the cornea.

ALBUM, a white table or register, in which the names of magistrates and public transactions were recorded. Of these registers there were various kinds, which were distinguished by different names among the Romans.

ALBUMEN, a substance which forms a constituent part, both of animal and vegetable matters, and exists in great abundance in the white of eggs.

ALBUQUERQUE, a town of Estremadura in Spain, is situated on an eminence, and has a considerable trade in wool and woollen manufactures. It is nine miles distant from the frontiers of Portugal, and 20 miles N. from Badajos.

ALBURNUM, a soft white substance, which lies between the inner bark andt he wood of trees, and, acquiring solidity, is converted into the wood itself.

ALCA, or AUK, a genus of birds belonging to the order of Anseres. See ORNITHOLOGY.

ALCÆUS, a celebrated Greek lyric poet, was born at Mitylene, in the island of Lesbos, and flourished about 600 years before the Christian era. He was cotemporary with the poetess Sappho. A very few fragments of his works now remain. His name and reputation have been transmitted to posterity in the works of others, and chiefly by the verses of Horace.

ALCAICS, the name of several kinds of verse, derived from Alcæus, the supposed inventor. One kind, composed of five feet, consists of a spondee, or iambus, an iambus, a long syllable, and two dactyls: another kind consists of two dactyls, and two trochees. These are called dactylic alcaics. The simple alcaic verse consists of an epitrite, two choriambuses, and a bacchius.

The alcaic ode consists of several strophes of four verses each; the first two verses were dactylic alcaics of the first kind; the third verse includes four iambic feet, with a long syllable; and the fourth is a dactylic alcaic of the second kind.

ALCAID, ALCADE, or ALCALDE, an officer of justice or magistrate among the Moors, Spaniards, and Portuguese. The duties of the alcaid in Spain correspond nearly with those of a justice of the peace in Britain; and, among the Moors, the same magistrate is invested with supreme authority, both in civil and criminal matters.

ALCALA DE HENARES, the ancient Complutium, is a beautiful city in New Castile, in Spain; is situated on the river Henares, and is celebrated for its university, which was founded in the 13th century, and restored and more richly endowed by Cardinal Ximenes in the 15th century. The library of the university formerly possessed many valuable manuscripts, which were collected at great expence; and from these manuscripts, and under the superintendance of the most learned men of the time, the celebrated Polyglot Bible, called from the place the Complutensian Polyglot, was printed by Cardinal Ximenes, in 1499. About the middle of the 18th century, many of these manuscripts, it is to be regretted, were disposed of by an ignorant librarian, as waste paper, to make room for new books. Alcala is twelve miles E. from Madrid, to which place the waters of a very pure spring are conveyed for the use of the royal family.

ALCANTARA, a town of Estremadura, in Spain, is situated on the banks of the Tagus, and is celebrated for its fine bridge, which was built in the time of the emperor Trajan. This bridge consists of six arches, is 670 feet in length, 28 in breadth, and rises 200 feet above the surface of the river. The accommodation of the bridge induced the Moors to select that spot for the city, from which the name Al Cantara, or *the Bridge*, is derived. It is 45 leagues from Madrid.

An ancient military order in Spain, denominated the Knights of Alcantara, took their name from this place. They were formerly called Knights of Calatrava, and seem to have been associated for the purpose of expelling the Moors.

ALCARES, a town of La Mancha in Spain, which is celebrated for an ancient aqueduct, and a breed of horses, which are remarkable for their fleetness and strength. It is 138 miles south-east from Madrid.

ALCARRAZAS, a kind of pottery ware, which is manufactured at Anduxar, in Andalusia, in Spain, and are employed for cooling liquids. These vessels are very porous, and as the liquid exudes through their substance, it evaporates rapidly from their external surface, and thus cools down the contained liquid far below the temperature of the atmosphere. Vessels of this kind are in common use in Spain, and are very generally employed in the warmer regions of the globe.

ALCEA, the Holly-hock, a genus of plants belonging to the class Monadelphia.

ALCEDO, the King-fisher, a genus of birds belonging to the order of Picæ. See ORNITHOLOGY.

ALCHEMILLA, Ladies Mantle, a genus of plants belonging to the class Tetrandria, and of which two species are natives of Britain.

ALCHEMY, or the CHEMISTRY, an art, or science, as some call it, which began to be studied about the third or fourth century, and continued to flourish for many ages. The captivating objects which alchemy held out to its disciples and followers were the philosopher's stone, by which the baser metals might be converted into gold, the universal medicine which should cure all diseases, and the universal solvent. Alchemy excited the notice of the Roman government in the time of the emperor Dioclesian, and the books which treated of the subject were ordered to be burnt. In England, it is curious to observe, the practice of alchemy was at one time, about the middle of the 15th century, permitted by licence, while, at other times, it was suppressed by severe edicts. See CHEMISTRY.

ALCIBIADES, a celebrated Athenian general, was not more distinguished by his talents in the field than by his eloquence in the Forum, by the versatility of his private character, than by the instability of his patriotism; now addicted to study and temperance, and now indulging in luxury and dissipation; now fighting the battles of the republic, and now leading the armies of its enemies against his country. His influence among the Athenians excited the jealousy of some of his fellow citizens; he was accused of sacrilege, and recalled from an expedition against Syracuse, to answer to the charge; but he declined the summons, and retired to Thebes; the sentence of condemnation was pronounced against him, and his property was confiscated. He joined the Lacedemonians, and led them to victory against his countrymen. The Lacedæmonians, in their turn, became jealous of his power; and, fearing his return to Athens, threatened his life. To escape the danger he fled, and, through the intercession of two Athenian generals, was restored to the favour of his countrymen, and again admitted to the command of their armies. He soon obliged the Lacedæmonians to sue for peace, and returning in triumph to Athens, was welcomed as a deliverer, recovered his possessions, and was loaded with honours. But such is the fickleness of popular applause, or the watchful jealousy which attended his steps, that the occurrence of a slight disaster again undermined his influence, and deprived him of his command. He retired into exile, and, with a small body of men, made incursions into Thrace; but dreading the vengeance of the Lacedæmonians, he deemed it prudent for his safety to take refuge with Pharnabazus, whose favour he soon obtained, and who bestowed upon him a possession in Phrygia. Endeavouring to secure the friendship and alliance of the Persian monarch on the side of the Athenians, he was basely attacked by a party of assassins, dispatched by Pharnabazus at the instigation of the Lacedæmonians. The assassins set fire to his house in the night, and slew him with arrows as he attempted to escape from the flames.

ALCINOUS, king of Phæacia, now the island of Corfu, is celebrated by Homer for his kindness and hospitality to Ulysses, who was shipwrecked on his coast, and is alluded to by poets on account of the magnificence of his gardens.

ALCMAER, the capital of North Holland, is situated on the banks of a drained marsh, between the North and Zuyder seas; is reckoned one of the handsomest and cleanest cities in the United Provinces; and remarkable for the regularity of the streets, the neatness of the houses, and the magnificence of the public buildings. The drained marsh land around the city is now converted into highly cultivated gardens, orchards, and rich meadows, which last afford abundance of the best butter and cheese in Holland. Alcmaer resisted the force of the Spanish arms during a siege of three months, in 1573. It was taken in 1799 by the British. Alcmaer is celebrated for the culture of flowers. The account of a remarkable sale of tulips, which took place in 1637, is still preserved in the records of the city, in which it is stated, that 120 roots with their offsets brought more than L.8000 Sterling. A single root, the Admiral of Enckhuysen, was sold for more than L.460 Sterling. Alcmaer is 24 miles distant N. W. from Amsterdam.

ALCOBACA, a town of Estremadura in Portugal, situated on the small river Alcoa. and chiefly remarkable for a rich monastery, which is the burial-place of the Portuguese royal family, and the manufacture of cambrics and woollens.

ALCOHOL, or ALKOHOL, rectified spirit of wine. See CHEMISTRY.

ALCORAN, or ALKORAN, the Scripture or Bible of the Mahometans. See KORAN.

ALCUIN, or ALCUINUS FLACCUS, an eminent English writer, who flourished about the end of the eighth century; was abbot of Canterbury; and being sent by the king of Mercia on an embassy to the emperor Charlemagne, he was invited to enter into the service of that monarch, and became his preceptor in the learning of the times. The rapid progress of letters during the splendid reign of Charlemagne, and the establishment and endowment of the universities of Paris, Tours, Soissons, and others, are ascribed to the influence and prudent exertions of Alcuin. Retiring in 801 from the active scenes of life to his abbey of St Martin's at Tours, he spent the remainder of his days in superintending a seminary of education which he had founded, and in acts of piety and devotion, and he died in 804. The works of Alcuin, published in a folio volume at Paris, in 1617, consist of tracts upon the Scriptures, morality, and history, of letters, and poems.

ALDERMAN, is a title to which various degrees of rank and authority have been attached in the progress of English history. Among the Saxons, it denoted a degree of nobility corresponding with earl or count, and afterwards was applied to a person who performed the duty of a judge. Alderman, in the present day, is a subordinate magistrate to the mayor of a city; and the number of these magistrates is regulated by the extent and population of the place. In London there are 26 aldermen, to each of whom a ward of the city is committed. The office is continued for life; and on the death or resignation of an alderman, a wardmote or meeting of the ward is held for the election of a successor to supply the vacancy.

ALDERNEY, an island on the coast of France, subject to Britain, is separated from Cape la Hogue, in Normandy, by a narrow strait, called the *Race of Alderney*, which is a dangerous passage in stormy weather; is eight miles in circumference; the soil is fertile and well cultivated, and it is remarkable for a fine breed of cows. The inhabitants, estimated at 1000, occupy a small town in the centre of the island. The Victory, of 110 guns, a British man-of-war, perished, in 1744, with her whole crew of 1100 persons, on the rocks in the neighbourhood of Alderney. N. Lat. 49°. 45′. W. Long. 2°. 7′.

ALDRED, archbishop of York, who flourished in the 11th century, rose from a humble station to that high ecclesiastical dignity; was in great favour with Edward the Confessor, and performed the ceremony of coronation to his successor, Harold, and to William the Conqueror. A remarkable instance of William's servility, and of Aldred's haughtiness, is recorded. One of the king's governors having offended the archbishop, he repaired to London with a train of ecclesiastics, rushed into the presence of the monarch, and threatened him with all the vengeance of the church. The king, terrified, threw himself at the feet of Aldred; and when the nobility expressed their indignation at the insolence of the prelate, he calmly replied, " Good men, let him lie there; he is not at Aldred's, but at St Peter's feet: he must feel St Peter's power, since he dared to injure his vicegerent." Aldred died in 1066.

ALDRICH, Henry, an English divine, who was born at Westminster in 1647; received his classical education under the celebrated Dr Busby; studied at Oxford; and was promoted, in 1689, by King William, to the deanery of Christ Church. In the controversial discussions concerning popery, in which he had engaged in the preceding reign, Bishop Burnet eulogises him as having treated the subject with a "solidity of judgment, clearness of argument, depth of learning, and vivacity of writing, far beyond any that had before that time appeared in our language." Dr Aldrich is better known on account of his attachment to music and the lighter species of poetry. Various services for the church, and a number of anthems, are acknowledged to be of his composition; two of his Latin poems are preserved in the *Musæ Anglicanæ;* he is the author of the popular catch, "Hark, the bonny Christ-Church bells;" and the following epigrammatic verses, entitled, "*Causæ bibendi,*"—"Reasons for drinking," are ascribed to him.

Si bene quid memini, causæ sunt quinque bibendi;
Hospitis adventus, præsens sitis atque futura,
Aut vini bonitas, aut quælibet altera causa.

If on my theme I rightly think,
There are five reasons why men drink—
Good wine, a friend, because I'm dry,
Or lest I should be by and bye,
Or any other reason why.

Dr Aldrich died in 1710, and in the 63d year of his age.

ALDROVANDI, Ulysses, a celebrated Italian naturalist, was born at Bologna in 1525, and became afterwards professor of philosophy and logic, and lecturer on botany in that university. But his name is transmitted to posterity as the laborious compiler of an extensive work on natural history. The expences which he incurred in the execution of this huge work reduced him to such poverty that he was compelled to seek an asylum in an hospital in Bologna, where he died in 1605, and in the 79th year of his age. The compilation which Aldrovandi projected, consists of thirteen folio volumes, which include all the departments of natural history; but the first six volumes only are to be considered as his work; the last seven volumes were drawn up on the same plan, and published after his death.

ALE, a fermented liquor obtained from an infusion of malt and hops, originally prepared, it is said, in Egypt, and used as a substitute for wine in those countries which are unfavourable to the production of the grape. See Brewing.

ALECTO, according to the heathen mythology, one of the three Furies, who is described as the daughter of Acheron and Night, or of Pluto and Proserpine.

ALEMBERT, John le Rond D', an eminent philosopher, was born at Paris in 1717. He was exposed by his mother near the church of Jean le Rond, from which he derives his name, and seemed so weak when discovered that scarcely any hope of life remained. The humanity of the commissary to whom such matters are intrusted, instead of consigning the infant to the ordinary receptacle destined for those whom parental affection has abandoned, committed him to the care of the wife of a glazier, and thus probably preserved his existence. The father of D'Alembert, touched with the kindness of strangers to his neglected offspring, came forward and provided for the education and independence of his child. D'Alembert was indebted to the Jansenists of the college of the Four Nations for the elements of learning, and his progress afforded early promise of rising genius. A commentary on the epistle of Paul to the Romans, which he composed in the first year of his philosophical studies, gave his masters the pleasing hope that their young pupil would become a second Pascal, and the means of reviving the ancient splendour of their establishment; but their expectations were soon disappointed, for nothing could allure him from mathematical and physical science, in which he then engaged.

When he retired from college, and found himself alone in the world, he returned to the house of his nurse, with the resolution of devoting himself to his favourite studies, and in this humble abode he spent 40 years of his life. To increase his scanty income, which did not exceed 1200 livres a-year, he was induced, by the advice of his friends, to turn his attention to some professional employment; and with this view he studied law, which he relinquished for medicine, and finally abandoned both, that he might prosecute mathematics without interruption. In the year 1741, and at the early age of 24, he was admitted a member of the Academy of Sciences. Two years afterwards appeared his Treatise on Dynamics, in which a new principle of mechanics is developed. The discovery of this new principle was followed by that of a new calculus, the first application of which was made in his discourse on the general theory of the winds, to which the prize medal of the academy of Berlin was adjudged in 1746. This treatise was dedicated to the great Frederick, in the following flattering verses, which obtained for their author a letter from the king, and the honour of being ranked among his literary friends:

Haec ego de ventis, dum ventorum ocyor alis,
Palantes agit Austriacos Fredericus, et orbi,
Insignis lauro, ramum prætendit olivae.

Swifter than winds, while of the winds I write,
The foes of conquering Frederick speed their flight;
While laurel o'er the hero's temple bends,
To the tir'd world the olive branch he sends.

In 1747 D'Alembert applied his new calculus to the problem of vibrating chords; in 1749 he furnished a method of applying his principle to the motion of any body of a given figure; in 1752 he published a *Treatise on the Resistance of Fluids*, and *Elements of the Theory and Practice of Music;* and about the same time his *Researches concerning the Integral Calculus*, appeared in the Memoirs of the Academy of Berlin. The reputation of D'Alembert was long confined to a small circle of friends, or only extended to those who were engaged in kindred studies; and indeed it does not appear that at any time he was very solicitous to obtrude himself on public notice. Of men of rank and station to whom he was known at this period, Messrs D'Argenson only are mentioned; but they were capable of appreciating his talents, and through their influence with the French king he was rewarded with a pension.

The publication of the Encyclopaedia, in conjunction with Diderot, exhibited a fine display of the varied powers and fertile genius of D'Alembert. The preliminary discourse on the origin, progress, and connections of the different branches of human knowledge, which he furnished to that celebrated work, has been universally acknowledged as a striking specimen of just arrangement and sound criticism, and a perfect model of accurate thinking and elegant writing; although a verbose hypercritic of the present day, after having studied and admired it for more than thirty years, has at last made the notable discovery, that the views of D'Alembert, as well as those of his great praecursor, the illustrious reformer of philosophy, Lord Bacon, are altogether erroneous; and, seemingly for the purpose of shewing with what dexterity he can wield the weapons of controversy in refuting their reasonings, at once pronounces them unsound and illogical. No great ingenuity or strength of arm is necessary to reduce the noblest building to a heap of ruins, but a powerful mind and vigorous exertion are required in the contrivance, arrangement, and disposition of the several parts of a grand edifice, to give solidity, uniformity, and elegance to the entire structure.

The unrestrained freedom of thought, and the little indulgence shewn to established opinions which appeared in the Encyclopædia, not only in religious and political affairs, but in the manners and more ordinary concerns of mankind, involved D'Alembert and his associates in much controversial discussion; and, perhaps with no great fairness or candour, the resentment and opposition which they had rashly provoked, are ascribed to a determined conspiracy, formed and supported by envy and detraction. While D'Alembert was suffering under literary persecution, the King of Prussia invited him to his court, with an offer of the place of President of the Academy; and, some time before, the Empress of Russia had solicited him to superintend the education of the Grand Duke; but he preferred the retirement and studious ease of private life to the dazzling honours and splendid distinctions of royal favour.

Beside the works already referred to, D'Alembert was the author of *Miscellanies*, philosophical and historical, &c.; *Researches* on several important points of the system of the world; *Elements of Philosophy;* and, in three years from the time when he was elected secretary to the French academy in 1772, he formed and executed the grand design of writing the lives of deceased members from 1700 to 1772, a work of great labour and industry, which included 70 *eloges* or biographical sketches.

Under the humble roof of his nurse, D'Alembert had spent the greater part of his life. A severe illness, in 1765, required him to remove to a more airy and healthy situation. He recovered his strength, and resumed his studies, which he continued to prosecute with ardour till his death in October 1783, and in the 66th year of his age. Candour, modesty, disinterestedness, beneficence, and simplicity of manners, are the amiable features in the character of D'Alembert; and his conversation, cheerful, lively, and full of anecdote, and the delicate sallies of his wit, not always unmixed with satire, rendered him an agreeable and interesting companion.

ALEMBIC, an old chemical vessel for distillation, now disused, and replaced by the commodious apparatus of the still and the retort.

ALENÇON, a small city of France, and capital of the department of Orne, is situated in a fertile plain on the banks of the river Sarte. The number of inhabitants exceeds 12,000; the chief manufactures are lace, linen, woollen stuffs, and leather; and it is 100 miles S. W. from Paris.

ALENTEJO, an extensive province of Portugal, which is bounded on the north by the Tagus, and on the west by the Atlantic ocean, is more than 100 miles in length, and nearly the same in breadth, and contains above 260,000 inhabitants. The soil is, in general, fertile, producing wheat, rye, barley, grapes, and olives, but the cultivation is very imperfect. This province has been often the seat of war, to which is ascribed its diminished population.

ALEPPO, or HALEB, the metropolis of modern Syria, and considered as the third city of the Ottoman empire, is situated in an extensive plain, which reaches from the Orontes to the Euphrates; is erected on eight hills, on the most elevated of which stands the castle; and is supposed by many to be the ancient Beræa. The ruins, still visible, sufficiently indicate its great antiquity. To the north-west of the castle, probably the site of the ancient city, marble pillars have been frequently discovered, at a considerable depth below the surface. Many of the streets of Aleppo are spacious and well paved, and in some of them a greater degree of cleanliness is preserved than in any other city of the Turkish empire. The houses are large and commodious, with terraced roofs; and the loftiness of the apartments, lighted from the top, with the gilded window-shutters, produces a striking effect at first entrance. The mosques are numerous, and some of them possess considerable magnificence. In an area before each, a fountain supplies the water which is required for ablutions before prayers. Aleppo is furnished with many large caravanserays, consisting of a spacious square, with a number of rooms on all sides of it, built on the ground-floor, which are occasionally employed as chambers, warehouses, or stables. The galleries on each side, on the second floor, are divided into many small apartments, where the natives and strangers transact the greater part of their mercantile affairs.

The market-places are long, narrow, covered streets, on each side of which are many small shops, barely sufficient to contain the tradesman and his goods, in consequence of which the purchaser must stand without. Each branch of business has its own market-place or *bazar*, which is locked up as well as the streets, about an hour and a half before sunset; and while the doors are cased with iron, the locks are made of wood. The suburbs contain the slaughter-houses, which are open to the fields; the

the tanners have a khan, in which they work in the vicinity of the river; a little below is a village, where ropes and catgut are manufactured; and coarse white glass is made on the opposite side of the river. The soil around Aleppo is rich and fertile; and the gardens, which are extensive, and well cultivated produce abundance of vegetables and delicious fruits. Aleppo is the emporium of Armenia and Diarbekir; sends caravans to Bagdad and Persia, and communicates with the Persian gulf and India by Bassorah, and with Europe by Alexandretta. Commerce is chiefly conducted by means of barter.

The air of Aleppo is dry and piercing, but, at the same time, salubrious; the summer heats are greatly moderated by the west winds. The population of Aleppo is, by some, computed at 285,000, while others state it so low as 100,000; but the estimate of Dr Russel, who resided there many years as physician to the British factory, makes the total amount 235,000, of whom 200,000 are Turks, 30,000 Christians, and the remainder Jews. With respect to religion, the people of Aleppo are more tolerant than the Turks of other countries; but they are said to be effeminate, and wholly averse to bodily exertions. The plague is supposed to appear in Aleppo once in ten years, and its ravages are sometimes terrible. The greater part of the time of the natives is spent in the prayers and ablutions prescribed by the Koran, in smoking tobacco, and in the immoderate use of the bath, the waters of which are often heated to about 100°. Aleppo lies 250 miles N. of Jerusalem. N. Lat. 35° 47′, E. Long. 37° 40′.

ALETRIS, a genus of plants belonging to the Hexandria class.

ALEUTIAN, or ALEUTSKY ISLANDS, are situated in the northern Pacific ocean, and form a chain of small islands, which extends from the promontory of Alaska, in North America, to the peninsula of Kamschatka, in the Russian territory. These islands have been divided into three groups; the first, called the *Fox islands*, lies nearest the American promontory; the central is called *Andrianofskoi*; and the third, properly called *Aleutian Islands*, is contiguous to the coast of Kamtschatka. They were little known till towards the middle of the 18th century. Peter the Great of Russia, a short time before his death, which happened in 1725, had projected a voyage of discovery in these remote regions, for the purpose of ascertaining the distance between the two continents of Asia and America; but the expedition did not take place till 1728, when Captain Behring was engaged in the enterprise; but it was not till he had made a third voyage in 1741 that the American coast was discovered; and on his return to Kamtschatka he was shipwrecked, and soon after died on the island which now bears his name. Numerous voyages were undertaken, either by private individuals or companies, for the purpose of hunting those animals which afford valuable furs, or, under the authority of government, for the purpose of farther discovery. The eastern part of this chain of islands was visited by Captain Cook, in 1778, during his last voyage. The whole were explored by Captain Billings, in 1796; and a still later expedition was appointed by the Russian government in 1803. The whole chain of the Aleutian islands is included within the 52° and 55° of N. Lat. and 169° and 183° of E. Long.

Behring's island, the most westward of the group, lies nearest to Kamtschatka; Copper island, which has been so denominated from masses of copper found on the beach, is situated ten leagues to the eastward; several small islands belong to this westerly group, which are succeeded by the central group, which is less known. The Fox islands, so called from the abundance of those animals found upon them, are the most important, and best known of the whole chain. Of this group, Umnak, Oonalashka, which is particularly described by Captain Cook, and Unimak, are the most considerable. The Aleutian islands exhibit a bare and mountainous aspect; their rocky coasts render navigation extremely dangerous, but some of them have commodious bays, and excellent anchoring places. The rocks seem to be of a basaltic nature; and in several of the islands volcanoes are still in a state of activity. The soil in the sheltered valleys produces abundance of grass; and in some of the islands it seemed fit for raising grain. The chief vegetable productions are of spontaneous growth, as bramble-berries, cran-berries, heath-berries, and some others; the only cultivated root is the potatoe, which has been lately introduced by the Russians, succeeds well, and is greatly relished by the natives. The dwarf birch, willow, and some other plants of shrubby growth, make the nearest approach to the character of trees; the wood employed in building is wafted from the American shores.

Among the land animals of the Aleutian islands, are enumerated bears, wolves, river otters, river beavers, and ermines; foxes, as black, grey, red, and brown, which abound in the Fox islands. The sea otter, whose fur is extremely valuable, seals, dolphins, and whales, are common in the neighbouring seas. Several kinds of salmon, cod, herrings, and holibut, of a very large size, are abundant.

The population of these islands is stated to have been at one time very considerable, but it is now greatly diminished, owing, it is said, partly to the oppression to which they are subject, and the change in their mode of life since they came under the Russian dominion, and partly to many of the hunters being sent to a distance, in chace of the large sea otter, and few of them returning from this dangerous occupation. The dress of the natives, which is nearly the same both in men and women, is chiefly composed of seal skins, and consists of a kind of frock, or shirt. Fish, sea animals, birds, roots, and berries, form the chief part of their food, and it is generally eaten in a raw state. Their habitations are merely holes dug in the earth, which are covered with a wooden roof, over which a quantity of grass and loose soil is thrown, giving their villages somewhat of the appearance of a church-yard. The entrance is by the roof; and through an opening in it, covered with a dry fish skin, the light is also admitted. The inhabitants, who are of low stature and of a swarthy complexion, are described as an honest, peaceable, and inoffensive people; but when their passions are roused, they become extremely furious, fearless of danger, and indifferent to death itself. The dreadful vengeance which they have more than once executed on the Russian adventurers, in massacring the whole crew of some of their ships when opportunity offered, may be regarded rather as a severe retribution for the oppression and cruelty which they suffered from rapacious traders, than as a mark of a barbarous disposition.

With the knife and hatchet alone, the latter a very rude instrument, the natives of these islands construct all their domestic utensils, and contrive to give them some degree of elegance and ornament. A needle is formed of the wing-bone of a bird; and with this all kinds of sewing, and a coarse sort of embroidery, are executed by the women. The Aleutian canoe is a frame of wood covered with leather made of seals-skins. It is usually constructed for a single person, sometimes for two, and very rarely for three, and is so light that it may be easily lifted up with one hand. The dart or javelin is employed in the destruction of prey, whether winged, land, or sea animals; and in the use of this weapon, which is discharged from a small board, the islanders display great dexterity.

Dancing is a favourite amusement. A small drum, and a rattle composed of a dried membranous bag, in which are introduced peas or small pebbles, are their only musical instruments. Their vacant hours in the long winter evenings are filled up with the manufacture of fine mats, small baskets, and pocket-books of straw, which are constructed with much neatness, and are not destitute of elegance. Toys, in the figure of men, fish, and such animals as are familiar to their observation, are made of the teeth of the sea cow, a substance whose hardness is greater than ivory, and which is brought into shape more by manual dexterity than by the perfection of the instruments employed. The houses have no fire-place; they are heated, as well as lighted, in the winter season, with lamps which are formed of a flat stone, with a concavity in the middle to receive the oil. A little dry grass serves the purpose of a wick.

The natives of the Aleutian islands, since their intercourse with Russia, are professedly attached to the Greek church; but, without intellectual culture, it is no wonder that their minds are still deeply obscured by the gloom of superstition. Marriage is marked by no nuptial ceremony; and the number of wives is only limited by choice, or the means of support. The sale or exchange of wives is said not to be uncommon. Many ceremonial rites were formerly observed in the burial of the dead; their best clothes and javelins, and a portion of oil and food were deposited with them in the grave; and, in the barbarous period of their history, the horrid sacrifice of slaves of both sexes was practised.

The fur-trade is the great object of Russian enterprize in these remote regions. It was originally in the hands of private adventurers, whose cruelty and rapacity at one time threatened the total extirpation both of the inhabitants and the animals on which it depended. The establishment of companies under the authority of government, and the introduction of regulations, have, in some degree, improved it; but the rapid decline of the population is a melancholy and certain proof of the oppression and poverty to which the unfortunate islanders are still subjected. The fur of the sea-otter is esteemed the most valuable; but the increasing destruction of these animals has greatly diminished their number, and made them rare in these islands. The furs of foxes of different colours, as black, red, brown, grey, or blue, are also in great estimation. The furs collected in the Aleutian islands are a source of great commercial wealth to the Russians; and the most lucrative branch of the trade extends to the Chinese empire.

ALEXANDER THE GREAT, the son of Philip of Macedon, and the most celebrated military character in ancient history, was born about 355 years before Christ. The father, the most able general and profoundest politician of the age, was indefatigable in his exertions to destroy the liberties of Greece, and boundless in his ambition to extend the Macedonian power. Dissensions, and mutual distrust, among the Grecian states, had opposed their co-operation in attempting the invasion of Persia; but when the whole were subject to the dominion of Philip, he was placed at the head of the combined forces of Greece, and immediately prepared to carry into effect the long projected plan; but he was prematurely murdered, and, in consequence of a misunderstanding which had existed between the father and son, on account of Olympias, the mother of the latter, having been divorced, Alexander was not free from the suspicion of being an accomplice in the horrid deed.

Alexander gave early indications of splendid talents and powerful military capacity; but the aversion of the Greeks to the usurped authority of Philip, the youth of his successor, then only in his twentieth year, and the determined opposition of the orator Demosthenes to his whole house, induced them to seize this opportunity of throwing off the yoke; and while Alexander was absent in reducing some barbarous countries to submission, the Thebans, who had been encouraged by the report of his death, rose in open rebellion. In returning to quell it, the rapidity of his march at once astonished and disconcerted the insurgents; they were forced to an engagement; Thebes, after a desperate resistance, was taken by storm; the buildings, with the exception of the house of Pindar the poet, were levelled with the ground, and 30,000 of the inhabitants were sold as slaves. This severe measure overawed the Grecian states, and repressed any future attempt at the recovery of their independence.

The tranquillity of Greece seemed to afford a fit opportunity for resuming the favourite scheme of the invasion of Persia. All Greece, the Lacedæmonians excepted, united in the enterprise; and at an assembly of the states, held at Corinth, Alexander was chosen the leader of their armies. With an army of 30,000 foot and 5000 horse, a force seemingly altogether unequal to so arduous an attempt, he crossed the Hellespont, where the generals of Darius, with 100,000 foot and 20,000 horse, were prepared to meet him. The position of the enemy on the banks of the Granicus obliged Alexander to cross that river before he could give them battle. He threw himself into the stream at the head of some troops of horse, and was in great danger before the whole of his little army had effected the passage of the river. The attack was so sudden and unexpected, that the Persians fled with the utmost precipitation and disorder; and the slaughter was so terrible, that they lost 20,000 foot, and more than 2000 horse. The city of Sardis, with its immense wealth, fell into his hands as the consequence of this victory.

The Macedonian hero opened his next campaign in the spring; and having overrun Paphlagonia and Cappadocia, he advanced by rapid marches into Cilicia. The attack of a fever, which was induced by bathing in the river Cydnus, threw his army into some confusion; but his recovery, at the end of three days, revived their confidence, and enabled him to advance to meet the Persian monarch, at the head of an army of 600,000 men. Darius, by some unaccountable infatuation, left the open country, and took up a position in the narrow defiles of Cilicia. The two armies having passed each other in the night, met at Issus, where a dreadful engagement took place. The crowded ranks of the Persians seemed only calculated to accelerate their destruction; and more than 100,000 men are recorded to have fallen in this bloody conflict.

In following up this decisive victory, Alexander determined to make himself master of all the cities on the coast; and though he had received the submission of the inhabitants of Tyre by their deputies, yet they declined to admit him within the walls; and it was not till after a seven months siege that he obtained possession of the city. He then directed his steps towards Egypt, at that time subject to Persia; and glad of an opportunity of being rescued from that yoke, welcomed him as its deliverer. On a visit to the temple of Jupiter-Ammon, Alexander was honoured and flattered with the title of *Son of Jupiter*. When Alexander returned to Tyre, he received a proposition from Darius, to surrender the whole country between the Euphrates and the Hellespont; but the ambition of the conqueror was not bounded by such limits; and the refusal was followed by another sanguinary conflict, which took place near Arbela; in which the Persians had an army of 600,000 foot and 40,000 horse, while the army of Alexander amounted only to 40,000 foot and about 8000 cavalry. The battle was dreadful, and the Persians were totally routed, with the loss of half their army. This victory decided the fate of Persia. Alexander entered Babylon, and the murder of Darius, which was soon after perpetrated by his rebellious subjects, left him entire master of the country.

Alexander now resolved to carry his victorious arms to more distant regions in the east; and had proceeded as far as the river Hyphasis, which is supposed to be the modern Beyah; but the murmurs of his soldiers had increased to insubordination, and he was compelled to abandon the attempt. Resigning all prospects of future conquest, he determined to explore the country which he had already traversed. Crocodiles were observed in the rivers which fall into the Indus, and as they were supposed to exist only in the Nile, or its tributary streams, he concluded that he had discovered the sources of that celebrated river. With this view, he prepared a fleet to proceed to Egypt. An adventurous voyage of nine months brought him to the ocean. He ordered the fleet to sail through the Persian gulf, and then to ascend the Tigris, for the purpose of meeting him and his army in Mesopotamia, while he conducted his forces by land to Babylon. He accomplished the arduous journey with the loss of a fourth part of his army. At Babylon, he began to meditate new schemes of future conquest; but here his career of glory terminated by his death, which happened 323 years before the Christian era, and in the 33d year of his age.

"Alexander," says Dr Gillies, "was of a low stature, and somewhat deformed; but the activity and elevation of his mind animated and ennobled his frame. By a life of continual labour, and by an early and habitual practice of the gymnastic exercises, he had hardened his body against the impressions of cold and heat, hunger and thirst, and prepared his robust constitution for bearing such exertions of strength and activity as have appeared incredible to the undisciplined softness of modern times. In generosity and prowess he rivalled the greatest heroes of antiquity; and in the race of glory, having finally outstripped all competitors, became ambitious to surpass himself. His superior skill in war gave uninterrupted success to his arms; and his natural humanity, enlightened by the philosophy of Greece, taught him to improve his conquests to the best interests of mankind. His actions were not always blameless; but his faults were few in number, and resulted from his situation rather than from his character."

Tomb of Alexander.—The body of this renowned monarch, after his death, was enshrined in a golden chase-work, fitted to the skin, and covered with a garment also of gold, over which was thrown a purple robe, and the whole was enclosed in his armour. The preparations for his funeral, which was conducted in a style of unexampled magnificence, occupied two years. The body, placed in a splendid car, was conveyed with great pomp from Babylon to Alexandria, and deposited in the tomb constructed for it by Ptolemy. The tomb was held in great veneration, and even worshipped by the Egyptians; three hundred years after Alexander's death, the Roman emperor Augustus beheld the body of the conqueror still entire; and even the Mahometans, long after the body had been removed, regarded the sarcophagus with pious respect. It was seized by the French, and put on board a ship to be transported as a rich trophy to France; but when Alexandria fell into the hands of the British in 1801, it was included in the surrender.

This precious relic of antiquity, which is now deposited in the British Museum, is composed of a single block of Egyptian breccia, ten feet long, about five feet broad, and nearly four feet high. It is sculptured all over with an innumerable variety of hieroglyphic figures, some of which, from the durable quality of the stone, are, after the lapse of more than 2000 years, in excellent preservation.

ALEXANDRETTA, called by the Turks Scanderoon, is the port of Aleppo, and situated in the gulph of Ajazzo, about 70 miles from the city. The harbour affords good anchorage; but the land-winds, to which it is exposed, sometimes make vessels drag their anchors for many miles, and render it impossible to enter it during some months of the year. A marshy plain on the land side surrounds Alexandretta, in consequence of which it is extremely unhealthy. A malignant fever prevails from May to September, by the ravages of which the whole crew of a ship has been cut off in a few months. That the natives breathe a very insalubrious air at all seasons, is manifest from their sickly, cadaverous appearance. Thus, hostile to health, Alexandretta derives all its importance from being the port of Aleppo.

ALEXANDRIA, called Scanderia by the Turks, is a city of Lower Egypt, lying on the Mediterranean. Although this city has now dwindled into insignificance, it was once the most flourishing and highly celebrated in the world, the populous capital of the Egyptian monarchs, and for ages the grand emporium of commerce and of riches. Alexander the Great was its founder, who gave it his own name, 333 years before Christ; and it is believed to be the only surviving monument of the extensive conquests of that far-famed hero. The immense importance of commerce, and the almost endless resources of a maritime power, were no doubt suggested to Alexander by the severe check which his triumphant career suffered before the city of Tyre, and probably led him to found Alexandria, after the conquest of Egypt; a city which flourished for ages, and engrossed the commerce of the eastern and western worlds, before a passage was discovered to the Indies by the Cape of Good Hope.

Alexander himself is said to have marked out the plan of this city; the celebrated Dinocrates, who rebuilt the temple of Diana at Ephesus, was the architect; and when the conqueror returned from his excursion into Upper Egypt, which lasted about a year, the building was far advanced. The streets were uncommonly splendid and spacious; one of them, 2000 feet broad, which extended in length from the gate of the sea to that of Canopus, was intersected at right angles by another of the same breadth, so that at their junction they formed a square of $1\frac{1}{7}$ mile in circumference. The greatest glory of this city was its harbour, a deep and secure bay in the Mediterranean, in which numerous fleets might ride in perfect security. The palace and gardens of the Ptolemies, monarchs to whom Alexandria was indebted for much of its glory, were situated near the promontory of Lectreos, and contained within their inclosures the Museum, an asylum for men of letters, groves and noble buildings, and a temple in which Alexander's remains were deposited. Alexandria became the royal residence, A.M. 3700, in the reign of Ptolemy Soter, who founded the famous Alexandrian library, containing at last 700,000 volumes. This city passed into the hands of the Romans on the death of Cleopatra; and under the Greeks and Romans, as well as the Ptolemies, it continued, for almost 1000 years, to maintain its reputation for wealth and literature; but under the dominion of the Saracens, it fell into a state of insignificance from which it never recovered. In the year 639, after a siege of fourteen months, Alexandria yielded to the arms of the Saracens, by whom its celebrated library was doomed to destruction, for the notable reason assigned by the caliph, " If the writings of the Greeks agree with the Koran, they are useless; if they disagree, they are pernicious, and must be destroyed." The precious contents of this splendid library supplied fuel to the 4000 baths of the city, among which they were distributed, for six weeks; and in that period, if the account be not exaggerated, were scarcely consumed.

In the present day, Alexandria exhibits a singular scene of magnificent ruin and desolation; the remains of obelisks, capitals, pilasters, and broken monuments of ancient art. The Pharos was long ago demolished, and a square castle, at once destitute of strength, ornament, and taste, was erected in its stead. The lake Mareotis no longer exists; its place is occupied by the Lybian sands. The modern city stands near the brink of the sea; the houses have flat, terraced roofs, and the streets are narrow and incommodious. The number of inhabitants does not exceed 5000. The language is Arabic; but most of the people are acquainted with the Italian. Alexandria was carried by assault on the 4th of July 1798, by the French under Bonaparte; in 1801, it was taken by the British, and was restored to the Turks at the termination of the war, in whose hands it still continues. N. Lat. 31° 11′, E. Long. 30° 16′.

Some other remarkable remains of ancient magnificence are still visible in Alexandria or its vicinity. The obelisks, which are known by the name of Cleopatra's needles, are composed of a single stone, 60 feet in height, and seven feet square at the base. They are covered with hieroglyphics. One of them is thrown down, and is nearly buried in the sand, but the other still remains on its pedestal. Some suppose that these columns decorated the entrance of the palace of the Ptolemies, the ruins of which still exist at no great distance.

Pompey's Pillar.—This celebrated column, which has attracted the attention of all travellers, and has been a fertile subject of conjecture among antiquarians, is situated about a quarter of a league from the southern gate of Alexandria. It is composed of red granite, or syenite of modern mineralogists, which is brought from Upper Egypt. The shaft, which is 90 feet in length, and nine feet in diameter, is supported by a block of marble 15 feet square, and the Corinthian capital is nine feet high; the height of the whole column is 114 feet. This column is not mentioned by ancient historians. Abulfeda, who describes Egypt, calls it the pillar of Severus, from which it is concluded that it is a monument erected to the memory of that emperor. The name of Pompey's pillar was not known till the 15th century, about the time of the revival of learning. Denon, who visited Egypt, in 1798, along with the French army, has entered into some ingenious speculations concerning this column; and considering that the pedestal and capital are of a different stone from the shaft, that their workmanship is heavy, and appears to be merely a rough draught, and that the foundations, composed of fragments, indicate a

Alfred.

modern construction, concludes, that this monument is not antique, and that it may have been erected in the time of the Greek emperors, or of the caliphs; and seems to hint, that the shaft at least belonged to some ancient edifice, and that it ought to be regarded merely as a fragment.

Catacombs.—The catacombs, or ancient burial-place of Alexandria, are at the distance of a mile south-west from the city. This necropolis, or city of the dead, is dug in a bed of solid rock; the excavation is from 30 to 40 feet wide, 200 feet long, and about 25 feet deep. From this proceed several openings about 10 or 12 feet in width, which form subterranean streets, one of which has been particularly examined, and it appears that niches 20 inches square, sunk 6 feet horizontally, narrowed at the bottom, and separated from each other by partitions in the rock, 7 or 8 inches thick, divide into checkers the two walls of this subterranean vault. The mummies, or embalmed bodies of the dead, seem to have been introduced with the feet foremost, into the cells intended for their reception.

ALFRED, King of England, from the splendour of his talents and the lustre of his reign, justly designated the Great, was the youngest son of Ethelwolf king of the West Saxons, was born at Wantage in Berkshire, in the year 849; and in 871, while in the 22d year of his age, succeeded his brother Ethelred on the throne. A large proportion of England was at this time occupied by the Danes; and, in the very commencement of his reign, Alfred took the field to resist their farther inroads. Various success for some time attended his arms; but at last the fortune of war changed, and he was reduced to such extremities, that he was abandoned by his subjects, and assuming the dress of a peasant, was obliged, in that disguise, to seek a temporary asylum in the cottage of a neat-herd; and historians have not thought it unworthy of record, that he submitted to reproof for negligence in the humblest menial offices. The total discomfiture of a considerable army of the Danes, and the capture of their magical standard, the possession of which was believed to render them invincible, in a bold attack of one of his adherents, revived the hopes of Alfred, and encouraged him, in concert with his nobility, with whom he secretly corresponded, to rally his scattered forces. But before active warfare commenced, Alfred, in the assumed character of a harper, entered the Danish camp, and carefully examined the strength and position of the enemy, returned to his friends, quickly assembled his forces, and, in an attack as sudden as it was unexpected, obtained a complete victory. The consequences of this victory were the recovery of London, a considerable extension of his dominions, and a period of several years tranquillity, which he wisely improved by strengthening and securing himself against future invasion. The repose of the kingdom was again disturbed in 893 by the arrival of a powerful fleet and a formidable army of Danes, who, aided by an insurrection of their countrymen formerly established in England, threatened the total overthrow of the power of Alfred. After a severe struggle, he was again successful, drove them from his dominions, and, by his wisdom and vigour, preserved a profound peace during the last years of his glorious reign. Alfred, who is considered as the founder of the English monarchy, held the reins of government about thirty years. He died in 901, in the 52d year of his age, and was succeeded on the throne by his youngest son Edward.

Alfred.

Alfred may be regarded as one of those prodigies of intellectual endowment which has no equal in the age and country in which he lived. No monarch ever acquired or merited the love, esteem, and veneration of his subjects more than Alfred; and not only on account of the dazzling qualities of his military character, but by an irresistible impulse of gratitude and admiration—gratitude for the inestimable benefits of his civil administration—and admiration of the amiable virtues of his private character. Many of the most useful domestic arrangements and some of the wisest political institutions, derive their origin from him. The naval power was improved and extended, and the militia regulated and strengthened; a code of laws, which is supposed to have been the foundation of the common law of England, was drawn up under his authority; courts and well qualified judges were appointed; the kingdom was divided into counties, hundreds, and tythings; commerce and manufactures were introduced and encouraged; the instruction of the people was promoted; schools and colleges were endowed at Oxford; and scholars were invited to his court.

Although it is stated that Alfred was in his 12th year before a proper person could be found to instruct him in the elements of learning, yet he became eminent as a grammarian, mathematician, and historian; was esteemed the best Saxon poet of his time, and composed in verse various parables and fables for the instruction of his people. He translated the fables of Æsop; the Consolation of Philosophy by Boethius; Bede's Ecclesiastical History, and, it is said also, the Old and New Testaments. The regular distribution of time which Alfred observed, affords a useful lesson to the studious and industrious. The 24 hours were divided into three parts; eight hours were allotted to devotion and literary pursuits; eight were devoted to public affairs, and eight were occupied at his meals, in sleep, and exercise. To note these divisions of time, six wax candles, each of which burnt four hours, were employed during the 24. Each candle was 12 inches long, and each inch, which was consumed in the third part of an hour, was marked with a circular coloured line; and to insure their equal combustion, they were inclosed in horn lanterns, for the purpose of protection in windy weather. The care of these candles was entrusted to the keepers of his chapel, who gave notice of the lapse of time.

The expenditure of Alfred was subjected to a similar methodical arrangement. One part was devoted to charitable purposes, and divided into four portions; the first for alms to the poor, the second for the relief of indigent monks, the third for the support of monasteries, and the fourth for the maintenance of professors and students. The other half was divided into three parts; the first was applied to the expenses of his household, the second for the payment of ingenious artists, and the third to learned foreigners who had been invited into the kingdom.

ALGAE, Flags, the third order of the Cryptogamia, or 24th class of the Linnean system, including under it sea-weeds and some other aquatic plants.

ALGAROTTI, Francis, an Italian author of considerable celebrity, was born at Venice in December 1712; was educated at Bologna; and, during his travels in France and England, became attached to the Newtonian philosophy, of which he published a popular illustration, entitled *Newtonianism for the Ladies.* At Berlin he acquired the favour and friendship of Frederic, king of Prussia, who honoured him with the title of Count. He published also some ingenious speculations on light and colours, possessed considerable critical knowledge in music, painting, sculpture, and architecture, and contributed much to the reformation and improvement of the Italian opera. His works afford ample testimony of his genius and erudition, and they are often distinguished by elegant composition and lively sallies of wit; but the vanity, affectation, and selfishness of his character were intolerable. Perhaps no better proof is needed, than the ambiguous inscription which he composed, and which was inscribed on the tomb erected by himself at Pisa: *Hic jacet Algarottus, sed non omnis:* Here lies Algarotti, but not the whole of him,—may refer, either to his belief in the immortality of the soul, or to the lasting reputation to which he flattered himself his works were entitled. He died at Pisa, in May 1764.

ALGARVA, the most southern province of Portugal, is bounded on the south and west by the Atlantic ocean; on the east by the river Guadiana, which separates it from Spain; and on the north by a mountainous ridge, which forms the division between it and Alentejo. In some places it is tolerably fertile, producing oil, wine, and fruits. The population is between 60,000 and 70,000; and the inhabitants on the sea-coast, who are engaged in fisheries, are the best mariners in the kingdom.

ALGEBRA, or Universal Arithmetic, from its more extensive application than common arithmetic, is employed in discovering the relations which exist among different quantities, in respect of their magnitudes. See Mathematics.

ALGEZIRAS, or Old Gibraltar, a sea-port town of Andalusia in Spain, situated on the coast of the straits of Gibraltar. By this town the Moors entered Spain in 713, and they were expelled from it in 1344, on which occasion, it is said, cannon were first employed. Algeziras is about 10 miles distant from Gibraltar.

ALGIERS, a kingdom of the northern part of Africa, stretching along the coast of the Mediterranean, and including the ancient Numidia and a portion of the ancient Mauritania, is usually considered as one of the states of Barbary. See Barbary.

ALGIERS, supposed to be the ancient Icosium, is the capital of the kingdom of Algiers, derives its name from the Arabic, which signifies *the island*, in consequence of the island before the city, which is now united to it by a mole or pier; and from its situation on the declivity of a hill, and arrangement in the form of an amphitheatre, presents, when seen from sea, a grand and striking spectacle. Excepting the principal street, which runs from east to west, and contains the best shops and warehouses, the streets of Algiers are narrow, incommodious, and dirty. The whitened roofs of the houses rising in regular gradation, exhibit some resemblance to the top-sails of a ship; and their flatness affords an easy communication for the whole length of a street. The houses have a square court in the middle, are constructed with galleries all round, rise to a considerable height, and are furnished with very small windows. The palace of the Dey, and some of the mosques, are the chief public edifices; but they are more distinguished by their magnitude than remarkable for beauty or elegance. The public baths, as is usual in Turkish towns, are numerous. A spring, issuing from a neighbouring hill, supplies Algiers with water, which is conveyed in pipes, and discharged from many public fountains, and each house is provided with a cistern for the reception of rain-water. The town of Algiers is surrounded with walls; has five gates, which are constantly shut during the night; and is farther protected by seven castles, which are well furnished with great guns.

The harbour of Algiers is commodious; the mole extends 500 paces from the land to the island, from which the name is derived; and is protected by a castle and strong battery, erected on this insular spot. Although Algiers is described as being only half a league in circumference, the population is stated, perhaps on no certain authority, at 120,000; of whom one half consists of Moors or Berebbers, 16,000 are Turks, 30,000 are Cologlies, or descendants of Turks and Moors; and Jews, Christians, and renegadoes, make up the remainder.

ALGONQUINS, a race of Indians in North America, which formerly spread over great part of Lower Canada. This race exists now only in small tribes; and, from the precarious nature of their subsistence, which is derived from fishing and hunting, is fast diminishing.

ALHAMBRA, signifying the *red house*, is the ancient palace of the Moorish kings in the city of Granada in Spain, is situated on one of the hills on which the city is built, was begun in 1280 by the second Moorish king of Granada, and was completed by his successors, each of whom added something to its extent and beauty. The lofty situation of the Alhambra affords a wide view of a fertile country. The external aspect of this palace presents a huge mass of uncouth buildings, thrown together without order and without design; and it should be regarded as a singular production, both in the style of its architecture and the character and arrangement of its ornaments. But the interior, with its marble pavements, numerous baths and fountains, fret-work in stucco, and mosaic work on the walls and cielings, groups of columns, and painting in gold and azure, exhibits altogether a magic scene, or a kind of fairy-land. Connected with one side of the ancient palace, a grand edifice, two hundred Spanish feet square, in a very magnificent style, was erected by the emperor Charles V. but it was left unfinished. For an account of the Alhambra, the reader is referred to Swinburne's *Travels*, in which are given drawings of the principal parts, without which scarcely any description could be rendered intelligible.

ALI, a remarkable character in Mahometan history, was the son of Abu Taleb, and cousin of Mahomet, with whom he early and ardently co-operated in the establishment and propagation of the new religion; and, on account of his zealous services, he was hailed by Mahomet as his vizier or assistant, his brother and vicegerent. He was greatly distinguished by his eloquence, and not less celebrated for his valour, which obtained for him, according to the bold metaphorical expression of Eastern languages, the surname of the *Lion of God, always victorious.* Ali had married the daughter of Mahomet; and from this connexion, as well as being his nearest relation by blood, aspired at being his successor; but Abu Beer, the father-in-law of the prophet, and two others, Omar and Othman, reigned before him. The death of Othman opened his way to the sovereignty, which he at first declined, and was only prevailed with to accept of it by the entreaties of his friends and the threats of the people; but his short reign, of scarcely five years, was incessantly harassed by insurrections and rebellions, excited and supported by formidable competitors. He was wounded by the hand of an assassin with a poisoned weapon at the door of the mosque, and he died in a few days, in the 63d year of his age, in the year 660 of the Christian era, and the 40th of the Hegira. The followers or sect of Ali regard him and his descendants as the only legitimate successors of Mahomet, and consider all the caliphs who are not of this family as usurpers. A green turban is their distinguishing characteristic. The Persians are the chief adherents of this sect, and the Turks belong to the sect of Omar, and hold Ali and his followers in execration.

ALI BEY, an eastern adventurer, was a native of Mount Caucasus; and about the age of 12 or 14 was sold as a slave in Cairo, and purchased by two Jews, who presented him to Ibrahim, an officer of the janizaries, and at that time one of the leading men in Egypt. This country was then under the government of twenty-four beys, eight of whom had been selected from the household of Ibrahim. Ali, growing in favour with his master, obtained his freedom; was first appointed to the government of a district, and afterwards elected one of the twenty-four beys. The death of Ibrahim, in 1757, opened a wide field for his ambition, and led him to aspire after the entire sovereignty of the country; but the failure of his first attempt obliged him to retire for safety into Upper Egypt. After an absence of two years, he returned suddenly to Cairo; and in one night he either put to death or expelled those beys who were his enemies. He banished the Turkish pacha,—set the authority of the Ottoman Porte at open defiance,—fitted out vessels on the Red Sea,—seized on the port of Djedda, and plundered Mecca. Ali next formed a plan for the conquest of Syria; and uniting his forces in 1770 with Daher, another rebellious insurgent against the Porte, besieged Damascus. The city was taken; but the castle was saved by the treachery of Mohammed Bey, Ali's commander, who suddenly drew off his forces, and retired to Egypt. An open war now commenced between Ali and Mohammed; and after a long struggle, and various success, Ali was wounded and taken prisoner, was carried to Mohammed, and died in three days, either in consequence of his wound or of poison. This bold adventurer possessed considerable talents and great intrepidity. The vigour of his administration in the suppression of plunderers and robbers, gave greater security to Egypt than it had hitherto enjoyed; but he was rash and impetuous, and his excessive confidence in some of his adherents and favourites ruined his schemes.

ALIBI, a Latin word, which signifies *elsewhere,* is a term employed in the criminal law of this country; as, when a person charged with a crime attempts to prove that he was in a different place, or elsewhere, when it was committed, or pleads an *alibi.*

ALICANT, a sea-port town of Valencia, in Spain, is situated on a narrow neck of land, which projects a considerable way into the sea, and is protected by a strongly fortified castle, on the summit of a rocky mountain, which rises behind the town. At the beginning of the 16th century, six houses only stood on this spot; but before its termination it contained more than 1000, owing, it is said, to its secure situation from the depredations of pirates, who then infested the coasts of the Mediterranean. The population is stated at 17,000; and the principal trade is in barilla, fruit, and wine, especially the famous *tent wine.* Alicant is 75 miles S. of Valencia, and 37 N.E. from Murcia; in N. Lat. 38° and W. Long. 0° 24′.

ALICATA, the ancient LEOCATA, a town of Sicily, situated on a peninsula, in the valley of Mazara, contains about 10,000 inhabitants, and has a considerable trade in corn and wine. It is 22 miles S. E. from Girgenti.

ALICUDA, one of the Lipari isles, on the northern coast of Sicily, contains about 500 inhabitants, whose houses are built at considerable elevations on the declivity of the mountains. The chief productions of this island are Indian figs, olive trees, and vines, which afford an excellent wine, with some barley and wheat. No springs of fresh water are found on the island, so that the inhabitants suffer great inconvenience and distress during a long course of drought. Alicuda is considered by some geologists as a volcanic production.

ALIEN, from the word *alienus,* which signifies a stranger or foreigner, is a person born out of the kingdom, and under the dominion of a foreign government. In this country peculiar laws have been enacted with regard to aliens. By the law of Scotland, no alien is capable of acquiring or succeeding to heritable property, without being naturalised by an act of parliament. No alien can vote for a member of parliament, or sit in the house of commons; but children born in a foreign country, whose fathers are citizens, or natural born subjects at the time of the birth of their children, are regarded as natural born subjects of Great Britain, unless by treason or felony, or being in the service of a foreign state at war with Britain, the fathers have forfeited their privileges.

ALIENATION is the act of making over or disposing to another person the property of lands, tenements, &c. Alienation in fee, is the transference of the fee-simple of any land or other right. Alienation in mortmain, is the transference of lands or other heritage to a religious house, or corporation, which is not permitted without a licence from the king.

ALIMENT, or ALIMENTS, are those substances, whether of a vegetable or animal nature, which are destined for the nourishment of animals. See DIETETICS.

ALIQUANT PART, is a number which cannot measure a greater number without a remainder: thus, 4 is an aliquant part of 13, because three times 4 is 12, and is deficient by one; and 4 times 4 is 16, and exceeds the number by three.

ALIQUOT PART, is that part of any number or magnitude which divides it without a remainder: thus 3 is an aliquot part of 18, and 8 of 24.

ALISMA, Water Plantain, a genus of plants belonging to the Hexandria class, of which four species are natives of Britain.

ALKAHEST, or ALCAHEST, signifying *all spirit*, or *spirit of salt*, was one of the great objects among the pursuits of the alchemists, and denotes the *universal solvent* which possessed the property of resolving all bodies into their first principles, or of dissolving all substances into a simple uniform fluid.

ALKALI, is applied to a class of bodies which have a peculiar acrid taste, have a strong affinity for water, and combine with it in large proportion, change vegetable blue colours to green, and brown colours to yellow; corrode animal substances, and unite with oily and fatty matters, and form soaps, and with acids forming neutral salts. Three substances, potash, soda, and ammonia, possess these distinct properties. Two of them, potash and soda, are called *fixed alkalis*, because they require a very strong heat to volatilize them; and ammonia is denominated *volatile alkali*, because, with a moderate heat, it assumes the gaseous form. The recent discoveries of Sir H. Davy, which constitute a brilliant era in chemical science, have shewn that the alkalis are oxides of peculiar metals, or are compounds of a metallic base and oxygen. See CHEMISTRY.

ALKERMES, an old term for a cordial confection, deriving its name from the kermes berries employed in its composition.

ALKOHOL, or spirit of wine, a colourless transparent liquid, which is the product of the distillation of fermented liquors, as wine or beer. See CHEMISTRY.

ALKORAN, or the KORAN, the Scriptures of the Mahometans, containing their doctrines and precepts as they were revealed to the prophet. See KORAN.

ALL-SAINTS, or ALL-HALLOWS, a festival held on the first of November by the Church of Rome, as a general commemoration of the saints; introduced into Italy in the 9th century by Boniface IV. and soon after adopted in other churches.

ALL-SAINTS, a spacious harbour or bay on the coast of Brazil in South America, is about eight miles broad, and is studded with numerous small islands. It is also the name of a rich and fertile district of Brazil, which produces great quantities of cotton and sugar, and contains several town and cities, of which St. Salvador is the capital. All-saints bay is in S. Lat. 12° 3'. and in W. Long. 40° 10'.

ALL-SOULS, a festival of the Romish Church celebrated on the 2d of November, in commemoration of all the faithful deceased, was first introduced in the 11th century.

ALLA, or ALLAH, the name by which the Supreme Being is addressed by the followers of Mahomet, is derived from the Arabic verb, *alah* to *adore*, and is synonymous with the Hebrew *Eloah*, signifying the *Adorable Being*.

ALLAHABAD, a province of Hindostan, including a space of more than 19000 square miles, is bounded on the east by the province of Bahar, and on the north by that of Oude; according to its ancient division, is distributed into ten circars; formerly contributed to the public service nearly 250,000 troops; and the greater part of it is now under the dominion of the British power. The principal cities are Allahabad and Benares.

ALLAHABAD, the capital of the province of the same name, is supposed by Dr Robertson to be on the site of the ancient Palibothra, while Major Rennel thinks that Patna is built on the spot formerly occupied by that famous city. Allahabad is situated at the confluence of the Ganges and Jumna, and is divided into the *old* and *new* towns; the former stands on the banks of the Ganges, and the latter on those of the Jumna. The fortress, erected by the emperor Akbar, and occupying a large space within the city, a pillar of a single stone, 40 feet high, and the splendid tomb of the Sultan Khufru, afford excellent specimens of oriental architecture. Allahabad is held in high veneration, is distinguished by the name of "the king of worshipped places," is the great resort of pilgrims, and the space of 20 miles round the city is deemed holy ground. N. Lat. 25° 27'. E. Long. 82° 5'.

ALLAN, DAVID, an eminent historical painter, who has been sometimes designated the Hogarth of Scotland, from the peculiar character of some of his productions, was born at Alloa in February 1744. The early indications of mechanical dexterity which he exhibited with no other instrument than a knife, attracted the notice of Mr Stewart of the customs, in his native place, and obtained for him, from that gentleman, a recommendation to the academy of painting, under the superintendence of the Messrs Foulis, the celebrated printers at Glasgow, where he was admitted and remained seven years. The liberality of Mrs Erskine of Mar, Lady Charlotte Erskine, Lord Cathcart, and Mr Abercromby of Tullibody, enabled the young artist to visit Italy, and to study the sublime productions of the pencil and the chissel in the imperial seat of the fine arts. The generous kindness of his patrons was not disappointed; for in 1773 he produced the best specimen of historical composition, the subject of which was the Origin of Painting, and obtained the prize medal of the academy of St. Luke at Rome.

After a residence of 16 years in Italy, Mr Allan returned to Scotland, and was appointed master of the academy for drawing and painting established in Edinburgh by the Trustees for Manufactures, &c. Beside the ordinary duties of his situation, the illustrations of the popular pastoral, the Gentle Shepherd, the Scottish Wedding, the Highland Dance, the Repentance Stool, and the Cottar's Saturday Night, from the poem of our immortal bard Burns, are enumerated among the admired productions of his pencil; and those who are acquainted with Scottish manners can fully appreciate the characteristic touches and delicate humour which abound in those pictures. The Prodigal Son, in the possession of Lord Cathcart, and Hercules and Omphale, in the possession of Mr Erskine of Mar, are also favourable specimens of his professional talents. The private character of Mr Allan, which was distinguished by amiable and unaffected manners, procured him the respect and attachment of his friends while he lived, and their unfeigned regret followed him to the grave, in August 1776, in the 53d year of his age.

ALLANTOIS, a membrane which invests the fœtus of quadrupeds, is of a thin structure, and lies between the amnios and chorion.

ALLEGHANY MOUNTAINS, sometimes denominated *Appallachian* from a tribe of Indians occupying the banks of the Appalachicola river, is an extensive elevated ridge intermediate between the Atlantic ocean on the one hand, and the Mississippi and the lakes of North America on the other. This mountainous range, stretching south-west and north-east, commences in Georgia, runs through Virginia and Pennsylvania, and terminates in New Brunswick. The whole length of the chain is stated at 900 miles, and the breadth, including the different ridges, varies from 70 to 150 miles. The greatest elevation, about 8000 feet above the level of the sea, is in New Hampshire. The sources of different rivers, some of which terminate in the gulph of Mexico, and others run into the Atlantic ocean, are traced to the Alleghany mountains.

The geological constitution of the Alleghany mountains affords examples both of the primary and secondary strata of rocks; granite, gneiss, micaceous, and argillaceous schistus, occupy the central and usually the more elevated parts of the chain; sandstone, limestone, with animal remains, and gypsum, are the prevailing rocks in the lower ranges; and extensive alluvial depositions have been formed in the vallies and flat country. The slaty strata are occasionally the respositories of silver, copper, and lead.

ALLEGHANY *County*, forms the western division of Maryland in North America, and is bounded by Pennsylvania on the north, by the river Potomack and Virginia on the south; contains a population of nearly 9000, and the chief town is Cumberland. Alleghany is also a county in Pennsylvania, the population of which exceeds 10,000, and Pittsburgh is the chief town.

ALLEGHANY *River*, rises from the west side of the Alleghany mountains, and after a course of 200 miles joins the Monongahela at Pittsburgh, and their united streams form the Ohio.

ALLEGIANCE, derived from a word which signifies *to bind*, denotes the legal tie by which the subject is bound to his sovereign or liege lord. The name and the form of this obligation are derived from our Gothic ancestors; but the nature of government, or the mutual connexion which subsists between the ruler and the ruled, or the king and his subjects, implies such an obligation. Under the feudal system, every owner of lands held them immediately of the sovereign himself, or of his vassals; and hence a mutual confidence arose between the lord and the vassal, that the lord or superior on the one hand should protect his subject or vassal in the enjoyment of his property, and that the vassal should be faithful to his lord, and defend him against his enemies. The obligation on the part of the vassal was expressed or acknowledged in the oath of fealty, which was required by the feudal law to be taken by all tenants to their sovereign or superior lord.

Allegiance, both expressed and implied, is distinguished by the law into *natural* and *local*. Natural allegiance is due from all men born within the king's dominions, immediately upon their birth, for then they come under the king's protection. Local allegiance is due from an alien, or stranger born, as long as he continues under the king's dominion and protection. Natural allegiance is regarded as a perpetual obligation, but local allegiance is only temporary. The oath of allegiance is in the following terms: "I, A. B. do sincerely promise and swear, that I will be faithful, and bear true allegiance to his Majesty King George," and may be tendered to all persons above 12 years of age, whether natives or foreigners, in the sheriff's court, or in the court leet of the manor; but the simple declaration of Quakers is admitted as a substitute for the formality of the oath.

ALLEGORY, is a figurative mode of writing, which consists in selecting a secondary subject, in which the chief circumstances bear some resemblance to the principal subject, and thus contributes to its illustration. Allegorical writing has been not unaptly compared to emblematical painting, in which an exercise of the mind, by reflection and meditation, to discover the meaning and application, is required; and in this way instruction and amusement are combined. The 80th psalm, in which a vineyard is made to represent God's own people the Jews, has been often quoted as an example of a beautiful and correct allegory. The address of Nathan to David, in 2 Sam. chap. xii. is another excellent illustration of allegorical composition.

The progress of human life is finely represented in an allegory, under the figure of a voyage, in the following beautiful verses by our celebrated poet Cowper.

Thou, as a gallant bark from Albion's coast,
(The storms all weather'd, and the ocean cross'd)
Shoots into port at some well-haven'd isle,
Where spices breathe, and brighter seasons smile;
There sits quiescent on the floods that show
Her beauteous form reflected clear below,
While airs, impregnated with incense, play
Around her, fanning light her streamers gay;
So thou, with sails how swift! hast reach'd the shore,
"Where tempests never beat nor billows roar."
And thy lov'd consort on the dang'rous tide
Of life, long since, has anchor'd at thy side.
But me, scarce hoping to attain that rest,
Always from port withheld, always distrest—

Me howling winds drive devious, tempest-toss'd,
Sails ripp'd, seams opening wide, and compass lost;
And day by day some current's thwarting force,
Sets me more distant from a prosperous course.

ALLEGRI, Antonio, designated Corregio, from the place of his birth, an eminent painter, was born in 1494; and merely by the force of his own genius, unaided by wealth or patronage, acquired that lasting fame which his own age denied, but which posterity has amply awarded. The scantiness of his means precluded him from visiting Rome. Parma was the chief place of his residence, where he was employed to paint the cupola of the cathedral. The subject is the assumption of the Virgin; and when it was finished, the canons, through ignorance or avarice, found fault with the work, and paid him only 200 livres, a smaller sum than the stipulated price of his labour. This harsh and unfair treatment threw him into a fever, which in three days terminated his life and misfortunes, in 1534, and in the 40th year of his age. The admiration and applause of Annibal Caracci, who flourished 50 years after Corregio, afford the most undoubted testimony of the excellence of his productions. "Every thing I see here," he says, "astonishes me, particularly the colouring and beauty of the children. They live, they breathe." And the magnificent painting on the cupola of the cathedral was admired by the celebrated Titian, to whom, indeed, its preservation is ascribed; for so little was the merit of the performance understood, that the canons expressed to him their intention of having the whole defaced. With some degree of vanity, he replied, "Take care what you do; if I were not Titian, I would certainly wish to be Corregio."

ALLEGRI, Gregorio, a celebrated composer of music, and chiefly of church-music, flourished in the 17th century, was a native of Rome; was appointed, in 1629, one of the singers of the Pope's chapel, and became eminent by the simplicity and purity of the harmony of the church services which he composed. His most distinguished production is the *Miserere*, which continues to be annually performed in the pontifical chapel, on Wednesday and Good Friday in passion week, by the choral band and the principal singers of Italy. But the solemnity of the ceremonies observed during the performance, it is justly supposed, adds not a little to the impressive grandeur of the whole. "The pope and conclave are all prostrated on the ground; the candles of the chapel, and the torches of the ballustrade, are extinguished one by one, and the last verse of the psalm is terminated by two choirs; the master of the chapel beating time slower and slower, and the singers diminishing, or rather extinguishing the harmony by little and little to a perfect point." The private character of Allegri was amiable and excellent. The poor were bountifully relieved by his charity, and the prisoners derived comfort from his kindness and beneficence in his daily visits to their dreary abodes. He died in 1652.

ALLEGRO, a musical term, denoting that the part which is thus marked is to be performed in a brisk and gay manner.

ALLEIN, Joseph, a nonconformist divine, was a native of Wiltshire, was born in 1633, educated at Oxford, and was settled, in 1655, in Taunton Magdalen, in Somersetshire; but, on account of his principles, was deprived of his living. He died in 1688, at the early age of 35. One of his religious works, entitled *Alarm to unconverted Sinners*, had an extraordinary circulation. Twenty thousand copies of an edition published in 1672 were sold; three years afterwards, in 1675, the almost incredible number of 50,000 were disposed of under the title of *A Sure Guide to Heaven*, and a large impression with the original title in 1720.

ALLEYN, Edward, a celebrated English actor in the reigns of Elizabeth and James her successor, and founder of Dulwich college in Surrey, was born in London in 1566. He was the cotemporary of Shakespeare, an original actor in some of his plays, and seems to have lived on the most friendly habits with the poet, as well as with Ben Johnson. Alleyn amassed a large fortune by his profession, in which he rose to considerable eminence. In the quaint language of one of his biographers, he is described as a "Proteus for shapes, and a Roscius for a tongue." But it was not solely to his own individual dramatic efforts that he was indebted for the wealth which he accumulated. He was manager and proprietor of a theatre which he built at his own expense; and he derived an annual revenue of L. 500 from the place of keeper of the king's wild beasts, or master of the royal bear garden. The buildings of Dulwich college, begun in 1613, under the superintendence of the celebrated architect Inigo Jones, were finished in three years, at an expense of L.10,000, and lands to the amount of L.800 a-year were appropriated for the support of the institution, which was destined for the maintenance of a master and warden, who were always to be of his name, and four fellows, three of whom must be clergymen, and the fourth a skilful organist, beside six poor men, an equal number of women, and 12 poor boys, who were to be educated till the age of 14 or 16, and then placed in some trade. It is a curious fact in the history of this institution, that the charter for the appropriation of the lands intended for its support was for some time retarded by lord chancellor Bacon, who wisely recommended to the king to devote part of the funds to the establishment of two academical lectures; and it was not till 1619 that the royal licence was obtained, and publicly announced in the new chapel of the college, which is denominated the *College of God's Gift*; and it is not less curious that the founder became the first master, and submitted to the economical arrangement which he had formed for the institution. But while he restricted his enjoyments, he was not unmindful of worldly affairs; for he still continued in the lucrative management of the theatre; and, besides this college, which continues to flourish, he made suitable provision for the support of several alms-houses in London and Southwark.

The following letter, which appeared in the Annual Register for 1770, contains a singular anecdote of Alleyn and his dramatic friends, who used to spend their evenings at the sign of the Globe, near Blackfriars, and in the vicinity of the play-house. It is addressed to a friend by G. Peele, a fellow of Christ Church college, Oxford, and a dramatic writer, who was a member of the club.

"Friend Marle,—I never longed for thy company more than last night: we were all very merry at the Globe, when Ned Alleyn did not scruple to affyrme pleasantely to thy friende Will, that he had stolen his speech about the qualityes of an actor's excellencye in Hamlet his tradgedye, from conversations manyfold whych had passed betweene them, and opinyons given by Alleyn touchinge the subjecte. Shakespeare did not take this talke in good sorte; but Johnson put an ende to the strife with wittylye remarkinge, *This affaire needeth no contentione; you stole it from Ned, no doubt; do not marvel: Have you not seen him act tymes out of number?* Yours, G. Peele."

Alleyn died in 1626, in the 61st year of his age, and was buried in the chapel of his own college, where a tombstone, with an inscription, marks his grave. The original Diary of this remarkable character, it is said, is still preserved in the college.

ALLIA, a river of Italy, whose stream joins the Tiber, four miles from Rome. The Romans sustained a dreadful disaster on the banks of this river, when an army of 40,000 was either slain or put to flight by the Gauls under Brennus; and hence it is remarked by Cicero, that their ancestors deemed the battle of Allia a more fatal event than that of taking the city.

ALLIANCE, is a relation contracted between two persons or families by marriage; but, in a political sense, it denotes an obligation entered into by sovereigns or states for their mutual safety and protection. *Offensive* alliance is when the contracting parties bind themselves to make war upon the common enemy; and *defensive* alliance when they assist each other to repel his attacks.

ALLIER, a department of France, formerly the province of Bourbonnois, derives its name from the river which traverses it from north to south; has the department of the Loire on the east, contains nearly a million and a half of square acres, and about 270,000 inhabitants; includes some extensive forests, and is celebrated for its mineral waters at Vichy and Bourbon, places of great resort in spring and autumn. The fish taken in the lakes and marshes of this department form a considerable branch of trade.

ALLIGATION is an arithmetical operation, by which questions which relate to the mixture of one ingredient with another of different weight and value are solved. See ARITHMETIC.

ALLIGATOR, the specific name of the American crocodile, derived from the Spanish word which signifies a lizard. See *Lacerta*, under ERPETOLOGY.

ALLIONIA, a genus of plants belonging to the Tetrandria class.

ALLITERATION is the repetition of the same letter at the beginning of words or syllables at certain intervals; it is chiefly, although not exclusively, employed in poetical compositions, and is considered by some as an ornament of language, while others regard it as a trifling and false refinement. Some critics ascribe the pleasure derived from alliteration to a mechanical operation, or to the facility of articulating similar sounds; and others conceive that it is to be traced solely to the gratification of the ear derived from the frequent recurrence of the same sounds. Perhaps, if rightly investigated, the effects of alliteration depend on the operation of both causes. Alliteration is in frequent use with the best English poets. In the following examples the alliterative letters are in italics.

*B*ehemoth *b*iggest *b*orn.—MILTON.

*S*oftly, *s*weet, in Lydian measures,
*S*oon he *s*ooth'd the *s*oul to pleasures.—DRYDEN.

Eternal beauties grace the *s*hining *s*cene,
*F*ields ever *f*resh, and *g*roves for ever *g*reen.—POPE.

*R*uin seize thee, *r*uthless king.—GRAY.

That hush'd in grim re*p*ose ex*p*ects his evening *p*rey.—IBID.

Nor cast one *l*onging, *l*ingering *l*ook behind.—IBID.

ALLIUM, a genus of plants, including the onion, leek, and garlic, and belonging to the Hexandria class.

ALLOA, a sea-port town on the north side of the Frith of Forth, and in the county of Clackmannan, in Scotland, has been long a place of some note in Scottish history. The massy tower in the vicinity, which is 90 feet high, was erected about the end of the 13th century, and seems to have been at one period a royal residence; for, in 1365, the lands and tower of Alloa were exchanged by David II. king of Scotland, with Thomas Lord Erskine, and has since continued to be the residence of the family of Marr, who were long guardians of the princes of Scotland. The cradle of Henry prince of Wales, the last heir of the Scottish monarchy, and the child's chair of James VI. are still preserved in the tower. The pleasure-grounds of this ancient residence were laid out in the French style in the beginning of the 18th century.

The harbour of Alloa is safe and commodious, and has the advantage of a dry dock, capable of admitting large vessels. The manufacture of common glass bottles is extensive; but the coal mines, some of which have been wrought for nearly 200 years, and the distilleries in the neighbourhood, are the chief sources of the trade of Alloa. Thirty-five thousand tons of coals have been exported in the course of a year; and in 1806, more than 1,000,000 gallons of whiskey were shipped. The chief imports are grain, limestone, ironstone, and wood and iron from the Baltic. The population of Alloa is about 3000, and the distance from Leith is about 20 miles.

ALLODIAL is applied to lands which are held by a person in his own right, without any service or acknowledgment to a superior.

ALLOY is the combination of two or more metals, by which the properties of the individual metals are changed, and new properties, which render the compound extremely valuable in the arts, are obtained. Alloy is also employed to signify the proportion of a baser metal, which is mixed with gold and silver, for the purpose of coin. In the gold coin of this country, silver and copper are used as the alloy, and it is estimated by carats. Standard gold contains 2 carats of alloy, and 22 carats of fine gold. Copper alone is the alloy of the silver coin; and standard silver contains 18 dwts. of copper alloy, and 11 oz. 2 dwts. of fine silver.

ALLUVION, denotes the gradual increase of land on the banks of rivers, or on the sea-shore. When the addition has been effected slowly and imperceptibly, the land thus obtained belongs to the proprietor of the ground to which the addition is made; but, in case of sudden and violent changes, as by a convulsion of nature, or the alteration of the course of a river, the separated land belongs to the original proprietor.

ALMACARRAN, a sea-port town in the province of Murcia in Spain, in the neighbourhood of which is found a red ochre, which is employed in painting, and as an ingredient in Spanish snuff. The rocks in the vicinity afford abundance of aluminous ore. It is 20 miles west of Carthagena.

ALMADEN, a town of La Mancha in Spain, which has been long celebrated for its quick-silver mines, which began to be wrought by Germans before the middle of the 17th century. The ore is cinnabar, or native vermilion; and twelve furnaces, which are whimsically called the twelve apostles, are employed in refining it. Almaden contains above 300 houses, and the inhabitants are chiefly occupied in the mining establishment. Almaden is 44 miles north from Cordova.

ALMAGEST, is particularly applied to a work which is ascribed to Ptolemy, and which contains various problems in Geometry, and observations on astronomy, and a catalogue of the fixed stars. This collection was found at Alexandria, and was translated by the orders of Almamon into Arabic, in 827; and the original Greek text, which was discovered at Constantinople, has been translated into Latin. The same title has been used by others, as in a book of astronomy by Riccioli, which is called the *New Almagest.*

ALMAMON, a distinguished caliph of Bagdad, and a celebrated astronomer, was born in the year 786. His reign was disturbed by those insurrections and rebellions which were common in the countries over which he ruled. His name is chiefly worthy of being transmitted to posterity as the liberal patron of literature and science. In early life, and before he ascended the throne, he established an academy, and invited the learned men of different nations to his territories to become the teachers of youth. Unshackled by the prejudices of the times, he placed a Christian physician from Damascus at the head of his institution. Astronomy was cultivated in the time of his grandfather Almansor, who was the second caliph of the Abassides; Almamon continued to encourage and promote the same study, and was himself no mean proficient in that sublime science. The obliquity of the ecliptic was observed in his time, and the geometers whom he liberally supported were employed in the measurement of a degree of the meridian on the plains of Mesopotamia. To facilitate the more rapid and extensive diffusion of knowledge, the best works on various subjects were translated from different languages. This wise and liberal sovereign, having reigned more than 20 years, died in the 49th year of his age.

ALMANACK, from the Arabic words *al* and *manack*, which signify *the Diary*, is a book or table containing a kalendar of days and months, rising and setting of the sun, age of the moon, eclipses, &c. As the construction of tables of this description depends on astronomical observation, almanacks are supposed to have been first drawn up by the Arabians, among whom astronomy flourished. Regiomontanus, the astronomer, reduced almanacks to their present form and arrangement in Europe. His first almanack was published in 1471.

ALME, or ALMEH, a class of women who have devoted themselves to the practice of singing, recitation, and dancing, in Egypt and other eastern countries, and are accustomed to extemporaneous poetical effusions, on subjects of immediate occurrence. The Almé of Egypt form a celebrated profession to which those only who are properly qualified are admitted. For this purpose, beside being carefully instructed in the arts of singing and dancing, they must possess an accurate knowledge of the language, and acquire a facility of composing verses without premeditation.

The Almé form a part of all festive entertainments, and they are employed as fictitious mourners at funeral solemnities: Different orders of the Almé are found who accommodate their performance to the rank of society before whom they exhibit. The higher orders are well educated, and of a polished character; but those whose exhibition is confined to the lower ranks of the people, are little distinguished by correctness of conduct or delicacy of manners; and there are probably few or none of the whole profession that are entirely free from the charge of some degree of licentiousness. Among the Hindoos, the Almé are divided into three classes; the first is devoted to the service of the temples, where dancing is occasionally introduced; the second is called the fashionable class, who are descended from the *cast* or tribe of weavers, whose females have been long destined to this profession; and the third, or lowest class, is composed of women of very inferior accomplishments, and equally indifferent morals.

ALMOHEDES. See Almoravides.

ALMONER, an officer in religious houses, to whom were entrusted the management and distribution of alms to the poor. According to ancient canons, a tenth part of the revenue of monasteries ought to be destined to charitable purposes. The Lord High Almoner of England is an ecclesiastical officer, and usually a bishop, into whose possession all deodands, and the confiscated goods of suicides, fall, for the purpose of being distributed to the poor; and to the same officer, by ancient custom, belongs the power of giving the first dish from the king's table to any poor person he chuses, or in lieu of it a sum of money.

ALMORAVIDES, an Arabic tribe, who retired to a secluded district of Africa for the purpose of observing more rigidly the peculiar precepts of the Koran. They assumed the name of Morabites, which was converted by the Spaniards into that of Almoravides. Abubeker Ben Omar was the first chief, and with the aid of an insurgent army from Numidia and Libya he founded the dynasty in 1051. His son and successor, Joseph, subdued and became master of Morocco, Tunis, and the intermediate territory, crossed the Mediterranean, and reduced many of the kingdoms of Spain to subjection; and in a second invasion in 1107 penetrated into Portugal, as far as Lisbon. Ali his son, who succeeded in 1110, more disposed to cultivate the arts of peace, planned and erected the great mosque of Morocco, and many other public edifices. He was slain in a dreadful battle with Alphonso king of Arragon; and his son, after a luxurious and oppressive reign of 25 years, was driven from his throne, and succeeded by a new dynasty, known in history by the name of Almohedes.

The founder of the dynasty of the Almohedes was Al Mohedi or Mohedes, a Berebber, or native of the mountains, who appeared as a preacher or reformer, and became leader of the orthodox or Unitarians. A clamorous advocate for liberty, and professing unbounded zeal for religion, he soon attracted notice, and formed a party, whose views, as their numbers increased, extended to other objects beside the purity of the faith. A public attempt to suppress them was made by Brahem, the last of the race of the Almoravides; but it proved unsuccessful; he was driven from his capital, pursued as a fugitive, with his favourite wife on horseback behind him, and despairing of escape from his enemies, threw himself over a precipice, where he and his wife were dashed to pieces.

The termination of the dynasty of the Almoravides, was the commencement of that of the Almohedes, of whom the first king was Abdolmumen, a powerful leader of the new party. The constitution of their government was wisely framed to insure popularity; the civil and religious establishments were united in a council of 40 persons, and the sovereign, who was both king and chief priest, was chosen from that number. This dynasty, which continued for 170 years, neglected not the security or extension of their temporal power by means of the sword, both in Africa and Spain. But a disastrous battle with the Christians in the latter country, in which nearly 200,000 Moors fell on the field, weakened the attachments of his native subjects to Al Nahör, the last but one of this race, and in a short time occasioned his death. The assassination of his successor and grandson was the termination of the dynasty.

ALNWICK, the county town of Northumberland, in England, like other border towns, was formerly surrounded with walls, which the fortunate cessation of intestine war has permitted to fall to decay. One of the gates, in the form of a tower, still remains as a memorial of the gallant Hotspur, by whom it was erected. Alnwick is situated on the river Alne, from which the name is derived, contains a spacious square for the public markets and public buildings, and from which the principal streets proceed. The population is nearly 5000; no manufactures of any extent or importance have been established in Alnwick, and its inland situation affords few facilities to trade; but every branch of liberal education is taught in three free schools, which are supported by the public revenue of the town.

The castle, the seat of the chief of the Percy family, and one of the grandest baronial residences in the kingdom, with its extensive and beautiful grounds, forms one of the principal ornaments to the vicinity of Alnwick. This gothic structure has been of late years completely repaired, and the internal decorations have been finished with great elegance and splendour. The chapel, with its painted and gilt mouldings, and stucco work, and fine specimens of painted glass, is much admired. During the residence of the Duke of Northumberland at this princely mansion, the style of old English hospitality is kept up. On certain days the gentlemen of the surrounding districts, and even respectable strangers, are admitted by a kind of tacit general invitation to the table of this noble family.

Alnwick is 84 miles south from Edinburgh, and 310 north from London.

ALOPECURUS, Fox-tail Grass, a genus of plants belonging to the Triandria class, of which several species are natives of Britain, and are cultivated as pasture-grasses.

ALPHABET, a word derived from the names of the first and second letters of the Greek alphabet, denotes the order or series of the letters of any language. See LANGUAGE.

ALPINI, PROSPERO, in Latin, *Prosper Alpinus*, a celebrated physician and naturalist, was a native of the Venetian republic, and was born in 1553; spent part of his early years in the military profession, afterwards studied medicine at the university of Padua, and settled at a small town in the Paduan territory. With a strong inclination for botanical pursuits, he eagerly embraced the opportunity of accompanying the Venetian consul to Egypt, where a residence of three years enabled him to extend his knowledge of plants and of vegetable economy. From observations which he made on the management of date palm-trees in that country, it appears that he deduced the doctrine of the sexual difference of plants, which was assumed as the foundation of the Linnæan system.

Alpini returned to Venice in 1586, was appointed physician to Andrew Doria, prince of Melfi, and at Genoa, where he resided, acquired the reputation of the first physician of the age. But the Venetians, it is said, were jealous that strangers should enjoy the benefits of the professional abilities and reflected fame of their countryman, and recalled him, in the year 1593, to fill the botanical chair in the university of Padua, the duties of which he zealously and faithfully performed. He died in 1617, and was succeeded by his son. Alpini was a voluminous author: He wrote on Medicine in General; on the Practice of Medicine among the Egyptians; on the Plants of Egypt; on Exotic Plants, &c.

ALPS, originally restricted to that range of mountains which separates Italy from France and Germany, may be now considered as a general appellation of highly elevated land; and hence some ancient authors speak of *Spanish Alps*, and among the moderns any mountainous region is so denominated, as *Swiss Alps*, to which the term seems to have been first applied, *Asiatic Alps, American Alps, British and Scottish Alps;* and the phrases *Alpine country* and *Alpine plants*, are quite familiar to naturalists. The word is derived by some from the Latin word *albus*, white, a characteristic expression of their snow-capped summits, and by others it is traced to a Celtic origin, and signifies mountainous pastures, or *highly elevated land*. But the particular description of these mountainous regions falls more properly under the different countries to which they belong.

ALPS, three departments of France, in the immediate vicinity of the mountains from which the name is taken. In the Higher Alps, the rearing of sheep and cattle is the chief occupation of the inhabitants; in the Lower Alps the cultivation of potatoes is very extensive; and the Maritime Alps was an annexation, in 1793, of Nice and the principality of Monaco to France.

ALPUXARRAS, or ALPAXARES, the ancient *Montes Solis*, or Mountains of the Sun, a range of high mountains in the province of Granada in Spain, which occupy a space of 35 miles in length and 15 in breadth, from the city of Velez to Almeria. This elevated region is chiefly inhabited by the Moors who remained after the expulsion of their countrymen from Europe, and, preserving their own manners and language, have embraced Christianity. They are represented as skilful husbandmen, and are very successful in the culture of fruit trees. Among the natural wonders of these mountains are recorded the waters of a spring, probably of a chalybeate quality, which in an instant dye silk or linen, and the exhalations of a cavern, no doubt fixed air or carbonic acid gas, which are noxious to animal life.

ALSACE, a former province of France, now divided into the departments of the Higher and Lower Rhine, is one of the most fertile districts of the kingdom. The lower regions abound in corn, wine, and fruits; and the mountains are clothed with extensive forests.

ALSEN, a Danish island lying in the Lesser Belt, at the entrance of the Baltic, and between the island of Funen and the coast of Sleswick, from which it is separated by a narrow channel. Alsen is 20 miles in length and 10 in breadth. The soil is fertile, and produces grain, fruits, and a great deal of aniseed. The woods abound with game, and the lakes with fish. It is 100 miles west from Copenhagen.

ALSINE, Chickweed, now arranged by Dr Smith under the genus Stellaria, belonging to the class Decandria, was formerly placed as a distinct genus in the Pentendria class. Among the productions of the vegetable kingdom which are affected by changes of the weather, none, perhaps, affords a surer indication of a fair day than the full expansion of the flowers of chickweed in the morning.

ALSTON, CHARLES, a physician and botanist, was a native of the west of Scotland, and was born in 1683, commenced his studies at the university of Glasgow, and, under the patronage of the Duchess of Hamilton, attached himself exclusively to medicine, in the prosecution of which, in his 33d year, he accompanied the first Dr Monro to Leyden, where he continued three years, under the instruction of the celebrated Boerhaave. The return of Monro and Alston to their native country may be considered as a propitious era to the university of Edinburgh; for to them, in conjunction with Sinclair, Rutherford, and Plummer, the origin of its medical school is to be traced. Dr Alston taught Botany and Materia Medica, and rendered himself conspicuous by combating the Linnæan doctrine of the sexual system of plants, in a memoir published in the Edinburgh Physical and Literary Essays. The language he employs in this memoir has not escaped censure, and perhaps merits it. He recommended the use of tin, powdered or granulated, for the expulsion of worms, in another memoir; he entered into a controversial discussion, concerning the properties and effects of quicklime, with Dr Whytt of the same university, and his lectures on Materia Medica were published in two volumes, 4to., ten years after his death, which happened in November 1760, and in the 77th year of his age.

ALSTON, or ALDSTONE MOOR, a town in the county of Cumberland, and in the hilly country on the borders of Northumberland, containing a population of nearly 4000, who are chiefly employed in the lead mines in the vicinity, which have been long celebrated for the abundance of that metal. The lands form part of the forfeited estates of the Earl of Derwentwater, and are held in lease for 1000 years from the governors of Greenwich hospital, to which establishment they were appropriated by the legislature. Alston Moor is 19 miles from Penrith, and 304 north from London.

ALSTONIA, a genus of plants belonging to the Polyandria class.

ALSTROEMERIA, a genus of plants belonging to the Hexandria class.

ALT, a term applied to the high notes in the musical scale, or those between F in the treble cliff note and G in altissimo.

ALTAI, or ALTAY, a range of mountains in the northern regions of Asia, which extend 5000 miles from the 70th to the 140th degree of E. longitude, form the boundary between the Russian territory and Chinese Tartary, and are divided, according to diversity of course or elevation, into the greater and lesser. But beside this general division, numerous branches stretch out in various directions. Some of these mountains are of such a height as to be covered with perpetual snow. They are chiefly composed of primitive rocks. Granite occupies the loftiest part of the range; the slaty rocks, as gneiss and schistus, are found in the intermediate division; and strata of limestone and marble are deposited in the lower regions. The Altaian mountains are the copious repositories of various metallic ores, as gold, silver, copper, lead, and iron, and some of them have been extensively wrought, of which some notion may be formed from the number of persons, exceeding 50,000, employed in the different operations.

ALTAR, a structure on which sacrifices were offered to some deity, was made of various forms and materials. Altars are supposed to be coeval with sacrifices themselves. While some date the origin of altars in the time of Adam, others think that Enoch was the first who consecrated a public altar; but the earliest testimony concerning altars referred to those erected by Abraham. Of the simplicity and rude form of altars in the patriarchal times, what is recorded in Scripture of the stone which had served Jacob for a pillow, and which he set up in Bethel, furnishes a striking example.

Among the ancients, the word *ara*, in its more general signification, included every kind of altar. But a distinction is sometimes made by some authors, and perhaps was actually observed in their ancient modes of worship. The altar properly called *ara*, was not elevated above the surface of the ground, and it was devoted to the service of the terrestrial gods; the altars dedicated to the celestial gods were raised to some height, and were thus denominated *altaria* from *alta* and *ara*, or *high altar*; but holes were dug into the earth, called *scrobiculi*, when altars were set apart for the worship of the infernal gods. Altars were adorned with sculpture, representing the figure of the deity to whom they were erected, or some appropriate symbols. A Bacchanal, with a thyrsus in his hand, is the characteristic of the altar of Bacchus; and the figure of Neptune, with the pallium on his shoulder, a trident in his left hand and a dolphin in his right, or a genius with an oar on his neck, clearly indicates the altar which is thus decorated to belong to the sea god. Groves, highways, the tops of mountains, and other conspicuous places, were chosen for the erection of altars.

The altars of *incense*, of *burnt-offerings*, and of *shew-bread*, which were the principal altars among the Jews, were made of shittim-wood; the first and the last were covered with plates of gold, and the second for the burnt-offerings was covered with brass. The Jewish, as well as the heathen altars, afforded an asylum, or place of refuge to such as fled from violence, and even to such as were guilty of crimes, from a notion probably that they were under the protection of the deity to whom the place was dedicated. A similar privilege, it is well known, has been extended in some ages to Christian churches. Solemn transactions, as the administration of oaths, alliances entered into between different nations and individuals, and the confirmation of treaties of peace, have been often ratified and concluded at altars.

ALTDORF, or ALTORF, the capital of the canton of Uri in Switzerland; a fine town, which stands near the lake of the Four Cantons, in a plain surrounded with lofty mountains clothed with wood; contains a population of 4000; is famous as the birth-place of the celebrated William Tell, the intrepid champion of Swiss liberty; and is 20 miles S. E. from Lucerne, and 33 miles S. from Zurich.

ALTENA, see ALTONA.

ALTHEA, Marshmallows, a genus of plants belong to the Monadelphia class.

ALTIN, or ALTYN, a lake of Siberia, which is situated on the elevated country on the north side of the Altaian mountains; is estimated at 90 miles in length and 30 in breadth; the southern extremity never freezes, but the northern division admits of travelling on foot across it in the winter; it is subject to inundations in summer from the melting of the snows, and it is one of the sources of the great river Oby.

ALTITUDE, or Height, is an astronomical term applied to the heavenly bodies, and expressive of their position above the horizon, as the altitude of the sun, of the moon, or of a star.

ALTONA, a city of Holstein, belonging to Denmark, is situated on the north bank of the Elbe, and is the sea-port of the Danish East India Company; is of some commercial importance; has the conveniency of docks for ship-building; and many of the inhabitants, which amount to 25,000, are actively employed in various manufactures. Altona is two miles west from Hamburgh.

ALUM, an earthy triple salt, composed of sulphuric acid, alumina, or pure clay, and an alkali, usually potash, or a compound of sulphate of alumina and sulphate of potash. For its chemical properties, see CHEMISTRY; and for an account of the manufacture of alum, see SALTS, under which will be detailed the history and processes for the preparation of the various saline substances employed in the arts.

ALYSSUM, Madwort, a genus of plants belonging to the Tetradynamia class, some of the species of which were supposed to have the property of curing madness.

AMADAN, or HAMADAN, one of the chief towns of a province of Persia, is finely situated on a spot between Taurus and Ispahan, and on the road from Mecca to the northern parts of Asia. The numerous springs in the vicinity, and the surrounding gardens, add greatly to the beauty of the place, the air of which is so salubrious as to render it the frequent resort of invalids in the spring; and from being occasionally the summer retirement of the Persian monarchs, it has obtained the designation of *royal city*. Among many splendid tombs which decorate Amadan, the mausoleum or tomb of the celebrated Arabian physician, Avicenna, still exists; and, according to a tradition of the Jews, the ashes of Esther and Mordecai repose in a tomb not far from their synagogue in this place, to which, it is said, devotees of that persuasion, from the country about the Levant, sometimes perform pilgrimage. Amadan, it has been supposed, is the ancient Ecbatana, was destroyed by Nebuchadnezer, and rebuilt by Darius. N. Lat. 35° 15′. E. Long. 48°.

AMAK, an island to the south of Copenhagen, about two miles in length and one mile in breadth, and containing about 3000 or 4000 inhabitants, in different villages, who are the descendants of a Dutch colony established in the beginning of the 16th century by a Danish queen, for the purpose of supplying Copenhagen with vegetables, butter, and cheese. The communication between the island and Copenhagen is facilitated by a draw-bridge. The whole island is under excellent cultivation, and is laid out in pastures and gardens. The inhabitants retain their original dress and manners; but intermarriage, and constant intercourse with the Danes, have corrupted their language, which is now a mixture of Danish and Low Dutch.

AMALEKITES, a powerful people of Arabia Petræa, are supposed by some to be the descendants of Amalek, the son of Eliphaz, and the grandson of Esau; but, according to the Arabian tradition, their descent is to be traced to Amalek, a grandson of Noah, and there were different tribes of the same

Amalfi.

name. The progress of the Israelites from Egypt to the promised land was greatly harassed by a warlike tribe of this people, in consequence, it is said, of an enmity still existing in remembrance of their progenitor, Esau, being deprived of his birth-right, and of his father's blessing, by the patriarch Jacob. They were attacked and completely routed by the Israelites under their leader Joshua. The same people, or a tribe under the same name, in conjunction with the Moabites and Midianites, renewed their hostile operations against the Jews in the time of the Judges; but their attacks were vigorously repelled by Gideon. Saul advanced to the capital of the Amalekites, and put the whole people to the sword; at a future period, a few scattered bands of the Amalekites who had escaped, pillaged Ziklag, which was the residence of the family of David, who pursued them, dispersed the plunderers, and recovered the booty; and from this time history is silent concerning them.

AMALFI, a sea-port town in Italy, is situated on the gulf of Salerno, is about 30 miles south from Naples, and dates its origin about the middle of the 4th century, when some families from Rome, proposing to emigrate to Constantinople, were driven by a storm to the shores of Salerno, and settled on the spot. The situation which chance fixed for their residence afforded peculiar advantages for commercial enterprise; and as the inhabitants increased in number and opulence, they were not inattentive to avail themselves of the facilities which it offered for carrying on a lucrative trade with the eastern parts of the world, with the productions and manufactures of which they supplied the countries to the west. About the middle of the ninth century, Amalfi rose to great splendour; assumed the form of a commonwealth; acquired the dignity of an archiepiscopal city; and, for its zealous exertions against the infidels, was distinguished by the title of *Defender of the Faith*. The population of the city was not less than 50,000; the whole trade of the Levant was under their management, and they had establishments in almost every country of the civilized world. The fortunate discovery of the mariners' compass has been ascribed to them, or to the native of a neighbouring village. To add to the dignity and importance of this enterprising people, an order of knighthood was established under the patronage of St John of Jerusalem. The members of this order became afterwards the knights of Rhodes, who were at last absorbed in the celebrated military order of the knights of Malta.

The prosperity of this small but rich commonwealth excited the jealousy of their poorer and more barbarous neighbours; and having repelled repeated attacks, they were entirely overwhelmed by the Normans, after having enjoyed their republican constitution and commercial rank for 300 years. From this time the wealth and power of Amalfi declined, and its lucrative trade was transferred to the Genoese and Venetians. The ruins of a cathedral, and of the splendid mansions of its ancient merchants, are the only traces of the former grandeur of Amalfi, and the diminished number of its inhabitants, now reduced to 4000, presents a sad contrast to the crowded population in the prosperous periods of its history; and its maritime concerns, once so important and extensive, have dwindled into the excursions of fishermen, who are chiefly distinguished for their poverty.

Amalgam || Amazonia.

AMALGAM is a compound of quicksilver and some other metal, varying in its nature and properties according to the metal with which the combination is formed, and the proportions of the quicksilver employed. When other metals are combined, the word alloy is applied to the compound obtained.

AMARANTHUS, or Flower-gentle, a genus of plants belonging to the Monoecia class.

AMARYLLIS, Lily Asphodel, a genus of plants belonging to the Hexandria class.

AMASIA, a large and populous town, the capital of a district of the same name in Natolia, in Asiatic Turkey, was the residence of the ancient kings of Cappadocia, and is worthy of notice as the birthplace of Strabo, the celebrated geographer. Amasia is placed among rugged mountains, and on the banks of a river which discharges its waters into the Black sea; some remains of its former magnificence still exist, and it is the residence of a governor, and of the eldest son of the Grand Signior, the expectant heir of the Ottoman throne. The bulk of the inhabitants are Christians, so that a single mosque only appears in Amasia. The province of Amasia abounds with fine fruits, and furnishes excellent wines. N. Lat. 40° 44′. E. Long. 36° 10′.

AMAUROSIS, or GUTTA SERENA, a disease of the eye, which is supposed to be some affection of the optic nerve. In this disease no external symptoms appear, excepting the insensibility of the eye to the action of light.

AMAZONIA, an extensive region of South America, is about 1400 miles in length and 900 in breadth, stretching from the equator to the 20th degree of south latitude, and bounded on the west by Peru, and by Brazil and the Atlantic ocean on the east. This country was discovered about the middle of the 16th century, by Francisco Orellana, who had accompanied Pizarro in his expedition to those parts of South America which lie to the eastward of the Andes. But he deserted his commander, and, with a vessel manned with 50 soldiers, reached the ocean after a perilous voyage of seven months. When he arrived in Spain the exaggerated account of his adventures astonished all Europe; and, among other marvellous parts of his narrative, he pretended that he had discovered nations so rich that the roofs of their houses were covered with pure gold, and a republic of women, who resembled in their manners the fabulous Amazons of antiquity; and hence the country which he had traversed, derived its name, and the river formerly called the Maragnon was converted into the river of the Amazons.

Amazonia, except near the banks of the river, is scarcely known to Europeans. Every attempt of the Spaniards to colonize it failed. The Portuguese have a few small settlements near the mouth of the river; but the native tribes, which are numerous, and in a state of original barbarity, remain in undisturbed possession of this wide region. The greater part of the country is flat, and during the rainy season, when the rivers are swelled, the redundant waters form lakes and morasses. All the tropical productions are abundant; but the climate, although the temperature be not excessive, is generally unhealthy.

AMAZONS RIVER, originally called the Maragnon, and now the Amazons, presents the most remarkable feature of the extensive region which it traverses, and indeed of the New World. It is distinguished by its magnitude, the length of its course, the number of its tributary streams, and the huge body of waters which it rolls to the ocean. Issuing from the lake Lauricocha, which is about 90 miles from Lima, it proceeds southward, and being joined by many rivers, some of which have flowed 500 or 600 miles, and are equal to the Danube or Nile, it turns to the eastward, and, after a winding course of between three and 4000 miles, falls into the Atlantic ocean, nearly under the equator. At its mouth, it is 150 miles broad; and the depth of the stream, at the distance of 1500 miles from the sea, is not less than 240 feet. The tides are perceptible 600 miles from its mouth, and the descent, in a course of 1860 miles, as it was observed by M. De la Condamine, who sailed down the river in 1743, is not more than 1020 feet, or 6⅗ feet in the mile.

AMAZONS, a fabulous nation of females, who are said to have possessed that part of Asia Minor which lies on the coasts of the Black sea, and from whose society all men were excluded. They were celebrated for their warlike exploits; and, to fit them for martial exercises, they subjected themselves to those laborious duties which usually fall to the lot of men; and to admit the free use of the bow and the javelin, they cut off the right breast, and hence the name, which signifies *without the breast*, according to the Greek etymology, is derived. The existence of such a nation seems to be seriously believed by many ancient historians; and even as late as the 17th century, learned disquisitions are not wanting to prove the same fact. Dr Bryant, in his elaborate investigation of ancient mythology, considers the nation described under the name of Amazons, to have been Cuthite colonies from Egypt and Syria, who established themselves in different regions, and thinks that the name is derived from the word *zon*, "sun," which was the object of their worship. This seems to be a more probable account of the Amazons than the current relations of historians, which, indeed, contain sufficient internal evidence to disprove the whole story.

AMBARVALIA, from the word signifying to *go round*, and *field*, was a festival of the ancient Romans, in which sacrifices were performed to Ceres, to obtain an abundant harvest. It was held in April and July, and was celebrated either by the master of a family privately, or as a public solemnity, in which latter case the priests appointed to this service officiated, and were attended by the people, crowned with oak leaves, and singing hymns to the goddess whose favour was invoked. A bull, a sow, and a sheep were conducted in solemn procession round the ploughed fields, and these victims were afterwards sacrificed on appropriate altars. This festival was also called *suovetaurilia*.

AMBASSADOR, a public minister sent from one sovereign power as his representative at the court of another. Ambassadors are either *ordinary*, or such as reside constantly at the court to which they are appointed; or *extraordinary*, or such as are dispatched on some special mission of importance, and when this is accomplished their powers cease. By the mutual understanding among nations who are in the relation of peace and amity with each other, or, according to the indefinite obligation of the law of nations, ambassadors enjoy peculiar privileges, among which may be mentioned freedom from arrest of their persons, and from attachment of their goods, and the same privilege is extended to the persons and goods of all those who are in their train. But for criminal acts, which fall under the denomination of treason or felony, they are subject to punishment as private aliens.

AMBER, a mineral substance, generally of a yellowish colour, and semi-transparent, is ranked among the *inflammables* in the classification of minerals. Amber is distinguished by the peculiar acid which it affords, and it is not less remarkable for its electric properties. It was the first substance in which those properties were observed, and hence the Greek word *electron*, signifying "amber," is the origin of the name *electricity*. See MINERALOGY.

AMBERGRIS, or GREY AMBER, is an ash-coloured and variegated inflammable substance, which gives out, when melted, a peculiar fragrant odour, for which it is highly valued, and extensively employed in all kinds of perfumery. The origin of ambergris was long uncertain; but it is now distinctly proved to be an animal production; for although it is found floating in different parts of the ocean, it has been frequently extracted from the intestines of a particular species of whale; and therefore the conclusion is sufficiently obvious, that it is a matter secreted by that animal, and is to be considered either as the cause or consequence of disease, since the whales which afforded the greatest quantity were observed to be in a lean and sickly state.

AMBIDEXTER, from the Latin words, signifying "both," and "right hand," is applied to a person who uses both hands with the same facility. By the law of the ancient Scythians, that warlike people were compelled to accustom themselves to the use of both hands alike; and Plato, in the regulations of his republic, recommends the same practice; the purpose of which, no doubt, is, in both cases, to render them more prompt and expert in martial exploits. The Grecian pikemen and the Roman gladiators were trained to the same exercise; and it is recorded in Scripture, that 700 men of the tribe of Gad were capable of fighting equally well with both hands. The superior facility of action, which is most generally possessed by the right hand, has been the subject of physiological investigation, and has been ascribed to a larger flow of blood to that arm; but whatever difference may be observed in the structure of the right and left hands, it seems probable that it depends more on the power of habit than on any other cause.

AMBOYNA, an island in the East Indies, includ-

Ambrose ‖ Ambrosia.

ed under the Molucca or Spice Islands. See Spice Islands for a connected account of the whole group.

AMBROSE, Isaac, a presbyterian clergyman, eminent for his learning and piety, was born about the year 1591; received a liberal education at Oxford; was appointed minister of a congregation at Preston, and afterwards removed to Garstang, in Lancashire, from which he was ejected in 1662 for non-conformity. He is represented by his biographers as "a man of substantial worth, eminent piety, and exemplary life." It was his usual practice to spend a month every year in a small hut in a sequestered spot in the middle of a wood, and, avoiding all intercourse with mankind, to devote himself entirely during the period of his retirement to spiritual contemplation. He died in 1664, at the age of 73. He was the author of "The First, Middle, and Last Things, viz. Regeneration, Sanctification, and Meditations on Life, Death, Judgment," &c. "Looking unto Jesus," and other works, some of which still retain a considerable share of popularity.

AMBROSE was the name of a deacon in the Christian church, who was converted by Origen, and flourished about the beginning of the third century. He was a person of wealth and high rank, and is said to have employed his influence and riches in promoting the study of sacred literature.

AMBROSE, St. who lived towards the end of the fourth century, was at first governor, and afterwards bishop of Milan, and was greatly distinguished by the sublimity of his sentiments and the eloquence of his language.

AMBROSIA, according to the Heathen mythology is the solid food of the gods, whose drink was called *nectar*. Ambrosia, which is derived from the Greek, and signifies something which is not mortal, was supposed to confer immortality on those who were admitted to the felicity of enjoying it.

Ambrosina ‖ Amercement

AMBROSIA, a genus of plants belonging to the Monoecia class.

AMBROSINA, a genus of plants belonging to the Gynandria class.

AMBROSIUS, Aurelianus, a celebrated general of the ancient Britons, was descended from a Roman family, and flourished in the latter part of the fifth and beginning of the sixth century. He was successful against the Saxons, and compelled them to retire from the western districts of Britain. Having assumed the sovereign power, he directed his attention to the internal arrangement of the affairs of the kingdom, ordered the churches to be repaired, and the public worship to be restored. The building of Stonehenge near Salisbury, a singular monument of mechanical power, which has long baffled the researches of the antiquary, is ascribed to Ambrosius; but in its erection, it is said, he was assisted by giants and magicians.

AMELLUS, Starwort, a genus of plants belonging to the Syngenesia class.

AMEND, or Amende, according to the practice of the French courts, is a pecuniary fine imposed by a judge for any crime, false prosecution, or groundless appeal.

AMENDE HONORABLE, a species of punishment formerly inflicted in France on traitors or parricides, when the offender was delivered into the hands of the executioner, his shirt was stripped off, a rope was put round his neck, and a taper in his hand, he was then led into court and required to beg pardon of God, the King, the court, and the country. The same term is also applied to a public recantation of an injury, made in court, and in presence of the person injured.

AMERCEMENT, or Amerciament, is a term in English law, and signifies a pecuniary fine imposed on offenders at the pleasure of the court, and without being regulated by any express statute.

AMERICA.

America.

America is the name of a large continent situate in the western hemisphere, from which circumstance it is sometimes called the Western Continent, and not unfrequently the *New World*, as having been but recently made known to the inhabitants of other parts of the globe. It is of immense extent, reaching from about the 54th degree of south latitude to a very high but hitherto unascertained northern latitude, and lying between the 35th and 136th degrees of longitude west from Greenwich. It is above 9000 English miles long, varying in breadth from 60 to 4000 miles. Equal to nearly one-third of the habitable earth, this great surface necessarily presents many differences of feature, as might be expected from the different climates through which it extends; but these diversities, it has been remarked, concur in one general expression of dissimilarity to any of the longer known continents. America is said to surpass them, for example, in the elevation and magnitude of its mountains, though some facts respecting Asia, lately discovered, make this particular doubtful; in the profusion and copiousness of its rivers, and the number and amplitude of its lakes; while its atmosphere scarcely recognizes those laws for the distribution of heat which are generally observed in other regions; and certain peculiarities in its animal and vegetable productions testify the independence and resources of that wisdom by which the common empire of nature is sustained. The usual division of this continent into North and South America, is pointed out by the striking circumstance of a connecting neck of land, about 1500 miles long, and narrower in some places than the isthmus which unites Africa with Asia, and by a diversity in the manners and language of the primitive inhabitants.

I. South America.

Like the opposite continent of Africa, South America is entirely surrounded by water, with the exception of a narrow point of land, which scarcely prevents the junction of two contiguous seas. Its extreme length,

South America.

which may be reckoned from Cape Vela, in about 12° north lat. to Cape Horn, in the island of Terra del Fuego, in 55° 58′ of south latitude, includes a distance of nearly 4000 geographical miles; and its greatest breadth, which seems to lie in the parallel of 5° south, is about 2880 miles. Some of its natural features merit particular notice.

Mountains.—The mountains of South America are extremely lofty, and of so great an extent as in some regions to form pretty considerable provinces. Thus, the Andes, a magnificent ridge, springing up near the southern extremity, and following the direction of the western coast, till it approach the Gulf of Darien in the north, afford space sufficient for the establishment of kingdoms, reckoning by the standard of European policy. It is in a summit of this ridge, called Chimborazo, near to the equator, that we find the astonishing elevation of 20,280 feet above the level of the sea, being 5000 feet higher than Mont Blanc in Switzerland, but much lower, it has lately been said, than a ridge in Asia. The plain of Quito itself, from which this summit rises, is higher than the top of the Pyrenees. About 25 miles to the S. E. of Quito is Cotopaxi, a volcanic mountain, upwards of 18,000 feet in height, reckoned in the same manner; and throughout this equatorial region are other summits of very extraordinary, though inferior elevation, as Cayamburo, Pinchincha, Sangay, the Altar, &c. The Andes branch out in various directions, and pervade a great part of this continent; but much of the interior, hitherto indeed but little explored, is conceived to form plains of an extent little less remarkable than the mountains with which they exhibit so important a contrast.

Rivers.—The magnitude of the rivers is in proportion to the grandeur of the mountains whence they issue. It is enough to mention the Maragnon, or river of the Amazons, the La Plata, and the Oronoco, some of the tributary streams of any of which would be reckoned immense in our part of the world. The natural history of these rivers is still very imperfect, and, judging from their size, complicated courses, and the number of their branches, will probably long remain so.

The general direction of the Maragnon, certainly the largest river in the world, is from west to east, between the equator and the 5th degree of south latitude, and the length of its course has been estimated at 3300 miles, including its windings. This is not so great a length, it is conjectured, as that of the Kian Ku, a river in China; but then in breadth and volume of water there is an astonishing superiority on the part of the former. The effect of the tides is said to be perceptible 600 miles from the mouth of the Maragnon. We may have some conception of the size of the river La Plata by this circumstance, that its banks are not discoverable from a vessel in the middle of its stream where it enters the ocean. But its depth is not proportioned to this width, although navigable above 1000 miles inland. The Oronoco is a very rapid and tortuous river, which often overflows its banks, and in consequence is liable to have its course much altered. It is to the north of the Maragnon, with some of the navigable branches of which it appears to be occasionally if not permanently connected. There can be little or no doubt, indeed, that, comparatively, a small degree of labour, properly bestowed, would effect a junction between most of the important subsidiary rivers in this region, and so render commercial intercourse more extensive than in any other country of the world. For this purpose, an adequate outlet, on the western coast, in subserviency to the chief branches of the Maragnon, is the only thing wanting.

Lakes.—As far as is yet known, South America has no lakes which are worthy of being compared with those found in the northern division. That of Parima, in the north-east quarter, has been described as 100 miles long and 50 broad. But the accounts respecting it are not much entitled to credit. It is supposed to give rise to several considerable rivers, and also to receive the chief stream of the Oronoco. Titicaca, which is near the middle of the western coast, and 100 miles from the ocean, is the most important lake in South America, and is about 240 miles in circumference, with a depth of water from 70 to 80 fathoms. In attempting to establish a communication with the Pacific ocean, so as to perfect inland navigation, this lake seems to offer advantages of the highest consequence.

Natural History.—The mineralogy of South America is exceedingly varied. All the classes of rocks, primitive as well as secondary, with their subordinate orders, exist in this extensive region. Volcanic products, besides, are scattered in great profusion, and most of the metals are found in abundance. On this part of South American natural history, the labours of Humboldt, a Prussian traveller, have lately contributed much curious information. A country occupying so many degrees of latitude, must present great differences of climate and seasons. In the extreme south, though by no means a very high latitude, there is almost perpetual winter. The seasons gradually become milder in approaching towards the north; and even under the equator, the heat, unless in some peculiarly confined situations, can scarcely be called excessive. In general, a difference may be allowed of about 20° degrees of latitude between this continent and the Old World, to admit corresponding degrees of temperature. Cold predominates in the New World, depending, no doubt, on the superior elevation of the land. Rain is frequent, and may be said to constitute the winter of some American countries, as dry weather does their summer. The seasons, of course, are the reverse of those which take place in the northern hemisphere.

1. Terra Magellanica, and Patagonia, are the names applied, with little propriety, perhaps, to that portion of this continent which reaches from the strait denominated after Magellan, a Portuguese navigator, who discovered it in 1519, to a line supposed to be drawn in the latitude of 45° south from the Pacific to the Atlantic ocean. It has been little frequented, and, excepting the coast, to which the attention of navigators has been often directed, is very imperfectly known. There are few temptations, indeed, to bring visitors to this region. Far removed from the theatre of commercial interests, and the arts which dignify social life, this inclement

South America.

country must probably long remain in the possession of its barbarous, but not inhospitable inhabitants, and present a mortifying picture to the benevolent philosopher. He will console himself, however, in the persuasion, which almost every one who has been personally acquainted with them, encourages, that contentment, the offspring of ignorance and insensibility, lessens the miseries of these wretched beings. But this consolation, unfortunately, must be somewhat modified by the fact, that an intercourse with the Spaniards towards the north, has subjected them to some of the evils of civilization, without its corresponding benefits.

Of all the tribes which are thinly scattered throughout this country, and denominated Moluches, Tehuels, Puelches, and Aucas, these last are conceived to be the most improved. They are said to have made some progress in agriculture, and to be able to manufacture garments of wool and cotton. The others, in general, subsist chiefly on animals taken in the chace, to which, also, they are indebted for their only coverings from the rigours of the climate.

The gigantic size of some of the people found in this region, has been so frequently and so respectably affirmed, that it is hazardous to attempt its denial. Some exaggeration, no doubt, may have occasionally taken place; but it may be confidently stated, that a stature which would be thought extraordinary in Europe, is not uncommon among the Patagonians.

The people of Patagonia are either altogether without religion, or are addicted to the worship of the sun and moon as the supreme sources of the scanty favours which they enjoy.

Horses, of which the Patagonians are expert riders, are rather plentiful amongst them since their intercourse with the Spaniards. They have also some sheep and cattle. Among the wild animals of this region, are the guanaco and armadillo.

In many respects, the island of Terra del Fuego, that is, Fiery Island, so named by Magellan, who observed volcanoes in its mountains, bears considerable resemblance to the land now spoken of. It lies to the south of the strait formerly mentioned, is of great extent, and, with several other islands in its neighbourhood, has been often visited by vessels destined for the South Pacific ocean. But it does not afford any circumstance of sufficient interest to occupy attention in this place.

2. Chili—denotes a country extending northwards above 1000 miles along the western coast, from the 45° S. Lat., and having a breadth varying from 300 to 500 miles. The name is that used by the natives, and is said by them to signify a bird whose appearance is reckoned auspicious.

This is a delightful region, possessing a temperate climate and a productive soil. The existence of several volcanoes in the mountains of the Andes, by which it is traversed, and the sparing occurrence of slight earthquakes, cannot materially lower the estimate we form of its advantages. It is singular, then, that a great part of this country should still remain unoccupied, either by native tribes or the Spaniards, the latter of whom have settled chiefly towards the sea-coast, on which they have built several towns; and the Araucans, by much the most important of the former, inhabit a fine tract, reaching from the river Valdivia to the river Biobio, bounded on the west by the ocean and on the east by the mountains already named. This people exhibit several noble qualities, which need only the fostering care of a liberal and judicious government to produce an excellent national character. But this benefit, even supposing the Spaniards capable of yielding it, would probably be resisted by a spirit of pride in themselves, which disdains alike to acknowledge an imperfection, and to be indebted to another for its removal.

South America.

That part of Chili which is inhabited by the Spaniards is divided into 18 districts, governed by a single chief, who has almost unlimited power in all the concerns of the province. The population may be estimated at upwards of 300,000, of which more than two-thirds are either negroes or a mixed race.

Trade.—Commerce has hitherto made small advancements in this country. The chief articles of barter are the precious metals, (by no means wrought to the full extent,) hides and leather, grain of different kinds, and fruits. The principal trade carried on is with the natives of the adjoining provinces. A communication with the East Indies, properly managed, would render Chili one of the most prosperous countries in the world.

Natural History.—The botany of Chili is exceedingly rich. Almost all the choicest European plants thrive in it, and it abounds in others, of which we know but the names, or possess merely specimens. Thirty-six species of quadrupeds have been enumerated by Molina, who has so well treated of this province. Eagles, vultures, and condors enjoy the heights and precipices of the Andes, and in the lower region are found great varieties of smaller birds.

3. Peru.—Stretching northwards from Chili, along the western coast, lies the Spanish province of Peru, in former times a powerful empire under a native prince. Great diversity of climate prevails in this region, but the heat is much more moderate than might be expected from the position with respect to the equator; and in the mountainous districts towards the east, a great degree of cold is experienced. Rain is seldom known in the lower parts of the country, where a plentiful dew, which falls during the night, supplies its place to the vegetable kingdom. Tempests, hurricanes, thunder and lightning, are nearly as rare; but earthquakes are often felt, and there is reason to fear that their destructive operation is constantly increasing.

Natural History.—There are immense forests spread over this province, indicating scantiness of population. The soil, however, is, in general productive, affording a profusion of fruits and flowers, and, in some districts, yielding a tree whose bark has been long celebrated as a restorative and tonic medicine.

Among the animals which swarm in this region, are mentioned the jaguar, tapir, cougar, a species of deer, the mountain cat, a sort of fox, and bears of a very fierce nature. Nor is the feathered tribe less diversified or interesting.

Before the annexation of Potosi and some other districts, formerly a part of Peru, to the vice-royalty of La Plata, the mineralogy of this province was perhaps the most copious, in point of the precious metals, in South America. But there remains enough in Lima, still attached to it, to render it of very high importance to the Spanish government. The mines of Lauricocha are said to have been discovered as far back as the beginning of the 17th century, by the accidental melting of silver, occasioned by a shepherd having kindled a fire for some common purpose. The mine of Guancavelica, which had supplied such immense quantities of quicksilver for about two centuries, is understood to be exhausted. Another was lately opened in the district of Huamalies, promising a rich supply. The gold and silver mines of Peru, together, are conjectured, on pretty good grounds, to have yielded about L.8,000,000 Sterling, in 10 years preceding 1790. Quito, which formerly belonged to Peru, was disjoined from it in 1718, in favour of New Granada.

The provinces, or intendancies as they are denominated, now included in Peru, are as follows:

Lima, whose city of the same name, situate about six miles from the sea, on the south of the river Rimac, in 12° south lat. is the capital of Peru; the city, which was founded in 1525, is computed to contain 64,000 inhabitants, is built of wood, but displays some very elegant edifices, and few places in the world have been so often visited and nearly ruined by earthquakes; *Truxillo*, north of Lima, having a capital of the same name, founded by Pizarro, a character well known in American history; *Tarma*, to the north-east of Lima, a district much inhabited by Indians; *Guamanga*, eastward of Lima, noted for its gold mines, and its capital of the same name was also founded by Pizarro; *Cuzco*, an inland district to the south-east of Lima; its chief city, Cuzco, which was originally the residence of the native kings when the Spaniards invaded this country, scarcely contains 16,000 inhabitants, the majority of which are Indians; *Arequipa*, a maritime district, to the south of Lima, fruitful in grain, and possessing a very mild climate; *Guantajaya*, north and west of Guamanga, formerly noted for silver mines, which are now abandoned; *Guancavelica*, between Guamanga and Lima, a hilly country, neither very fertile nor very agreeable; and the silver mines of this district have become almost useless from frequent inundations of water.

The population of Peru, as now constituted, perhaps does not much exceed 1,000,000, and in all likelihood is on the decline.

4. La Plata—is an immense region, made up of several provinces formerly reckoned distinct, and since 1778 erected into a vice-royalty, in which the chief dignity and power of Spanish South America may be said to consist. It is conceived to be bounded on the south by the province first described; on the west by Chili and part of Peru, from both of which it is separated by one of the ridges of the Andes; on the north by the parallel of 14° S. Lat.; on the east by the South Atlantic ocean and part of Brazil. On the southern extremity it is somewhat contracted by the ocean, where it is penetrated by the mighty waters of the river from which this province derives its name. Its length may be stated 1500 miles, and its breadth from 600 to 800. Beside part of ancient Peru, this vice-royalty includes the provinces of Buenos Ayres, Paraguay, Tucuman, Chaco, Los Moxos, Cuyo, &c.

Buenos Ayres is a vast plain, pervaded by the river La Plata, or the huge streams which form it, where they approach to mingle their waters before rushing into the ocean. The soil is in general rich, producing great varieties of grain, &c. and abounding in choice pastures, the abode of immense herds of cattle of the buffalo kind, wild horses, deer, &c. The purity of the climate is implied in the name of this province and of its capital, which is the residence of the viceroy and the seat of government. It is a fortified town, on the right bank of the river, but without any proper harbour, and carries on a respectable trade with many European ports. Its chief exports are hides of different kinds in the raw state.

Paraguay lies between a river of that name and the Parana, the great north and eastern tributary streams of the La Plata. It is rather a moist country, and very woody. Assumption, the capital, about 50 leagues higher up than the junction of the two rivers now mentioned, is but a small and rather ill-built town, pleasantly situate however, and having delightful gardens in its vicinity. The northern parts of this province are not much known. Altogether, perhaps, Paraguay has been neglected, in consequence, it is probable, of its being deficient in the precious metals, the original and strongest allurement on the minds of its European masters.

Tucuman, now divided into Salta and Cordova, lies between 23° and 33° S. Lat. and 61° and 68° W. Long. entirely inland. It is possessed of a mild climate and a fertile soil, and is withal well watered by several streams which run toward the river Parana. Few of its towns are large, and the whole province is reckoned to contain not much more than 100,000 inhabitants. Most of these, however, enjoy great affluence; in proof of which, it is mentioned by one Spanish writer, Estalla, that there is no person in it so poor as not to kill a heifer every day for the use of his family.

Cuyo, which is towards the west and south-west of Cordova, among the mountains of the Andes, has some vallies extremely fertile in fruits, and is noted for its wines. It is now considered as annexed to Cordova.

The country of the *Pampas*, to the south of Cuyo and Buenos Ayres, is very flat, and has scarcely any other inhabitants than some tribes of wandering savages, who can hardly be said to own the sovereignty of the Spanish nation. To the north of Tucuman are the provinces of *Chaco* and the *Chiquitos;* and north-west from the latter, *Los Moxos*. Of these we have but imperfect information; some native tribes still retaining chief possession, and admitting but little intercourse with the Spaniards. Indeed, it may be pretty confidently affirmed, that not more than one-half of the vice-royalty of La Plata has been examined by the nation to whom it forms so vital an object of policy. But the judicious counsels which effected the erection of this vice-royalty, so as to give it a preponderance over Peru, would perhaps have accomplished a survey of the districts composing it, if the affairs of the mother-country had been propitious to this distant interest. The frequency of land journeys between Buenos Ayres and the rich city of Potosi, which are in consequence now substituted for the tedious maritime expedition round Cape Horn, will, in time, it is likely, be imitated in other directions, and at last secure a profitable acquaintance between the various districts of this most important region. Certain recent events affecting the state of its dependence on Spain, may contribute to the celerity of so desirable an operation. It is probable, that a liberal constitution of government, and some abatement of the exorbitant influence of the clergy in this portion of South America, might materially modify the condition of the whole commercial world. To the chief cities of this vice-royalty, already mentioned, Buenos Ayres, the capital, Potosi, supposed to have 100,000 inhabitants, &c. we may add the following: Monte Video, on the north side of the river La Plata, at its mouth, noted for the best harbour in the province to which it belongs, and said to have 15,000 inhabitants; Cordova, in the district of the same name, a wealthy, handsome, and improving town; La Paz, north of Potosi, and capital of a province so called, a well-built, thriving place, with a population of 20,000 souls; Salta, in Tucuman, celebrated for an annual fair, at which, it is said, 4000 horses and 60,000 mules have been known to be assembled. The consumpt of these latter animals in the mountains of Peru, where they are chiefly taken, is astonishing. They are employed in carrying burdens from the mines, and in travelling. The town of Assumption, formerly mentioned, was at one time superior in extent and consequence to Buenos Ayres.

Natural History.—A naturalist would be amply rewarded for his labours in this region. In mineralogy, the objects are various and abundant. To botany its contributions are liberal, though the hand of science has hitherto been but sparingly occupied in their arrangement. Here are found the sarsaparilla, the sassafras, the guaiacum tree, that which yields the elastic gum, commonly called Indian rubber, the cinchona, or jesuits' bark-tree, the nux vomica tree, great varieties of palm, fruit-trees in immense profusion, and of the richest kinds, particularly pomegranates, pine-apples, oranges, figs, peaches, &c. Of the animal kingdom, so copious in La Plata, we may notice the elk, ant-bear, jaguar, or American tiger, a species of hippopotamus differing from that found in the Old World, several kinds of large and small serpents, the ostrich and condor. The people, in general, throughout this vice-royalty, computed at 1,000,000 Spaniards or Creoles, and a comparatively small number of natives, are described as enjoying supreme earthly advantages. The former are, on the whole, well educated, courteous, handsome, and attached to pleasure. Since the complete establishment of their power, it is probable that the latter have been treated with kindness, which could not fail to conciliate, if the recollection of past events were friendly to attachment.

5. Brazil.—Hitherto we have treated of provinces, either in part or altogether subject to the Spaniards, and have had occasion to remark the imperfection of the accounts which they have published respecting them. Equal, if not greater jealousy, and certainly a larger share of ignorance, have prevented their neighbours, the Portugueze, from informing the world of the particulars of their possessions in South America. This is the more to be wondered at by an inhabitant of Britain, who cannot but expect some liberality of communication in favour at least of his own nation, which has long been justly considered as the main support and most faithful ally of the parent state. It is undoubtedly a subject of the deepest regret to every enlightened mind, that one of the fairest portions of the universe should have fallen into the hands of a people too stupid to do it justice by their mode of management, and too narrow-hearted to give it the chance of even charitable improvement by an honest display of its real condition.

Of Brazil, to which we now allude, we have the more reason to regret the scantiness, and perhaps inaccuracy of our knowledge, as, from its position in the American continent, it perpetually urges and perpetually mocks our keenest curiosity.

Brazil may be said to be bounded on the south and west by the Spanish provinces last described, on the east by the Atlantic ocean, and on the north partly by the same, and partly by the river Maragnon. The treaty of St Ildefonso, in 1777, between the Spaniards and Portugueze, strictly defined its limits. This region, possessing great variety of soil and climate, has been divided into several provinces.

Rio Janeiro, including *Rio Grande*, extends from Buenos Ayres to the province of Bahia, and is bounded on the east by the sea, and a chain of mountains on the west. It is well watered, has an excellent climate and fertile soil, possesses some rich gold mines, and contains a population of above 100,000 souls. The capital of the same name, or St Sebastian, as it is called, the greatest commercial city in Brazil, is large, elegant, and wealthy, but is very unhealthy, in consequence of the situation being near some extensive forests, which are supposed to occasion too humid an atmosphere.

Bahia, to the north of the preceding province, and stretching along the eastern shore, is reckoned the most populous, if not the most opulent of the Brazilian government. The inland parts are covered with forests; and the towns on the coasts are neither very considerable nor very inviting. Bahia, or St Salvador, the capital, though large, has no pretensions to elegance, and is inhabited by a set of people who are little attentive to cleanliness and improvement. Since the Dutch, an industrious nation, were obliged to abandon this country, there has scarcely one effort been made to arrest or to banish indolence and torpid luxury. The principal people are generally carried about in palanquins by their slaves, of whom the consumpt is so rapid that it is thought almost miraculous when any of them survive seven years.

Pernambuco, the most easterly province of Brazil, is still farther towards the north, and, with the exception of its western or internal side, is almost entirely bounded by the ocean. Some of its extensive plains afford plenty of cotton and sugar. There are several towns and villages on the sea coast, of which

South America.

Olinda is the largest; but the narrowness of its harbour, in addition to circumstances quite congenial to the character of the Portugueze, has prevented it becoming of much importance.

Maragnon and *Para*, two provinces to the north and north-west of Pernambuco, the former of which is partly on the coast, and the latter is washed on its northern limit by the waters of the river Maragnon, though large, afford little to interest the lover of civilization and improvement. Much of the country is uncultivated, and the population is scanty throughout.

With the inland provinces our acquaintance is still more circumscribed. In the mountains of one of them, *Matto Grosso*, there are gold mines; and in those of another, *Minas Geraes*, are found most of the diamonds for which this country has been celebrated.

The natural history of Brazil differs little from that of some of the regions already described.

6. Guiana.—Between the rivers Maragnon and Oronoco, bounded on the east by the Atlantic ocean, and on the west by a line drawn along the river Negro, are situate those provinces classified under the general title of Guiana, and particularized by the names of those European nations which earliest obtained the property of them, as *Portugueze, Dutch*, and *French*. The climate is on the whole temperate, allowing for geographical position, and the soil very variable. Dutch Guiana is most known. It contains the colonies of *Surinam*, *Berbice*, *Demerara*, and *Essequibo*. These are important settlements, and whether in the hands of the British or Dutch are likely to experience very rapid improvements. Coffee, cocoa, sugar, cotton, are the chief exports. French Guiana was taken possession of by the British and Portugueze in 1809. It differs little from the former in point of climate, soil, and productions. A good deal of labour is requisite to render either very healthy, viz. clearing forests, and draining marshes, &c.

The botany of Guiana, in general, is represented as peculiarly interesting, and so must the zoology, if abundance of reptiles can be conceived a strong enticement to its study.

A territory in some maps denominated *New Andalusia*, or *New Cumana*, has of late received the more appropriate title of *Spanish Guiana*. It is to the north of the Portugueze possessions, is bounded on the east by the ocean, on the south by Dutch and French Guiana, extends along the Oronoco, which forms its northern limit, but is somewhat indistinctly defined on the west. Hitherto it has not been much explored; but the researches of Humboldt have proved it to be highly interesting. In this province it is that the junction takes place between the Oronoco and the Maragnon, by the intervention of the Negro. This singular circumstance, which had been noticed in a map of the country as early as 1713, but afterwards frequently denied by those who might be supposed acquainted with the fact, was completely confirmed by the traveller now mentioned. According to him, the navigation is extremely hazardous, and a vast space of country which he traversed throughout in effecting it, was quite destitute of inhabitants. The whole population of Spanish Guiana, indeed, is conjectured to be no more than 34,000, and there are only four towns and three villages in the province.

South America.

7. Caraccas.—This province, which belongs to Spain, lies on the north side of the Oronoco, and is bounded on the east by the gulf of Paria, which divides the island of Trinidad from the continent, the Caribbean sea on the north, and the vice-royalty of New Granada on the west. It comprehends various districts, as *Cumana*, *Caraccas proper*, *Venezuela*, *Maracaibo*, and *Varinas*, which, with the island of *Margarita*, belonging to the same government, are estimated to have a population of upwards of 700,000 souls.

A straggling branch of the eastern Andes, pervading this province, modifies the temperature of the climate, and furnishes a multiplicity of streams and rivulets which fertilize the level countries to the north and south of its range. Nor are the heights themselves incapable of supporting inhabitants. The lake of Maracaibo, a sort of sea or gulf, reckoned upwards of 100 miles long, north and south, and 50 or 60 in breadth, is a singular feature in this country, productive of no trifling benefits. It is navigable for large vessels. The town of the same name, built on the western shore of the lake, is a place of some consequence, containing about 20,000 inhabitants, and carrying on a tolerable trade in cocoa, tobacco, and hides. If the situation were not somewhat unhealthy, and storms and earthquakes were rarer, its prosperity would certainly be more conspicuous.

Caraccas, the capital of the whole province, is a still more flourishing town, and has about double the population. Though built in a valley, its elevation above the sea is more than four hundred fathoms, which may occasion the salubrity and mildness of the atmosphere. The inhabitants are a gay, luxurious, but not inactive race, and are particularly zealous for the doctrines and practices of the Romish Church. This town is often called St Jago de Leon. Cumanas, in the province so named, has upwards of 20,000 inhabitants, most of whom are Creoles.

There are many more towns scattered throughout this country, and an immensity of villages, from which it is warrantable to make an inference in favour of its character. To this spot the attention of Europe has been for some time directed, to witness a contest between an arbitrary, but really imbecile government, and its subjects, just opening their eyes to their true interests, in which it is impossible, at least for a Briton, not to feel his heart and judgment anxiously engaged. An issue, such as he would hope for, might be followed by beneficial consequences to the rest of South America, which it is totally absurd to suppose will ever be the creatures of will and ability on the part of the superannuated authorities.

8. New Granada—is an extensive and highly interesting vice-royalty. Its somewhat singular position will be much more easily ascertained by inspecting a map than from any verbal description. On the north it projects into the Caribbean sea, which is merely a portion of the Atlantic ocean, while its western outline is washed by the great Pacific ocean, and on the south and east its boundaries are constituted by the river Tunguragha, and part of the Mar-

South America.

agnon and Negro. In this extensive space are included various districts.

Quito, which formerly belonged to Peru, now forms a part of New Granada. Much of the country is still unexplored. It extends from the ocean on the west to the Portugueze settlement in Brazil on the east, and from about 2° S. to 2° N. Lat. The features of this country are perhaps the grandest in the world, and the frequency of earthquakes and destructive tempests, by occasioning perpetual changes, gives it a degree of interest which scarcely any other region produces. The soil appears to possess an incessant and inexhaustible fertility, hardly ever requiring the least indulgence of time, as if nature, continually apprehensive that the terrible convulsions to which she is liable, would obstruct her operations, were determined to yield the full amount of her blessings before their occurrence. No sooner, then, is one crop ripened, or one series of fruits brought to maturity, than others succeed with a rapidity and profusion which rather oppress than gratify the inhabitants. These favours, however, though sufficient to tempt a large population, do not counterbalance the precariousness and brevity of human existence. Some varieties of climate are to be met with in this region, dependent on peculiar situation with respect to the sea and the mountains. The city of Quito is large, well built, thriving, and contains about 60,000 inhabitants, Spaniards, Creoles, and Indians. It is situate almost exactly under the equator, on a level plain, 9000 feet above the level of the sea; a circumstance essentially favourable to the temperature of the atmosphere. Like other towns in this region, it has often suffered from the causes already mentioned, and still oftener witnessed with horror the devastation of the towns and villages around it. An earthquake took place in this province on Feb. 4. 1797. Quito itself suffered little in reality; but the people dearly purchased prolonged existence, by a state of apprehension approaching to the highest frenzy, and the view or agonizing tidings of the irremediable calamities which it inflicted. Some places were instantaneously swallowed up by the yawning earth; others were overwhelmed by water; the fall of mountains, shaken from their base, proved a terrific instrument of devastation: and the pestilential vapours arising from the bodies of those whom some such catastrophe had not buried, still more extensively spread this compendious ruin.—Upwards of 35,000 persons are said to have perished.

Guayaquil and *Cuença*, districts to the south of Quito, but once reckoned part of the ancient kingdom of that name, are well accommodated for trade by a large gulf and several bays or creeks, one of which in the former affords the choicest harbour on this coast. The two cities, of the same name with these provinces, are large, and on the whole improving, though not to the amount of their advantages. Guayaquil is celebrated for the beauty of its women. Cuença is surpassed by few towns in respect of local benefits.

Popayan, north of Quito, is almost entirely situate in the Andes, and possesses a temperate climate, considering its latitude. In some of the mountains of this province, as indeed throughout Granada, are mines of gold and precious stones. Popayan, the capital, is a neat little town, enjoying almost perpetual spring, with all the plenty and luxuriance of summer.

South America.

Choco, to the north, and formerly reckoned a part of Popayan, differs little or nothing from it in soil, climate, and productions.

Santa Fe de Bogota, is nearly in the centre of this vice-royalty; and in consequence, more perhaps than of any other circumstance, its city, of the same name, is made the seat of government. This province is hilly, well-watered, and enjoys a mild climate. The capital contains 40,000 inhabitants, is an archbishoprick, can boast of an university, and, besides other advantages, is the residence of some of the most distinguished Spanish families in South America. Of the districts to the east of the Andes, in the direction of the rivers Napo, Parana, (both branches of the Maragnon) Negro, and Oronoco, denominated *Macas*, &c. very little is known.

What remains to be noticed may be conveniently divided into two parts; one comprehending the districts of *Santa Martha*, *Carthagena*, and *Zinu*, in the north; and the other, commonly denominated the isthmus of Darien, or Terra Firma, which is formed by *Choco* already mentioned, *Biruquete* to the west of it along the sea coast, *Darien*, and *Panama*.

Santa Martha is the most eastward of the first part, being separated from Maracaibo, or Venezuela as it is often called, by a branch of the Andes, and bounded on the north by the Gulf of Mexico, having Bogota on the south, and Carthagena, from which it is parted by the river Magdalena, on the west. The mountains are often covered with snow, and the plains are fruitful in grain, &c.; but the population is scanty, and its chief town, of the same name, is rather on the decline. This place was destroyed by Sir Francis Drake in 1585; and the new town often suffered from the buccaneers, who infested this coast.

Carthagena and *Zinu* are much in the same predicament in every respect. Their position along the gulf we have named, at one time so much traversed by Spanish galleons, &c. seems still to invite the efforts of commerce, and some good havens promise security and abundance. But, by a fatality that attaches to almost every thing Spanish, both natural and incidental advantages are either rendered useless by indolence, or are prostituted to a luxurious superstition. Carthagena is a handsome town, with more than 20,000 inhabitants, who have of late become attached to the manners and dress of Europeans, from whom it is to be wished, that they had acquired also a taste for beneficial studies, and a spirit of industry. This place has been often visited by hostile fleets. The river Magdalena is navigable for small vessels to a considerable distance from its mouth, and the towns on its banks are supported by the trade between Quito and the northern districts.

Birquete, a small district on the western coast, as it were skirting Choco, presents nothing of importance to our attention.

North America.

Darien, an unhealthy territory, was once well inhabited, but has declined rapidly in modern times, in favour of wild beasts and reptiles, which swarm in almost primæval security. On the northern shore of this district, near what has been called the gulf of Darien, a body of Scots to the amount of 1200 formed a settlement in the year 1699, which they denominated, in honour of their native country, New Caledonia. It was of short duration; for it was inadequately supported by the parent state, and indeed invidiously regarded by the English East India Company, who had sufficient influence to contribute essentially to its ruin. The recollection of its miseries and hard fortune long operated most injuriously on the state of affection between the sister kingdoms.

Panama, which forms the junction of South and North America, like the other districts now enumerated, has dwindled into comparative insignificance. It was never either very fertile or very salubrious; but a brisk trade, for which it was conveniently placed, gave it importance at one period. The town of Panama, on the west coast, rendered of consequence by its participation in the trade established over land between the gulf of Mexico and the coast of Chili and Peru, had some pretensions to be thought both elegant and wealthy, previous to the decline of commerce, and a fire which took place in 1784. Portobello, on the north coast, has suffered nearly in an equal degree from a similar cause. Its excellent harbour might retard its decay, if the temperature and salubrity of the climate were proportioned to the convenience of its position. The forts which defended it were destroyed by Admiral Vernon in 1739.

II. North America.

North America extends from that part of the isthmus of Darien which we last described, to a degree of north latitude not exactly ascertained, but which certainly exceeds 70°, and is comprehended between the 52° and the 167° of west longitude. Without comprehending Greenland, it may be reckoned at about 5000 miles long, and to have a breadth varying from 60 to upwards of 4000 miles. Its form is singularly irregular, presenting a multiplicity of projections and indentations; and the frequency and vast size of the seas and lakes which pervade it, or are studded on its surface, suggest the notion that it has been but lately and imperfectly recovered from the ocean.

The mountains are not so lofty as those of the southern division, but they are of vast extent. The chief ridges are, one arising from the isthmus which connects the two portions of America, and running with considerable deviations nearly in a north-west direction, and another on the eastern coast, to which it forms nearly a parallel line. The space between these chains may be considered as a vast elevated plain, intersected by rivers, and spotted with lakes, having few eminences, and these merely subordinate to the high ranges by which it is skirted.

Rivers.—The rivers of North America are inferior to those of the southern part, but will bear comparison with those of the Old World. The Mississippi is entitled to the first place. It rises from the eastern side of the mountains on the west of the great inland plain above-mentioned, which it traverses in a south or south-eastern direction, falling into the northern part of the gulf of Mexico, a distance, it has been variously alleged, of from 1400 to nearly 3000 British miles.

North America.

The St Lawrence is the next in importance, and, in breadth of outlet, indeed, is superior. Issuing from lake Ontario, and performing a course of 700 miles, it flows into the North Atlantic ocean, at the gulf or bay which bears its name. Its source ought to be traced to lake Superior, or even lake Winipec, which would vastly increase its nominal consequence. The Ohio, a branch of the Mississippi, and which itself is formed by two considerable rivers, the Alleghany and Monongahela, in addition to several minuter streams, is understood to run a course of more than 1000 miles. The name of the Alleghany is derived from the great ridge of mountains on the eastern coast, whence the river so called has its source. North America is still imperfectly explored, particularly towards the north, and on the western side, where it cannot be doubted that very important discoveries are reserved for the resolution and enterprise of succeeding travellers. Political geographers conceive the whole of North America to be divided among the three powers of Great Britain, the United States, and Spain, with the exception of such remote or little known districts as are still in the hands of the native tribes; to which, though of scarcely any importance, may be added an extremely small portion on the north-west coast, in the vicinity of Asia, to which Russia may attach a doubtful, and by no means an enviable claim.

The first portion we have to consider occupies the remainder of the isthmus by which North and South America are united. To the whole is sometimes applied the title of Mexico, or New Spain; this last acknowledging the power to which it has been subjected since its discovery by Europeans. But we ought to apprize the general reader, that the application of names to most part of the Spanish possessions in America, has been frequently and variously modified, so as to occasion much perplexity of description.

Mexico lies between the latitudes 7° and 23° N. and the 88° and 107° W. longitude. It is more than 2000 miles long from south-east to north-west, and of very variable breadth. The narrowest part of the isthmus, which is in the district or province of Veragua, is said to be no more than 25 British miles across; but the average breadth may be stated at 400. The mountains of the isthmus, which have been supposed a mere continuation of the Andes, and which are said to be prolonged to the northern continent, are very lofty. Orisaba, for example, is visible at the distance of 60 miles, and many of them are commonly covered with snow; several are volcanic; their courses are extremely varied, but may be said, in general terms, to lie in the direction of the isthmus; and they are the source of many small rivers which run on both sides towards the ocean. The declivities of these mountains are profusely covered with trees, shrubs, &c. of various

North America.

kinds, forming the secure abode of numerous species of birds. Plants, of the finest form and colours, are copiously distributed throughout the lower lands, and contribute to the beauty of this fine region.

The rivers are small, but their numbers promote the fertility of the soil, which, like that of most tropical countries, is more productive of fruits than of grain. The lakes are numerous; and Nicaragua, in the south, is the most important.

The climate of this region is, on the whole, favourable. The extreme heat, to which its situation subjects it, is greatly tempered by frequent rains and the predominance of alpine elevations. But storms are not rare; and the occurrence of earthquakes lessens the weak security of human happiness.

Among the animals of this country are, the porcupine, a species of panther, which sometimes grows to the size of a large ox, the bison, the buffalo, wild goats, wild horses, apes of numerous species, armadillos, snakes of huge magnitude, many curious sorts of birds, &c. The precious metals are found in many districts, and have often been wrought to advantage.

Veragua, though politically attached to the viceroyalty of New Granada, is certainly a part of North America. It adjoins Panama, is very woody and mountainous, and subject to frequent and heavy rains, which render it unhealthy. The population is scanty, and the country has been little explored; yet it is reckoned rich in gold, and possesses one or two good harbours. There are several islands on its coasts. *Costa Rica*, a province to the northward, has its name from its rich mines of gold and silver, which have been abandoned from the difficulty of working them. In its general features it resembles Veragua.

Nicaragua, lying in about 12° N. Lat., is amazingly woody, but has very fertile plains, watered by the river Yare, and several smaller streams. The lake of the same name is about 170 British miles long, and nearly half as broad. Opening into the gulf of Mexico by the river St Juan, and connected, as is believed, with the Pacific ocean, by a little rivulet, this lake seems to court the industry of man to effect a navigable junction between the two oceans.

Honduras, attached to Nicaragua on the north and north-east, is on the whole a flat country, abounding in wood. From the bay formed by this province and the coast of Yucutan, in the gulf of Mexico, is obtained much of the logwood of commerce; and the bay of Campeachy, on the north of Yucutan, furnishes immense quantities of mahogany.

Guatimala is applied both to a small district and to a large province constituted by several districts, forming the third audience of the older division, or sometimes the Commandancy of Guatimala. St Jago, the capital of Guatimala, and seat of the third royal audience, the president of which is amenable to the viceroy of Mexico, was built near the west coast, between two mountains, one of which is a volcano. It was injured by an earthquake in 1751; a similar event took place in 1775, by which the new city, on the same site, was utterly destroyed, when upwards of 100,000 persons were lost. The situation for a capital was afterwards changed. Ciudad Real, the chief city in Chiapa, has some trade in chocolate, cotton, cochineal, sugar, &c.

The Audience of Mexico comprehends seven provinces. *Yucutan*, lies between the bays of Campeachy and Honduras, in about 20° N. Lat.; is nearly 300 miles long, and is sometimes called Merida, from its capital. Cotton, indigo, maize, &c. are the products of this district. There is reason to believe that this country was once under the waters of the ocean. *Tabasco*, to the west of Yucutan, a flat, moist, and rather unhealthy country, is exposed to intense heat, and to rains for about nine months in the year. *Guaxaca*, or *Oaxaca*, is north of the preceding, and occupies the whole breadth of the isthmus. It is very rich in cochineal, produces also silk in abundance, and, on the whole, is more generally fertile than any of the other provinces. The capital of the same name is a large and elegant city, situate in a fine valley, and containing more than 20,000 inhabitants. It is a bishop's see. Gold is found in most of the rivers of this province. Industry on the part of the people is all that is wanting to bring this country, and particularly the capital, to the highest prosperity.

Tlascalà, north-west of the preceding, extends 60 miles along the west coast, and 180 along that of the gulf of Mexico. Though very rocky and mountainous, it has some fine valleys. The people of this province are noted in the history of the conquest of Mexico by the Spaniards, to whom they afforded essential aid. Certain immunities are still enjoyed as the rewards of such services. Puebla de los Angelos, now the capital, is reckoned the second city in New Spain, and is inferior only in population to Mexico. It is said to contain 60,000 inhabitants, is well built, possesses some elegant churches, two colleges, twelve nunneries, and a great many convents. Several manufactories of cotton cloths, earthen ware, iron goods, and soap, which last is so good as to be in great demand even in Spain, have been established. Two towns of the name of Vera Cruz, both in this province, and Xalapà, which gives its name to a valuable root used in medicine, Jalap, found in its neighbourhood, deserve to be mentioned. A curious discovery was made in the northern part of the province about 50 years ago. It is a pyramid, supposed to be of very high antiquity, situate in the middle of a thick forest. Its perpendicular height is about 60 feet, its base an exact square of 82 feet, and it is composed of large stones, nicely polished, and covered with hieroglyphics. No satisfactory explanation of this singular structure has been given, or perhaps can be expected.

Mexico Proper, to the west, or north-west of *Tlascala*, has the Pacific ocean on the south, the small province of Panuco on the north, and is bounded by that of Mechoacan or Valladolid on the west, and is 300 miles long and half as broad. It enjoys a healthy climate, a fertile soil, and is the seat of the capital of all Spanish America. Of this very singular and important city we shall reserve a description for another part of our work. We shall therefore merely mention that Mexico is singularly situate on a lake, displays some superb buildings, and has a population exceeding 130,000. Acapulco, on the coast of the Pacific ocean, is a town long noted for trade, now on the decline. It may be reckoned the port of Mexico on one side of the isthmus, as Vera Cruz is on the other. Queretano, to the north of Mexico, is second to it as to extent in the vice-royalty. It is very beautiful, and contains more than 40,000 inhabitants.

The Audience of *Guadalaxara*, or *New Gallicia*, also comprehends seven provinces, but none of them presents any thing worthy of particular notice.

San Luis Potosi belongs to New Spain. It is on its north-east side, and lies partly on the shore of the gulf of Mexico. San Luis Potosi, the town so called, contains 12,000 inhabitants.

Louisiana extends along the north shore of the gulf of Mexico to the river Mississippi, and indefinitely towards the north, being reckoned, however, about 1,200 miles long, and from 300 to 400 broad. A nominal distinction into Upper and Lower has been applied to this region; in the first, towards the north, a greater degree of cold prevails than is usual in the corresponding latitudes of Europe; and the second is not scorched by excessive heat as those of Africa. On the whole, with some exceptions, the climate is mild, and, unless immediately on the coast, the soil is fertile; but much of the country is covered with forests, and the bulk of it has hitherto been imperfectly cultivated. The population is supposed not much to exceed 40,000, that of Upper Louisiana being, according to Volney, only 2,500, which is extremely disproportionate to the extent. New Orleans, the capital of Louisiana, near the mouth of the Mississippi, is admirably situate for trade, and has made rapid advances in size and importance. New Madrid, up the country, and on the same river, at some distance from the influx of the Ohio, is likely to experience no less a share of prosperity. Indeed, it is scarcely possible to doubt, that this province, to whomsoever it may eventually belong, is destined to acquire a degree of respectability which will render it of essential importance in the scale of commercial nations.

On the west of Louisiana, stretching across the continent to the gulf of California, and beyond the peninsula of that name, to the Pacific, are two provinces, formerly reckoned distinct, but now comprehended in the vice-royalty of New Spain, viz. *New Mexico* and *California*. The progress of these towards civilization has hitherto been so tardy as to furnish scarcely any topic worthy of particular notice, and the reports of travellers are too scanty and imperfect to make up the deficiency. The climate may be declared temperate, and the soil in many places is genial, and well supplied with water from an abundance of rivers.

Unless by navigators on voyages of discovery, the west coast of America, from California to the highest attained north latitude, has been very little visited. These, however, have nearly completed its geography, as may be seen by inspecting recent maps. Our own countrymen have contributed materially to this object. France, Spain, and even Russia, are entitled to the credit of some discoveries; and, of late, the government of the United States appears anxious to promote the knowledge of a coast which may one day minister to their rapidly accumulating energies.

Nootka, or King George's Sound, lying in about 49° 36′ N. Lat. and 126° 42′ W. Long. has attracted some attention, rather because the question respecting the property affected at one time the understanding between Great Britain and Spain, than from its own merits. All claim to it was yielded in favour of the former power in 1790, and about five years afterwards it was taken possession of by the sovereign whose name it bears, since which it seems to have ceased to interest the public mind; but it may prove a point of some consequence, when the United States, in prosecution of views which time is developing, shall have succeeded in establishing a colony at the mouth of the Columbia, to which, it is extremely probable, the late expedition of captains Lewis and Clarke across the continent, was intended to conduce. To the account of this expedition, published from the official report to the American government, we refer for much curious information respecting the countries over which they travelled, and the mighty rivers by which those regions are traversed.

Cook's Inlet, the entrance of which lies in about 60° N. Lat. is distinctly ascertained to have no communication whatever with any coast on the north or east. The hopes, indeed, which had long been entertained, that such a communication between the Pacific ocean and Hudson's bay, or some other sea leading into the Atlantic, would be discovered, may, with perfect confidence, be asserted altogether unfounded as to any point on the west coast of America so high up as has ever yet been reached.

From near the north side of Cook's Inlet, or river, as it is sometimes improperly called, the coast suddenly projects westwards, forming the peninsula of Alashka, or Alyaska, from the extremity of which a chain of islands stretches out so as to approach near Kamtschatka on the continent of Asia. These islands, and the peninsula itself, furnish wretched employment to a race of beings, nominally under Russian protection, but whose calamitous history, as related by captain Krusenstern, in the account of his circumnavigation, would appear to render it doubtful if the intervention of a civilized government had ever been exerted in their behalf. Their occupation is to collect furs from the foxes and other animals which are found in these regions. A more dismal picture of tolerated miseries was never published than what is given in the account by the officer (himself a Russian) now mentioned, of the injustice and barbarous policy to which they are subjected, by a company possessing a legal right to profit by their miseries.

Cape Prince of Wales, in 66° N. Lat. is the extreme north-west point of the American coast hitherto explored. It is little more than twenty miles distant from a corresponding projection in the continent of Asia, the passage between which is denominated after the navigator who discovered it, Behring's Strait.

The highest point reached on the west coast of America, is that of Icy Cape, beyond which captain Cook found it was altogether impossible to proceed, from the multitude and magnitude of the masses of ice that obstructed his navigation.

The whole of this coast is said to bear a great resemblance to that of Norway, especially in the circumstances of its being skirted with inlets, projections, and small islands, and crowned at some distance inland with lofty ridges of mountains. The inhabitants throughout are nearly in a savage state, but divided into various tribes, having various appearances and manners, and often engaged in hostilities with each other.

In passing from Icy Cape, towards the east coast of America, there are few objects to detain our attention. Indeed, the whole of the north coast between that cape and Davis' strait is totally unknown, with the exception of two points ascertained by captain Hearne in 1770, and Mr Mackenzie in 1789, to the published reports of whose travels we must refer for particulars respecting the lands, natives, and productions of these high latitudes.

British Possessions.—The boundaries which are uncertain on the north, are Davis' strait and the Atlantic on the north-east and east, the possessions of the United States on the south-east and south, and may eventually be extended to the Pacific on the west, though the intermediate space, nearly 100° degrees of longitude, be at present almost totally independent of the British empire.

The northern coast of Hudson's bay has been seldom visited, and is too inclement to tempt much enterprise. Even those lands which are round its western, southern, and eastern shores, below the latitude of 60°, present topics only of doubtful interest. Since the discovery of this inland sea, in 1610, by the person whose name it bears, it has been frequently visited with the view of ascertaining the existence of a passage into the western ocean, but always without success. The common opinion, now entertained, that this sea does not afford any such passage, may be considered as demonstrably true. The entrance into the sea from the north-east is by a strait proceeding from Davis' sea, about 600 miles long, and lying between 60° and 63° of latitude, of very variable breadth. This strait is practicable only during summer, and even then not without danger. The bay itself is scarcely navigable above four months in the year, from the prevalence of ice, besides being always hazardous from the number of small islands, rocks, and sand banks. Several rivers open into it; but as their mouths are generally filled with shoals, there are few places on the coast which afford good ground for ships to lie on. The depth of water in the middle has been ascertained 140 fathoms. It is very sparingly supplied with fish. Whales, both of the common kind, and of the Beluga species, are known to frequent it in considerable numbers. This induced the company, who so early as 1670 obtained a charter investing them with the property of a large portion of this region, to establish a fishery. But the expence of managing it, and a variety of difficulties, occasioned its abandonment in 1771.

The lands on the west of Hudson's bay have been denominated New North and South Wales. In general, the soil is so barren as to give no hopes of ever being useful; some very small trees, moss, and occasionally a little grass, are the only vegetable productions, and the inclemency of the weather seems to preclude almost the possibility of improvement.

Fort York, lying between two branches of the river Nelson, in $57\frac{1}{2}°$ of latitude, is the centre of the commerce carried on in this bleak region. To the south-west of this factory, as the chief places of the commercial establishments scattered in this country are called, but at a considerable distance, lies lake Winipeg or Winipec, which receives several streams from the west, some of which are supposed to arise near the source of the Mississippi. The Hudson's bay Company claim the sovereignty of these territories, parts of which, however, are apt to be questioned as the property of the United States. On a part of this assumed property purchased from the Company, and lying on the Red river, the Earl of Selkirk lately attempted to form a settlement of emigrants, chiefly from the Highlands of Scotland. The right of disposal has been denied, and the absurdity of the speculation attempted to be shewn in a letter to his Lordship, by Dr Strachan rector of York in Upper Canada, published in 1816. The opinion that the undertaking was injudicious, is supported by its complete failure.

The eastern coast of Hudson's bay is denominated East Main, and forms a part of the large country to which the Portugueze who discovered it gave the very inapplicable name of Labrador, i. e. Ploughman's Land, but which has been recently called, with as little propriety indeed, New Britain. It is bounded, on the east by Hudson's Bay, on the north by the strait of the same mariner's name, on the east by the Atlantic, and part of the gulf of St. Lawrence, and on the south by Canada. The interior, which is scarcely known, is, in general, hilly and barren. The inhabitants, who are few and poor, are known by the name of Esquimaux, and bear great resemblance to the people of Greenland. They are very peaceable, and as they possess a rather unusual share of docility, have done justice to the zealous exertions of the Moravian brethren, who commenced settlements among them about 1764. Since that time, some tracts have been cultivated and several useful arts introduced, which, with the establishment of a fur trade and fisheries, and certain natural advantages, render this country an object of no inconsiderable interest. A peculiar shining stone, of variable colours, called Labrador spar, is found on the shores of the sea and lakes in this region, but hitherto the parent rocks have not been discovered.

Newfoundland, an island of a triangular shape, about 900 miles in circuit, is separated at its north-west extremity from the coast of Labrador by the strait of Bellisle, which stretches out towards the south and forms part of the gulf of St Lawrence. It is bounded by this gulf on the west and north west, and on the east and south by the Atlantic. Few persons have penetrated into the interior of this island; but its coasts are well known, having been long frequented for its extensive fishery. It is a hilly country, occasionally covered with some of the smaller sorts of alpine trees, &c. The climate is vastly more severe than might be expected from the latitude, viz. between about 46° and 51°, which corresponds with part of France in the Old World. On the banks of the rivers, which are plentiful in this island, good pasture is abundant; and it cannot be doubted, that, in course of time the hand of man will recover the soil from its nearly barren condition. But the chief inducement to visit the island is the abundance of fish off its coasts, so that few families reside on it with any serious intention of promoting its agricultural welfare. The chief towns are, St John's, near cape Spear, on the south-east coast, a small dirty place, with a good harbour; and Placentia, also a small place, in an excellent bay of the same name, on the south coast. The bays and harbours are numerous, and many of them both safe and commodious. The fishing bank of Newfoundland, more precious than a gold mine, lies to the south of the island, and is reckoned more than 400 miles long and 200 broad.

Royal Island, or Cape Breton, in the gulf of St Lawrence, is about 100 miles long, and of very irregular shape, has a cold, foggy climate, a scanty, ungenerous soil, and a population of about 1000 souls. Its coasts are bold, and its harbours somewhat difficult of entrance. Since it was ceded to the British, in 1763, the fortifications which its former masters, the French, had erected in different parts, especially at the port of Louisbourg, on the south-east coast, have been demolished. The fishery, of which this island was the chief seat, and for which alone, perhaps, it is of any value, was calculated to yield the French at one time no less than a million Sterling yearly. There is an extensive bed of coal in the island.

The island of St John, to the west of the preceding, is reckoned 60 miles long and 30 broad; is, on the whole, very fertile, well watered, in a tolerable state of cultivation, and has upwards of 5000 inhabitants. It has been denominated the Granary of Canada; a term which implies at least its comparative productiveness. In many respects it is a highly advantageous appendage to the British dominions in this quarter of the world.

The islands now mentioned are separated by a narrow channel from the province of Nova Scotia, which is connected with the continent by a neck of land at the bottom of the bay of Fundy. It is about 300 miles in length, and, on an average, about 80 in breadth. The soil is unfruitful, except on the banks of rivers, where a little grain, some grass and flax are raised. The climate is cold, and subject to fogs, and cannot be reckoned healthy. The inhabitants are not numerous. Its convenience for fishery is the chief excellence of this province. The timber grown here in large quantities, is generally of a small size, and under the name of lumber is carried to the south. Good harbours abound on the coast; on which the tide is remarked sometimes to attain a very uncommon height, as from 50 to more than 70 feet. Halifax, the capital of this province, is a thriving town, on the bay of Chebucto, and contains 5000 inhabitants. Annapolis, a small town on the south-east of the bay of Fundy, is noted for its safe and commodious port. Most of the other towns in Nova Scotia are very trifling in size, but that of Shelburne was estimated in 1799 to contain about 9000 inhabitants, many of whom were loyalists who had emigrated from the United States.

The province of New Brunswick, which, till 1784, was comprehended under the same name with Nova Scotia, is divided from the territories of the United States by the river St Croix; is watered by a considerable stream, the river St John, which is navigable a good way from its mouth for vessels of 50 tons; has several lakes, one of which is 30 miles long and nine broad, and is traversed on the north-west by a branch of the Appallachian mountains. Fredericktown, on the St John, is the capital.

Canada is bounded on the north by Labrador, the southern coast of Hudson's bay, and that region on the west of the same bay called New South Wales; its eastern limit is marked by the bay or gulf of St Lawrence; on the south and south-east it terminates in Nova Scotia, taken in its largest signification, and the property of the United States; while, on the west, it stretches indefinitely among the little known lands still possessed by independent tribes of native Americans. Its greatest length from east to west is variously reckoned from 600 to upwards of 1000 miles, and its breadth from north to south from 200 to 400 miles. A line, partly imaginary, and partly marked by the river Outawas, or Utawas, divides it into Upper and Lower Canada; the latter being to the north-east of the former, and consequently nearer to the mouth of the St Lawrence.

Soil and climate.—This country, on the whole, is hilly and much covered with trees, having but a thin, and naturally not very fertile soil, unless in some of the plains, especially in Upper Canada, where vegetation is more abundant and the climate milder. The labour of cultivation, however, where skilfully directed, has been tolerably well rewarded by crops of grain and useful vegetation, in addition to some good pasturage. Certain of the smaller fruit trees, too, are found to be productive; nor ought the maple to be forgotten, as affording a saccharine substance much used in the country. Summer and winter run suddenly into each other, with scarcely any intermediate seasons, and the effect of both is amazingly great. Thus, snow falls to the depth of many feet, and the mercury in the thermometer has sometimes been frozen; while, on the return of warmth, a thaw almost instantly inundates the country; and six weeks after sowing his seed, the husbandman is busily occupied in storing up its produce. Such rapidity of vegetation is experienced in other countries where a long and severe winter is suddenly succeeded by a short and warm summer.

Lakes.—The mountains of Canada are numerous, but neither lofty nor arranged in extensive ridges. The lakes form a more striking feature. Three of these, from their vicinity and actual contact, may be considered as composing one body of water, for which, with propriety, the name of the Sea of Canada has been proposed. Of these, lake Superior is said to be 1500 miles in circumference, lake Huron from 900 to 1000; and lake Michigan is reckoned 260 miles long and upwards of 50 broad. They are navigable for ships of any burden, and the water is clear and wholesome; but the storms to which

North America.

they are subject are found no less dangerous than those of the ocean. To the east of these are lakes Erie and Ontario, united by the river Niagara, celebrated for the most magnificent cataract of which we have any correct information. Lake Winipec, to the north-west of lake Superior, is said to be 250 miles long and perhaps half the breadth; and farther towards the north is a still larger lake, called Slave lake, recently discovered. There are probably more than a hundred besides, many of which would be considered of great magnitude in any other country.

Population.—The population of the two Canadas, in 1784, exceeded 120,000, exclusive of savages; and since that period is understood to have considerably increased. The religion most prevalent, and indeed it may be said to be established among them, is the Roman catholic, this country having been colonized by the French, from whom it was obtained by conquest in 1763; but all other religions enjoy unlimited toleration. Since 1791, the political constitution of Canada has borne a near resemblance to that of England, and the laws are almost the same. A legislative council, consisting of fifteen members, for Lower Canada, and seven for the other province, summoned by the king, and appointed for life, under certain conditions, and an assembly of fifty persons returned by the freeholders of Lower Canada, and sixteen by those of Upper Canada, are obviously copied from our Houses of Lords and Commons. Like them they have power to make laws, but the governor-general, who is also commander-in-chief of the army, must give his sanction to their adoption; and, after all, it is competent to the king of Great Britain to declare his dissent within two years from the time of receiving any bill.

Trade.—The commerce of this country has rapidly increased since its connexion with Britain. Before that period the exports were valued at L.80,000 Sterling; in 1769 at L.163,000, employing 70 vessels; in 1795, the trade employed 128 vessels, amounting nearly to 20,000 tons, and navigated by upwards of 1000 seamen; in 1802, the exports, which were principally of grain, employed 211 vessels, of about 36,000 tons, navigated by 1850 seamen; and in 1810, the exports employed 661 vessels, and were valued at L.2,358,000 Sterling; while the imports only amounted to L. 972,837 Sterling. The exports were chiefly of provisions, lumber, furs, ashes, and some drugs; the imports were mostly articles of luxury, or such as have become necessary in consequence of certain habits acquired in the progress of national refinement. This growing commercial prosperity, it is certain, implies the internal improvement of the colony; but there is reason to doubt, when all the expenses and hazards of administration and protection are taken into account, whether Great Britain derives any essential advantage from the sovereignty. The question, however, demands very complete information, and the exercise of much discernment; and after all, perhaps, there is a feeling of national pride engaged in the maintenance of the possession, which would set at defiance the calculations of sound policy. Neither the taste nor the habits of the Canadians, we may observe, seem to offer encouragement for a union with their republican neighbours; and, on the other hand, it is impossible not to conceive the probability of some circumstance of disagreement or temptation occurring, in course of time, to give them the wish for independence. But as yet, we may add, both in point of spirit and of information, to say nothing of means, these people are at least a century behind any of the nations most interested in their political attachment.

Towns, &c.—The principal towns in Canada are Quebec, the capital, on the north-west side of the St Lawrence, a fortified and well built city, containing above 10,000 inhabitants; Montreal, an extremely neat and pleasantly situate town, about 150 miles south-west of Quebec, and nearly as large; York, the new capital of Upper Canada, situate on lake Ontario, near a long peninsula, which forms a bason capable of containing a large fleet; and Kingston, on the north shóre of the St Lawrence, near the same lake. A great number of other towns, and many villages rising into consequence, are at once the cause and the effect of extended trade and manufactures. The character of the Canadians has been variously represented, as the describers were attached to English or French manners; and hence, unless some standard be agreed on, it is impossible to do it justice. We deprecate, for our own part, all partial reports of national features. But a statement of facts must ever compel some degree of regard. Of these we select for notice, the prevalence, or, at least, very common use of the French language, a predilection for gay amusements, very sparing attention to intellectual studies, the superiority of the women in matters of even ordinary education, and the existence of a very large portion of superstition. With respect to some of these points, it is worthy of remark, the British government has exhibited a singular instance of liberality, in affording encouragement to the society of Jesuits established in this country, for some years after every European court had concurred in the destruction of the order, and now maintaining a seminary for the education of Roman Catholic ecclesiastics, by a tax, of the nature of tythes, levied on the inhabitants. Mr Heriot, from whose Travels in Canada we learn this fact, apprises us at the same time of the extension of the benefits of this establishment: "Since the decline and extinction of the order of Jesuits, the seminary, which was at first exclusively designed for the education of priests, and, excepting the college of Montreal, is the only public establishment of the kind in the province, is now open to all young men of the Catholic faith, although they may not be destined for the sacerdotal function." The clergy of the church of Rome established in Canada are, two bishops, three vicars-general, and 116 curates; while that of the church of England amounts to no more than 12 persons.

III. The United States.

The obvious inconsistency which often appears between the political and the natural boundaries of countries is scarcely separable from those vicissitudes of fortune to which nations as well as individuals are exposed. Hence the necessity for frequently revis-

United States.

ing geographical descriptions, and of restricting them to some well known period. A line, partly imaginary, cuts off the British possessions towards the mouth of the river St Lawrence, and another line still more arbitrary, in the parallel of 31°, is supposed to divide those of Spain, viz. East and West Florida, from the United States in the south; while, by cessions not properly understood, and by actual encroachments, these politic republicans have lately obtained footing in Louisiana, on the west of the Mississippi, and are gradually extending their influence across the whole of this northern continent. The particulars of the boundaries, now in a general way alluded to, will be found in Morse's American Geography, to which we must refer for minute information. The territory of the United States, about 1793, contained, by computation, a million of square miles, or 640,000,000 acres, of which 589,000,000 are estimated to be land, and the remainder, or 51,000,000 water. This, however, was exclusive of Louisiana, and since that period there has been a gradual accumulation of country in the interior, or what has been called the western territory. The extent may be stated at 1300 British miles from east to west, towards the northern boundary, and 1000 miles from the lakes of Canada to the limit of Florida on the south. This extensive region presents a very diversified appearance, and possesses great varieties of climate and soil. Some tracts are mountainous, others exhibit immense plains; lakes and rivers are numerous, and there are frequent alternations of rocky districts and rich loamy grounds. Here it may be proper to notice some circumstances which have given rise to several opinions as to the former condition of this country, and to the conviction of many persons that the whole of it, excepting the summits of the hills, was at one period under the waters of the ocean, from which it has gradually or suddenly arisen in consequence of the operation of unknown causes.

Throughout the southern portions of this region, marine shells and substances peculiar to the sea shore, are almost constantly found in large quantities, on digging to the depth of 18 or 20 feet below the surface of the earth. Of this there is a remarkable example on the banks of the Savannah, 90 miles from the sea. In sinking wells in the same places, though at the distance of many miles from the sea, the water first found is sweet and good; but what comes up when the digging is carried on a few feet deeper is so brackish as to be unfit for drinking, and the appearance and smell of the earth resemble those of the mould on the edges of salt marshes. Ridges of sand are frequently found on the margins of rivers, seeming to have been drifted there by the force of water. At the bottom of the banks of some of these rivers, trunks, branches, and leaves of trees have been met with at a depth of 15 or more feet from the surface. These sometimes alternate with layers of sand. Such appearances are known to be presented at the distance of 80 and 100 miles from the sea. The rivers, especially in the south, have often changed their channels; swamps, and grounds which lie low, are constantly filling up, and in many places the land has made great encroachments on the ocean. Dr Morse states, that in the year 1771, at Cape Lookout, in lat. 34° 50′, there was a harbour capable of receiving a hundred sail of ships at a time, in a good depth of water, which is now completely filled up and become solid ground; and such instances, he says, are frequent along the coast. Connected with this curious observation, we ought to add, that there is a gradual descent of about 800 feet, by measurement, from the foot of the mountains to the sea mark, and that it appears to extend still farther into the sea, as has been discovered by successive soundings.

Mountains.—The principal ridge of mountains of this country, to which, from its position, the quaint title of the back-bone of the United States has been given, is better known under another name, the Alleghany mountains. It is merely a part of a series of mountains of the same name, and sometimes called Appallachian, and which lie in a manner intermediate between the ocean on one side and the Mississippi and lakes of Canada on the other. Great part of these elevated regions is incapable of cultivation, but extensive tracts are also to be seen which are noted for arable and grazing land. The hills on the north of the United States, which form in part the separation from the British possessions, give rise to several rivers, some of which run towards the St Lawrence, and others find their way to the Atlantic. A similar distribution takes place farther to the south. But we remark only at present, that, in respect of being well watered, and possessing conveniences for inland navigation, this country may rival any part of the world. If, in addition to those advantages, the number and excellence of the bays and harbours on the sea coast be taken into account, the United States may rank among the most highly favoured of commercial nations.

Climate.—The sudden transitions of temperature, and the great range to which it is liable, render the climate, on the whole, unfriendly to delicate constitutions. But there are many agreeable exceptions, especially towards the south, where the winters are mild. There can be no doubt, that the rapid cultivation of the country which has taken place in recent times, has materially moderated the climate, and still greater improvements may be expected. In general, the seasons correspond as to time with those experienced in Europe, but they are not so steady. The particular direction of the wind is known to have astonishing effects on the weather; but this too is different in different places.

Soil, &c.—The diversities of soil in the United States are, of course, friendly to variety of vegetable productions. Indian corn, a native of America, is found in all the latitudes between the equator and 45° N. but thrives best between 30° and 4°. Rice, which is not a native, is successfully cultivated in some of the southern states. What is known by the name of wild rice is abundant in the interior, and, according to Dr Morse, is the most valuable of all the spontaneous productions. It resembles oats in its stalk, ear, and manner of growth, requires a rich alluvial soil, and yields a bland sweet nutriment. The common European grains are generally cultivated, and there are some others less known. Other roots and garden stuffs thrive in the greatest luxuriance and variety. Fruits of the choicest kinds, and many aromatic substances, are copiously distributed. Medical plants abound. The forests still provide ample store of timber, adapted to every common purpose. In what may be called botanical curiosities, there are few countries which can compare with the United States.

Animals.—The domesticated animals are much the same with those of Europe; and among the wild beasts may be mentioned elks, and varieties of deer, bears, wolves, racoons, beavers, the skunk, the opossum, the porcupine, wild cat, panther, &c. Some of these are unknown in the Old World, but not a few are common to both hemispheres. The list of birds and of insects is very extensive. Forty kinds of serpents, of which the rattlesnake may be considered the most formidable, have been enumerated. The rivers are well supplied with fish. Frogs of great size, and capable of great powers of voice, swarm in some of the marshy places; and alligators are not rare, especially in the south.

Minerals.—The mineralogy of the United States has not been accurately or widely explored. In a few places, some of the precious metals are sparingly found; copper is occasionally met with; lead and iron exist in abundance; and some of the other metals are frequently discovered. Coal is not so plentiful as to render it unnecessary to have recourse to foreign countries for supply.

Population.—The population of the United States, in 1790, was estimated at 3,930,000, exclusive of about 20,000 to the north-west of the Ohio. In 1801, the date of the last census, the number, including the inhabitants of the Ohio territory, amounted to 5,260,463, of which the slaves formed 894,452. This was exclusive of the inhabitants of Louisiana, computed to be 42,375. By the same rate of increase, or according to the opinion generally adopted, that the population of the United States doubles in 20 years, the number of inhabitants may now (1816) be estimated at 9,000,000. The bulk of this population, it is well known, is the offspring of persons who emigrated at various periods from the British islands; and the language still used by them is that of the parent country. The exceptions are the descendants of Germans, French, Dutch, and Swedes, whom different motives induced to seek an asylum in the uncultivated tracts of this inviting country.

Natural Division.—According to Volney, there are three great natural divisions of the country comprehended under the name of the United States. The first portion lies between the coast of the Atlantic ocean and the Alleghany mountains; the second is that which is covered by these mountains; and the third extends to the westward in the direction of the Mississippi. This division is undoubtedly natural, and for the purposes of physical geography may justly be preferred to any other; but the common division is into Northern, Middle, and Southern States.

Northern States.—The Northern States, often called New England, consist of the *District of Main*, *Vermont*, *New Hampshire*, *Massachusetts*, *Connecticut*, and *Rhode Island*. The general boundaries of this assemblage are, Canada on the north; Nova Scotia, in its largest acceptation, and the Atlantic on the east or north-east; the Atlantic and Long Island sound on the south and south-east; and the state of New York on the west.

Surface of the country.—This country presents a beautifully variegated appearance, having all the changes of hills, vallies, forests, rivers, and cultivated tracts, which are necessary for picturesque effect. The mountains are not of great height, but are very numerous, and often run in parallel lines nearly north and south. From these issue rivers and streams at very short intervals, so as to water and fertilize every part of the land. Some remains of merely natural scenery contrast finely with the comfortable indications of human labour.

Character of the Inhabitants.—An abundance of most kinds of useful grains, excellent fruits, and pasturage, rewards the industry of the numerous and intelligent population; altogether, indeed, the bounties of nature, and the effects of civilization, seem so well proportioned to each other, and to be enjoyed in so high a degree, that New England has become an object of universal admiration. Is it to be wondered at that the people themselves are alive to the same impression, and are more earnest in expressing its existence? Nothing but envy, we apprehend, could censure their habit of thinking themselves the happiest and most rationally free of the human race. But to this disposition they add a failing, apparently at variance with it, but, in fact, its almost essential companion. This we shall state in the words of Dr Morse, who is not likely to be thought either defective in information, or inclined to make it subservient to any malicious purpose: "A very considerable part of the people have either too little or too much learning to make peaceable subjects. They know enough, however, to think they know a great deal, when, in fact, they know but little. Each man has his independent system of politics; and each assumes a dictatorial office. Hence originates that restless, litigious, complaining spirit, which forms a dark shade in the character of New Englandmen." "This litigious temper, (he continues, with, perhaps doubtful accuracy,) is the genuine spirit of republicanism; but it denotes a corruption of virtue, which is one of its essential principles." The whole picture which this gentleman has drawn, deserves to be commended to the reader's notice. Every religion is alike free in New England; and no peculiar profession of any is either an advantage or a disqualification in respect to public situation. Learning and the fine arts are encouraged by the institution of universities, schools, academies, &c. and by the general regard of the people, who hold ignorance in contempt. The importance and wealth of the country may be safely inferred from the number and appearance of the towns spread over it.

Towns.—Boston, in the province of Masachusetts, is the capital. It is situate on the coast, in front of a safe bay, capable of containing 500 vessels at anchor. The wharf is said to be superior to any in the United States. In 1800, this city contained about 20,000 inhabitants. Salem, which lies fifteen miles north-eastward of Boston, has not so good a harbour, but carries on a very extensive trade, and

United States.

has about 10,000 inhabitants. Worcester, about 47 miles westward of Boston, is reckoned one of the largest inland towns in New-England. Newbury-Port, Hadley, Northampton, Hatfield, Deerfield, Concord, Cambridge, all belonging to Masachusetts, are pretty considerable places.

Portsmouth, the largest town in New-Hampshire, has an admirable harbour, is well built, and pleasantly situate, and contains nearly 6000 people. Exeter, Dover, Amherst, in the same province, are not so large. In 1776, there were 165 settled townships in this state, and the number has rapidly increased since that period.

Bennington, the capital of Vermont, is a thriving town. The inhabitants of this state are chiefly emigrants from Massachusetts and Connecticut, or their descendants; and a settlement of Scotch people are almost the only foreigners in it.

In Rhode-Island, which is reckoned the "Paradise or Eden of New-England," on account of its healthy climate, great fertility, and fine women, there are, besides smaller places, Newport, a prosperous town, having an excellent harbour, and above 6000 inhabitants, and famed for one of the best fish-markets in the world; Providence, a smaller town, but thought to be still more flourishing, built on both sides of a river of the same name, and boasting of a college under a baptist president; and Bristol, 16 miles north of Newport, possessing a good harbour, and noted for its crops of onions.

Dr Morse's account of this state, we may add, presents some very strange peculiarities, not calculated on the whole to excite agreeable impressions, or very high respect towards its inhabitants.

Connecticut has a great number of towns both maritime and inland. Hartford, about 50 miles from the mouth of the river Connecticut, is a rich commercial city. Norwich, at the head of Thames river, enjoys great advantages for trade, and begins to assume consequence as a manufacturing town. New-London, near the entrance of the same river into Long-island sound, has the best harbour in the province. New-haven, at the head of a bay farther up the sound, for pleasantness of situation and salubrity of climate, is not excelled by any city in the United States. It carries on a respectable trade; and is one of those places of which there is authentic evidence that the population has doubled in periods of about 20 years.

Stratford, Lichfield, Farmington, Middleton, and several other towns, would require particular notice in a minute description of this valuable and prosperous state.

Each of the provinces of New-England now enumerated is divided into counties, and these again are subdivided into parishes, as is common, indeed, to all the states of the Union.

Middle States.—The Middle States are, *New-York*, *New-Jersey*, *Delaware*, and *Pensylvania;* to which are added, the western territories of *Ohio* and *Indiana.*

New-York, the most northerly state, is about 350 miles long and 300 broad. It is a good deal intersected by ridges of mountains and hills, covered with timber of various kinds, but has many vallies of great extent, affording good pasturage, and admitting very profitable culture, and is abundantly watered by a multiplicity of rivers and streams, of which Hudson, Mohawk, Onondago, Delaware, Susquehannah, Seneca, and Chenassee, are the chief; besides containing several lakes, some of which have a communication with lake Ontario, on the western side of the state. The climate is more temperate than that of New-England, but, on the whole, the country is not so well cultivated. This province, at one time, exhibited in a small compass the features, manners, religion, and languages, of a considerable variety of nations. But of late years a greater uniformity has taken place; and probably, in the course of a little time, a sort of national character will be assumed. The English language, by much the most extensively used, has suffered corruption from the contiguity of Dutch and other tongues, and will require, perhaps, more serious and constant endeavours, in order to be restored to its purity, than it can be the cordial inclination of so discordant a race to bestow.

New-York, the capital of the province, and at one time the seat of the general government, is built at the mouth of Hudson's-river, where there is a large commodious harbour. It is the most commercial city in the United States, and is said to contain above 80,000 inhabitants, who are in general noted for their gaiety and social manners. Albany, also on the Hudson's river, 160 miles north of the capital, displays a remarkably heterogeneous collection of people, among whom, it may be observed, the peculiarities of the Dutch character are most conspicuous. Hudson, 30 miles below Albany, is said to have had the most rapid growth of any town in the United States, with the exception of Baltimore in Maryland.

The other towns in this province have scarcely attained any importance to require being noticed in this sketch. York-island, Long-island, and Staten-island, belong to New-York, and are of considerable consequence, especially Long-island, which is divided into three counties, and contains a good many little towns and villages.

New-Jersey, a small state, lies to the south-east of New-York, mostly along the coast of the Atlantic, on which there are several bays. Its western boundary is the Delaware, by which it is separated from Pensylvania. In length it may be reckoned 160 miles, and in breadth 52 miles, containing about 8320 square miles. The climate resembles that of New-York, and the country is similarly diversified with hills and vallies, but not in such extensive tracts as in that state. The chief range of hills is about 600 feet above the level of the sea; and much of the soil towards the coast is sandy, having the appearance of maritime origin. The rivers are numerous, though not large; but the Hudson on the north-east, and the Delaware on the west, secure an extensive trade with the capitals of New-York and Pensylvania, beyond which the inhabitants seem not very desirous of urging acquaintance. They are a very mixed race, and still retain distinct evi-

United States.

dences of their respective origins. Certain peculiarities, too, are said to result from the circumstance of their commercial connexions. Hence the people in the western part of the state, who trade with the capital of Pensylvania, assume the fashions and manners of that place; and those, again, on the eastern side, are regulated, for a like reason, by the maxims prevalent in New-York.

All sorts of religious sects are to be met with here; but the Quakers, Baptists, and Episcopalians are most numerous. Great regard is shewn in New Jersy to the cultivation of learning; and accordingly there are two colleges in it, well endowed, besides many respectable academies and schools. Out of a number of small towns in this state it is difficult to select any meriting peculiar distinction, so close is their resemblance in size and consequence. Trenton seems to be the largest. It is situate on the north-east side of the river Delaware, and is a place of some trade. Burlington, on the same river, but nearer the mouth, is a neat thriving town. Perth Amboy, Brunswick, Newark, and Shrewsbury, are places gradually acquiring consequence.

Delaware, to the south-west of New Jersey, is a much smaller province, consisting of low flat lands of moderate fertility, and exposed to a rather unhealthy climate. Its trade is not very extensive, and it has few places of any note. Dover is the capital, but Wilmington is the largest town.

Pensylvania stretches westward from New Jersey and part of New York, in the form of a parallelogram, about 288 miles in length from east to west, and 156 in breadth from north to south. Its north, south, and west boundaries, are constituted by arbitrary lines. The country is mountainous in the centre and towards the east, flatter on the west, is susceptible of successful cultivation, and possesses abundance of rivers and streams, to which, in great measure, must be ascribed its excellent pasturage. In point of climate it resembles Connecticut in the same parallel, but has the advantage of greater steadiness. On the whole, however, it is not very healthy, owing, it is thought, to the superabundance of moisture, which is very apt to be loaded with noxious miasmata. The proper cultivation of the lands, it is not to be doubted, will in time effect a beneficial change. The population, notwithstanding, is continually on the increase; but this is occasioned, in a great degree, by the influx of people from other countries. The inhabitants, in general, are the descendents of emigrants from the British islands and Germany, and are estimable for their patient industry and sober habits, allied, however, very often, it must be mentioned, with a contracted parsimonious disposition, and a kind of uncourteous reserve. The religion of the greatest part is that of the Friends or Quakers; but all other sects are alike in possession of the most perfect freedom. It will readily be admitted then, that contrasts, amounting almost to a ludicrous extent, are not unfrequently exhibited among this motley people.

To the honour of this province, it ought to be mentioned, that there are more numerous and flourishing societies for literary and humane purposes than in any of the other states.

Philadelphia, the capital, is built according to a regular plan, on a flat between the Schuylkill and Delaware rivers, but it has not been completely executed. The number of inhabitants in 1800, was reckoned at about 50,000, and it is supposed to be on the increase. They are not thought to be remarkable for hospitality, or the qualifications usually looked for in ordinary social companions; but in regard to all kinds of mercantile concerns, and in zealous well directed exertions to promote some of the most essential interests of mankind, Philadelphia may not scruple to compare with any city in the world.

Lancaster, 66 miles north-west of Philadelphia, is reckoned one of the largest inland towns in the United States. The Moravian brethren, as they are called, have several settlements in this province.

The western territory of *Ohio* and *Indiana*, reckoned with the middle states, is much more connected as to position with Virginia, one of the southern states. Hitherto it is but sparingly cultivated, and does not present any topic requiring our immediate attention.

Southern States.—The Southern States, which alone remain to be mentioned, are *Maryland*, *Virginia*, *North Carolina*, *South Carolina*, *Kentucky*, *Tenassee*, and *Georgia*.

Maryland is bounded on the north by Pensylvania, on the east by the state of Delaware, on the south-east and south by the Atlantic, and on the south-west and west by Virginia. It is 134 miles long and 110 broad, containing about 14,000 square miles, a sixth part of which is water. The climate is mild, and in the hilly part of the country healthy; but the marshes and stagnant waters of the flat country subject the inhabitants to intermittent fevers. Chesapeake bay, which is the largest bay in the United States, divides this country into two portions, the eastern and the western. The state has several rivers. Wheat and tobacco are the staple commodities of Maryland; and, in the interior, hemp and flax are raised in considerable quantities.

The inhabitants, who are chiefly of the Roman Catholic religion, live commonly on their plantations, at several miles distance from each other, and are represented as rather indolent and slovenly. But there are many exceptions, and some of the towns exhibit a very enterprising community. The chief towns are, Baltimore, reckoned the fourth in size and the fifth in trade in the United States; Annapolis, said to be the wealthiest town of its size, situate about 30 miles south of Baltimore; Fredericktown, a thriving inland place; and Hagarstown, little inferior to it.

On a neck of land, ceded by Virginia and Maryland to the United States, the foundation is laid for the seat of government, denominated, in honour of a character immortalised in the history of America, and indeed of the human race, as one of its greatest ornaments. This city of Washington, already far advanced, on a regular and beautiful plan, promises, when finished, to be one of the finest cities in the world, and appears to be in possession of certain local advantages, which, independent of political considerations, will go far to ensure its continued prosperity.

Virginia, bounded on the east by the Atlantic, on the north by Pensylvania and the Ohio, on the west by Kentucky, and on the south by North Carolina,

United States.

is about 400 miles long, and upwards of 200 broad. It is divided by the Potomack, Rapahannock, York, and James rivers, has a healthy climate, subject however to great heats, and possesses a fertile soil, especially on the flat lands. The staple commodity is tobacco; but the country, with proper treatment, is capable of producing all the necessaries, and many of the luxuries of life.

This state has produced some of the chief characters in the history of United America, but the people in general are not supposed to concern themseves much with political affairs. A few persons, it is remarked by Dr Morse, appear to have obtained, and continue to exercise a sort of ruling influence over the majority; and thus their government, though nominally republican, is, in fact, oligarchical, or aristocratical. Hospitality bordering on ostentation, a liveliness of manners degenerating into licentiousness, an attachment to pleasures scarcely susceptible of check from the clearest conviction of its ruinous consequences, and a sort of national pride which rather seeks for indulgence in the memory of past times than prompts to excel them by new and nobler efforts, render the Virginians a people more interesting than amiable, and yet more amiable than worthy of respect.

Richmond, built on the north side of James river, is the capital; but it is neither very elegant nor very populous. Norfolk is the principal port in this state. The other towns are in general small, but some of them promise rather rapid augmentation. The population of Virginia is probably not much short of one million.

North Carolina lies to the south of Virginia, having the Atlantic on the east, Tenassee on the west, and South Carolina on the south. It is about 400 miles long and 110 broad, and, in 1810, the population exceeded 563,000 souls. It possesses a mild climate; the heat of summer is moderated by agreeable breezes, and the cold of winter is chiefly confined to the evenings and mornings. In some parts of the country, owing to the flatness and moisture of the lands, diseases of debility are not rare in the warm months; but still more frequent are inflammatory complaints during the winter, occasioned, it is believed, by intemperate habits, too common in this state, and by incautious exposure to the weather. The soil is generally good, answering for tobacco, and productive of a vast variety of trees, grains, herbage, medicinal plants and roots, &c. A particular species of pine, affording pitch, tar, turpentine, lumber, &c. constitutes at least one half of the exports of this state, and may be called, therefore, its staple commodity. Most of the towns are small, and built of wood; and none of the rivers by which this state is watered will admit vessels of more than 80 tons burthen.

South Carolina, in many respects, resembles North Carolina, with which it was at one time united. Its position is similar, partly on the sea coast, and partly stretching inland to the western territories. It is about 300 miles long and 125 broad; its population, which is rapidly on the increase, was 240,000 in 1791. Much of the country is flat and low; and as it is frequently overflowed with water, for the sake of cultivating rice, a prime article in this state, the air is loaded with moisture and becomes unhealthy. There are four navigable rivers in South Carolina, besides many small streams. The vegetable products are much the same as in the northern state. Charlestown, the only considerable town in South Carolina, at the confluence of Ashley and Cooper rivers, on a piece of flat land, is regularly built and fortified, and possesses a commerce inferior in amount only to New York, Philadelphia, and Boston. Its inhabitants, reckoned in 1791 to be 16,359, are respected throughout the whole of the United States, for their hospitable, kind disposition, and the unaffected but elegant simplicity and ease of their manners and address. The Carolinians in general are entitled to such commendation, but it is impossible to bestow it without feeling regret that there should be any drawback to compel animadversion. The employment of slaves, which is common to the southern states, seems to have engendered a haughtiness of behaviour among the *better* kind of people, and to have fostered an indolently luxurious disposition, by no means favourable either to the happiness of the individual possessors or the welfare of the community.

Barbarous amusement.—To what perversity of feeling, or worse than brutal taste, must we ascribe the prevalence, in the Carolinas and Georgia, of a species of amusement in which the parties, engaged seriously, endeavour to put out one another's eyes? None of our readers, we are convinced, can peruse a recital of the mode by which this feat is accomplished, without experiencing unutterable horror and indignation. Dr Morse, whose description we shall quote, speaks of it as if it were confined to the lower orders of people; but this does not exculpate the government from indifference to the shocking enormity. Besides, if we reason from what is known of the satisfaction and readiness with which, in other countries boasting of their humanity, many persons of the higher orders bring themselves to sanction the cruel propensities of the vulgar, we shall not hesitate, independent of other evidence of a positive nature, to believe that more are gratified by the spectacle than can be furnished with a shadow of excuse against the charge of being as savage as they are either poor or ignorant. "The *delicate* and *entertaining* diversion, with propriety called *gouging*, is thus performed. When two *boxers* are wearied with fighting and bruising each other, they come, as it is called, to *close quarters*, and each endeavours to twist his fore-fingers in the ear-locks of his antagonist. When these are fast clenched, the thumbs are extended each way to the nose, and the eyes *gently* turned out of their sockets. The victor, for his expertness, receives shouts of applause from the sportive throng, while his poor *eyeless* antagonist is laughed at for his misfortune." Mr Janson, who has published an account of his observations during a considerable residence in America, bears testimony to the accuracy of this statement, from his having once been present at the barbarous sport. "Passing, in company with other travellers," says he, "through the state of Georgia, our attention was arrested by a gouging match. We found the combatants, as Morse describes, fast clenched by the hair, and their thumbs endeavouring to force a passage into each other's eyes; while several of the bystanders were betting upon the first

United States.

eye to be turned out of the socket. For some time the combatants avoided the *thumb-stroke* with dexterity. At length they fell to the ground, and in an instant the uppermost sprung up with his antagonist's eye in his hand. The savage crowd applauded, while, sick with horror, we galloped away from the infernal scene." We would not conclude this subject, however, without expressing our belief, that such diabolical practices are less frequent than formerly, and our hope, founded on the almost certain effect of the universal detestation excited against it in the civilized world, that in a little time the feelings of humanity will no more be outraged by proofs of its commission.

Georgia, lying to the south of Carolina, and bounded on the east by the Atlantic, on the west by the Mississippi, and on the south by Florida, is reckoned 600 miles in length from east to west, and 250 in breadth from north to south. It is healthy in the hilly country, where the climate is pretty uniform and temperate, but in the flat lands, the warm, moist air, often loaded with putrid effluvia from the marshes, is injurious to the constitution, and together with the nature of the water, which is generally brackish, brings on bilious and intermittent fevers during the summer, and these again are liable to be succeeded by pleurisies and other inflammatory complaints in the winter months. The face of the country, and most of the productions of the soil, resemble or are the same as those in South Carolina. Industry and proper management seem all that are required, both to augment the salubrity of this country, and to render it the vineyard of the United States.

The rapidity with which population has increased of late years, can scarcely be accounted for without supposing a great influx of persons from other regions, who must consequently have had a flattering opinion of its capabilities, and in reality be confirmed in it by experience. According to Dr Morse, the emigrations from Europe, the Northern States, and the back parts of Virginia and the Carolinas, were so great immediately after the peace of 1783, as more than to triple the number of inhabitants in the short space of six years. In 1791, the population was estimated to be 82,548; and in 1810 at 252,433; a difference which we believe to be unparalleled in the history of any other country.

There are several rivers in this state, of which the Savannah is the most noted; and about 60 miles to the south of its northern boundary, the Alleghany, or Appallachian mountains, terminate in an extensive plain, covered with a soil of great fertility, and said to be suitable to most of the productions of the East Indies.

The chief towns are, Savannah, Louisville, Augusta, Brunswick, and Frederica; and on the coast are some useful islands, as, Skidaway, Wassaw, Ossabaw, &c.

Great efforts have been made to promote literature and the useful arts in Georgia, though still in its infancy. The interests of religion also have not been defrauded of the regard due to their importance.

Kentucky and Tenassee, the only states which remain to be noticed, are recent acquisitions to the union, and hitherto have been but imperfectly cultivated and described. The former, properly speaking, is the back-settlement of Virginia, and the latter that of North Carolina, to which states respectively they bear some resemblance in point of soil, climate, and natural productions. Kentucky is farthest advanced in population, reckoned at no less than 406,511 in 1810, and in the number and size of its towns, of which Lexington, situate about 60 miles south-east from the conflux of the Kentucky river with the Ohio, is the chief.

Tenassee, which is to the south of Kentucky, having the Mississippi for its western boundary, the states of South Carolina and Georgia on the south, and North Carolina on the east, is a very extensive tract of land, with a fertile soil, and a climate of superior mildness and salubrity. The population which, in 1795, amounted to nearly 80,000, is on the increase, and may be expected to receive vast accessions from without, when the native tribes, who prove occasionally troublesome, and sometimes destructive, in all the western territories, are either entirely brought to subjection, or can be induced to maintain a permanent and secure alliance. Knoxville is the capital of Tenassee, a small but thriving town, built of wood.

We may here take a cursory glance of a region which is at present under the dominion of the Spanish nation, but which has often changed masters.

Florida, the country now alluded to, is bounded on the north by Georgia, on the east by the Atlantic ocean, on the west by the river Mississippi, and on the south by the gulf of Mexico. In length, from east to west, it is reckoned to be from 500 to 600 miles, and from 100 to 400 miles in breadth from north to south; the greatest extent in this direction being at the eastern side, where a considerable projection into the ocean forms an inclosing bank to the Mexican gulf.

Florida is divided into West and East by the river Appalachicola, which flows into St George's sound, the river St Mary and an imaginary line separating both from the territories of the United States. The climate throughout is very like that of Georgia, and as to soil this region is no less various than that state. The eastern parts are less fertile; yet even in them it is common to have two crops of Indian corn in the year. Fruits and vegetables of many species are also abundant, and some parts of the country are peculiarly valuable as ranges for cattle. Of the amount of the population, and many other interesting subjects respecting this country, we have had but scanty information since it has been in the hands of a people noted for their silence and cautious reserve on subjects of general policy. Pensacola, the chief town in West Florida, stands on a bay forming a commodious harbour, where vessels may ride secure from every wind. St Augustine, on the coast of the Atlantic, a fortified town, of an oblong figure, inclosed with a ditch, is the capital of East Florida.

American Revolution.—A relation of the most important circumstances which eventually led to the separation of the United States from the British do-

United States.

minion, and their establishment as an independent power, naturally follows the description which we have now given. In the following sketch, by retracing the history of these regions somewhat farther than at first sight may seem necessary, we shall, perhaps, discover a striking connexion between some remoter transactions, comparatively of a trifling nature, and others, which, both because they are more recent, and of greater visible magnitude, have attracted a larger share of attention.

Grants of lands.—All the Europeans who successively visited America in the progress of its discovery, agreed in this, that they had *a right* to possess themselves of such places as were not previously seized on or occupied by other Europeans. The kings of England, France, Spain, &c. made grants of lands to their subjects, as if they had acquired the sovereignty of them in the common course of patrimonial inheritance, and apparently without any apprehension of injustice or informality, saving what might arise from the circumstance of similar grants having been previously executed. Some difficulties in adjusting the terms of these deeds, or putting them into operation, were occasionally experienced, in consequence of ignorance of prior deeds, cotemporaneous discovery, or former abandonment by other powers. These difficulties were insignificant in many instances, because the disputed lands being unproductive, or requiring both time and expence for their improvement, did not hold out a reasonable ground for jealousy, far less a justifiable cause for animosity. Very different was the case, when, in the progress of population, and the extension of commerce, these distant settlements began to re-act on the powers by which they had been formed. Old claims were then revived with pertinacious alacrity, and their validity appearing as decisive as their importance was seducing, rival nations prepared to maintain them by force of arms.

War from 1739 *to* 1748.—The war between England and Spain, in 1739, arose from a question of *right*, claimed by the subjects of the former power, to cut logwood in the bay of Campeachy, in which they were frequently interrupted and exposed to capture by the Spaniards. It was carried on with various success, and involved other continental powers, for several years. A termination was put to it by the preliminary treaty of Aix-la-Chapelle in 1748, by no means to the credit of British diplomacy, though certainly not too early for British necessities. Some conquests made in North America, particularly that of Cape Breton, were given up, and the right of navigating the American seas, without being subjected to search, which, in fact, was the original source of disagreement, was never so much as mentioned. The French, who had taken part in the contest, remained in possession of Canada, the limits of which were imperfectly adjusted; and they claimed, besides, the whole of the country on both sides of the Mississippi, and a great deal of Florida, between which and their northern settlements they had established a communication by a line of forts.

Conquest of Canada.—The peace was neither very cordial nor of long continuance. Disputes arose with the French, as might indeed have been expected, from the nature of their claims, and their offensive measures to effect a trade with America. Both powers made vigorous preparations for a renewal of hostilities, but the king of England did not publish his declaration of war till 1756, and not until he had endeavoured, by several mediatory steps, to render it unnecessary. The counter-declaration of the French monarch was expressed with unusual acrimony, and all things presaged a spirited and obstinate collision. Though ostensibly undertaken for American interests, the succeeding war was not entirely, nor indeed chiefly carried on in the New World, but affected the continent of Europe and the dominions of the contending powers in the East Indies. Of four expeditions equipped against the French in North America, during the early part of the war, three completely failed, to the great mortification of England; the operations of 1757 were, if possible, still more disastrous; the next campaign, though far from being very successful, was somewhat encouraging; the advantages gained were improved during 1759, under the brilliant administration of the elder Pitt, and by the bravery and skill of Wolfe, who terminated his short career of glory on the heights of Abraham; and, notwithstanding the utmost exertions of the French to retrieve their losses, the whole of Canada fell into the hands of their enemies during the following year. The peace of 1763 confirmed the British in the possession of that extensive region, and indeed of the whole of North America east of the Mississippi, with the exception of an inconsiderable portion of country towards the south.

Effects on the colonies.—This conquest was made at an expence vastly greater than its real value, and entailed consequences of vital importance to Britain and her transatlantic colonies. It is of these we have now briefly to treat.

The war had been commenced and prosecuted, in a great degree, with a view to the defence of those provinces which had been settled on the eastern coast of North America, and which were perpetually exposed to attacks from the French and the Indians in alliance with them, on their northern and western frontiers. It seemed reasonable that part of the burden should be borne by those whose benefit was thus intended; and accordingly the colonies were by no means backward in fulfilling requisitions for men and money, while the danger by which they were threatened prompted them to make partial sacrifices. They had previously, however, shewn an aversion to be taxed by the parent kingdom, alleging their non-representation in parliament as a reason for their exemption; and, in fact, had cautiously avoided every acknowledgment of the right of taxing on the part of the British legislature. Even the alarming condition of their affairs at the outset of a war, for which they were so ill prepared, failed to seduce them into any measures of acquiescence that might afterwards be appealed to as precedents. The monopoly of their trade, at this time very extensive and still improving, might be held, they probably thought, as an adequate compensation for any parental solicitude or assistance which they had hitherto experienced, or were likely to require. But no sooner

United States.

was the war over, than the colonies felt themselves completely disburdened, both of gratitude and danger, while, on the other hand, the financial embarrassments of the British government, which had been continually augmenting during an impolitic and mismanaged contention, instigated to the adoption of some new expedients for an increase of revenue. Nor were there wanting other causes of irritation to aggravate the unhappy discordancy that now arose, some of which alone might have alienated the weakened affections of the colonists. Their trade, for example, was shackled by the frequent interference of sea-officers, most injudiciously employed in the service of the revenue; and a gainful intercourse, which had for some time existed between them and the Spanish and French settlements in different parts of the New World, was either forbidden, under the erroneous allegation that it was injurious to the interests of the mother-country, or was so much clogged by conditions and duties as rendered it nearly altogether unprofitable. The effect of this impolitic check was so immediately visible, as, if some extraordinary delusion had not seized the British people, would have been sufficient to give warning of the evils to be derived from intermeddling in their concerns. To use the language of the times, the children now resolved to live as much as possible independent of their mother, and accordingly commenced a system of parsimony in the use of articles formerly obtained from her, and of active exertions to improve their own resources. This determination was immensely hurtful to the exports from Britain, which had about this time been estimated at three millions Sterling, not to mention the benefits accruing from the transmission of goods. There needed but a single spark to give agency to such combustible materials as henceforth accumulated in both countries, and this was not long to be sought for.

Stamp-act resisted.—In the session of 1764, the House of Commons, besides laying new duties on their foreign trade, voted, apparently without opposition, "that, towards farther defraying the necessary expenses of protecting the colonies, it may be proper to charge certain stamp-duties upon them." No measure, however, was instantly founded on this decision. The agents of the colonies, then in London, were given to understand, that proposals would be received from their principals for any other tax, in place of the one projected, that might be equivalent in produce; or that, by agreeing to it, they should in future be consulted before taxes were imposed on them by parliament. But not one of these agents was empowered to consent to such a tax, or to offer any equivalent for it. Their constituents, when apprised of such suggestions, appear in general to have considered them as insults; and some of them, in petitions addressed to parliament, directly questioned the authority which had thus been assumed over their property. It seems extraordinary, that these symptoms of refractoriness were not more seriously contemplated by the legislature, as ominous of a fatal convulsion, should the proposed treatment be carried into effect. Several members in opposition now exerted themselves against the measure; and almost every evil which afterwards followed, was predicted with the eloquence and gloomy interest of prophecy. But in vain. The ever memorable *stamp-act*, as it was called, passed on March 22. 1765, having, in consequence of his Majesty's illness, received his assent by commission.

The Americans, without altogether abandoning hope that their remonstrances would avail, were not very much surprised at this event. It had been sufficiently anticipated by them, in consequence of the previous discussions, to give rise to speculations and emotions most inimical to the act itself, and to their political connexion with the mother country. All the provinces, it is certain, were not equally irritable; so that although, by newspapers and other means, any intelligence which affected their common interests spread rapidly among them, yet it was of some relative consequence that one of them should be first apprised of the act having passed, in which less opposition might reasonably be contemplated. If choice, then, or judgment had been permitted, one of the southern provinces would no doubt have been preferred for the place of earliest communication. Unfortunately, the important tidings first of all reached New-England, in which, for reasons elsewhere assigned, there existed a strong remembrance of ancient grievances, and an apathy, if not a positive aversion towards the parent state. Angry feelings and hostile sentiments instantly broke forth; extraordinary means were resorted to for the purpose of provoking opposition; and it became perfectly evident, that every individual thought himself engaged, by invincible obligations, to exert his whole strength and influence against such presumptuous enactments. Readers of the present day cannot but be somewhat amused with the recital of the various devices, serious and comic, in which this opposition displayed itself. We shall sum them up nearly in the words of Dodsley's Annual Register, which must be allowed the merit of having early given warning of the probable catastrophe. Ships hung out their colours half-mast high, in token of the deepest mourning; the bells rang muffled; the act itself was printed with a death's-head affixed to the place where the stamp is usually placed; and this was publicly paraded through the streets, by the name of the "Folly of England, and Ruin of America." The newspapers were filled with essays and animadversions of all sorts, to spread the delirium. One of these, with a very significant title, exhibited the more significant emblem of a snake cut in pieces, each of which had one of the initial letters belonging to the names of the several colonies, from New-England to South Carolina inclusive, and having above them the words, JOIN OR DIE. Caricatures, puns, &c. &c. were added in abundance; and by being very expressive, and easily remembered, admirably served to condense, preserve, and propagate the logic and venom of the multitude. More important, because *official*, demonstrations of the same spirit afterwards appeared; and, in short, such was the determination and energy of all classes of the population, that by the 1st of November, when the act was to take effect, there was not a single sheet of stamped paper to be had throughout the colonies of New-England, New-York, New-Jersey, Pensylvania, Virginia, Maryland, and the Carolinas,

United States.

with the exception of a small parcel, which the governor of New-York had surrendered to the corporation of that town, on condition of its not being destroyed like the rest. A great deal of business was now abandoned, or became illegal, in consequence of this defect; and the governors, at last, apprehending more mischief from its cessation than the informality, pretty generally agreed to dispense with the stamps, which were thus virtually given up. But, before this time, the colonists considered themselves almost totally released from their allegiance; and by various expedients had at last discovered, what at one time would have seemed impossible, that they could exist and prosper without the partiality and produce of Britain.

The obnoxious act was repealed in the following year; a concession which of course was held as a triumph of the most gratifying kind, and which did not fail to foster the infant but strenuous efforts of the aspiring Americans. Old habits, however, besides obvious and very natural prejudices, operated in restoring a liberal commerce with the parent state, and undoubtedly might have secured a pacific, if not a cordial adherence. But Britain, not at all profiting by experience, and probably presuming on the strength of the attachment, and at all events being unwilling to abate of her pretensions, attempted again to derive an augmentation of revenue, by levying duties on various articles which the colonists had been accustomed to import. Their resentment was again excited; and again it became necessary to attempt to allay it by receding. All the duties were accordingly repealed in 1770, excepting one of threepence a pound on tea, which, however unproductive, was still adequate to keep alive the deep-rooted jealousy of the people, and, if possible, by attracting their notice to its merely significant character, to augment their hatred of taxation.

Violent opposition.—The colonies now prohibited the importation of tea, in revenge of the impositions thus laid on it. Contentions soon afterwards arose between the residentiary governors and the provincial authorities; the soldiery, of course, taking part with the one, and the people with the other. A scuffle which occurred at Boston, on 5th March 1770, produced the first blood, several persons being shot, in consequence of an imprudent order to fire on the inhabitants. An assembly, held in Massachusetts, formally disowned the supremacy of the British government. Some arbitrary and inconsiderate measures, on the part of the legislature, exasperated the discontents, already too prevalent. In a word, every thing indicated the bursting forth of a flame which could only be subdued by the complete military inundation of the colonies, or their eternal separation from Britain. One of the first acts of aggression, on the part of the Americans, was the destruction of the Gaspee, an armed schooner belonging to his Majesty, which had been stationed at Providence, in Rhode-island, to prevent smuggling, the commander of which had given great offence by his vigilance in the performance of his duty. A reward offered for the discovery of the persons engaged in this affair was ineffectual. This took place in 1773. In the same year, some of the people of Boston, having entered into three ships which had arrived with cargoes of tea belonging to the East-India Company, now employed by the government in introducing that article, threw more than three hundred chests of it into the sea. Parliament, on being informed of this offensive proceeding, resolved on an exemplary punishment, and therefore passed a bill. "to discontinue the landing and discharging, lading and shipping, of goods, wares, and merchandize at the town of Boston, or within the harbour." This was followed by another bill, for "the better regulating the government in the province of Massachuset's bay," which had in view the abstraction of the executive power from the hands of the people, and placing it in the crown.

It was now impossible for the colonists to recede, without a sacrifice of all for which they had hitherto been so resolute to contend. Alarm, detestation, and revenge, spread universally. Assemblies were held in the different provinces, in which there prevailed but one spirit, though there were various opinions as to the most eligible mode of giving it effect. A general meeting of deputies was at last agreed on, for the purpose of concerting measures of defence and relief. These accordingly were appointed; and their first Congress, as it was called, met at Philadelphia on 26th October 1774.

Commencement of hostilities.—Their proceedings would have done honour to a much older assembly, and were very different from what might have been expected as the result of that untoward exasperation which had previously operated. But their petition to the king, and their address to the people of Britain, did not prove so efficient as their exhortations to their countrymen to persevere in determinations to defend their constitutional rights. It is unnecessary to specify the events which succeeded, till the commencement of regular hostilities in 1775. Generals Gage, Howe, Burgoyne, Clinton, and Cornwallis, were the officers first employed in the service of the mother country; and George Washington, who had formerly signalised himself in the British army which had defended the colonies against the French, was appointed commander-in-chief of the American forces. This illustrious man did not take the command till the month of July in this year. A battle had been previously fought at Bunker's Hill, in which the British, though they ultimately succeeded in carrying a fortification that had been the principal motive for the attack, lost considerably more men than their opponents. But the Americans had to regret the fall of their leader, Dr Warren, who had quitted the useful and highly honourable duties of the medical profession, to answer the more hazardous demands of his country.

The scattered troops of the provincialists were rallied, disciplined, and guided by Washington, who, after repeated skirmishes, obliged General Howe to abandon Boston, into which he himself entered in triumph in the month of March 1776. In the course of this summer, a powerful force, consisting of ships under Sir Peter Parker, and of troops under Clinton and Cornwallis, was repulsed with great loss in an attack on the capital of South Carolina. Some other advantages were gained in different places by the Americans; but they were greatly overbalanced by a series of disasters, viz. their defeat on Long-island—their being forced to abandon New York—their loss of Rhode-island—the discomfiture of their northern army—the capture of General Lee, one of their best officers, &c. in consequence of all which events this year might have been said to have almost utterly destroyed their hopes of independence. Desertion and sickness thinned the remaining troops, which it was nearly madness to suppose could prevail against the well disciplined, numerous, and high spirited enemy with whom they had to contend. But the intrepid and sagacious commander, in whose talents and successful influence all chance of redemption, humanly speaking, consisted, with not more than 3000 men, so far from yielding to useless despair, ventured to renew offensive operations. He made a sudden and totally unlooked for attack on his enemy at Trenton on the Delaware, routed them, taking above 900 prisoners; and soon afterwards bore down on three regiments at Princetown, over whom he obtained another complete victory. It was in July of this same year that the congress published their declaration of independence; so that, altogether, it must ever be memorable in the annals of the American struggle.

Colonists treaty with France.—The following year was distinguished by events scarcely less remarkable, most of which were in favour of the colonists; though the defeat of Washington at Brandywine, in consequence of which Philadelphia was captured, and his discomfiture not long after at Germantown, were mortifying checks to their rejoicing. But these and other inferior losses, could not prevent, though they might retard the accomplishment of their ambition. Besides, they were amply compensated by the surrender of the whole army under General Burgoyne on the 17th October, an event which not only afforded immense relief to their still confined means, but also, by its brilliancy, and the probability of its successful effects, laid a foundation for an important treaty with France. This was concluded on the 30th of January 1778, "by which," says an American writer often referred to, "we obtained a powerful and generous ally." But the operations of this year were not very considerable, and certainly no way decisive. Sir Henry Clinton, who succeeded to the command of the British army on the departure of General Howe for England, evacuated Philadelphia and retired to New York, in his march to which place he was exposed to serious losses by attacks on his rear.

In 1779 the Spaniards acceded to the American cause, and thus Britain found herself completely occupied. The campaign was various in its bearings on the ultimate question, but still appealed to future contests.

The year 1780 was more actively employed, and seemed at one period to threaten the ruin of American expectations. Charlestown, garrisoned by an army under General Lincoln, surrendered to the British troops commanded by Clinton and Cornwallis; this last officer completely routed General Gates at Camden, in the same province, and marched through the southern states without opposition; and the treachery of one of their own generals, Arnold, to whom, in his necessary absence, Washington had committed an important post, nearly occasioned the surrender of their finest army.

Colonists finally succeed.—The battle of Guilford, which took place on 15th March 1781, between General Green, who had succeeded Gates in the command of the southern department, and Lord Cornwallis, was most destructive to the British army, though the Americans were obliged to retire from the ground on which they had so desperately fought. Cornwallis having afterwards marched to Virginia, found it necessary to fortify himself in York-town, where, being blocked up by Washington, who had slowly followed him, he was under the necessity of surrendering on 19th October, which decided the contest in favour of America, and led to the treaty of peace, the preliminary articles of which were signed at Paris on the 30th November 1782, after an embittered and obstinate conflict of seven years duration, and an expenditure on the part of Britain of nearly an hundred millions of money, and the loss of about an hundred thousand lives.

Convention of the States.—The political constitution which had bound the states together during a season of danger common to the whole, was the hasty product of their apprehensions and necessities, sufficient, indeed, while these lasted, to give the energy of combination to their separate efforts, but quite unfit for their salutary government in the relaxation and carelessness of peace. Its defects were soon experienced to be numerous and essential. Discontents, jealousies, and insurrections very generally spread, and threatened a worse condition than would have occurred under the most despotic authority. These dissensions, at last, proved so detrimental to their interests, and especially their commerce, as to require a general convention, fully empowered to deliberate on the means of procuring tranquillity, and to recommend another form of government. The convention met at Philadelphia in May 1787, when Washington, the common benefactor of his country, was chosen president. Four months were passed in discussions and inquiries, which fully disclosed the prodigious evils already existing, and pointed out others near and formidable enough to occasion the most painful solicitude. A plan of federal government, seemingly adequate to the demands of the crisis, was agreed on, and measures were consequently taken to collect the sentiments of the people as to its adoption. It may be interesting to most readers to mention the result.

The small state of Delaware, after a few days consultation, ratified the constitution without a dissenting voice. Pensylvania displayed a very spirited opposition; but two-thirds agreed to the plan, and the dissentients gradually lost ground. New Jersey and Georgia were unanimous for the adoption. Connecticut had a small minority against the plan, which soon subsided. In Massachusetts the opposition was great and respectable, and five weeks were occupied in debates on the subject, when there appeared but a small majority for the constitution; to the honour, however, of the minority, be it mentioned, that on seeing the decision, they submitted with alacrity, and united

United States.

in support of the government. In New Hampshire the question remained a considerable time in suspense, occasioned, it seems, by some want of information; an adjournment was therefore made, and afterwards there appeared a respectable majority for the plan. Maryland was somewhat distracted by the arguments of certain able men, who opposed the measure, but it was eventually carried by five-sixths of the voices. South Carolina had two-thirds in favour of the proposition. Virginia carried it by a small number. New York exhibited an interesting scene, no less than two-thirds of the delegates being determined to reject the constitution; the debates were long and able, but as, during the session, the congress found itself empowered to organize the new government, the expediency of uniting with the rest of the states, and other reasons, induced the meeting, by a small majority, to accept of the plan. The case was different in North Carolina, which, for reasons not well known, rejected the constitution. Lastly, Rhode-island, by a perverse and singular policy, in place of calling a convention of delegates, as the other states had done, took the sense of the people in town-meetings, in which, on the whole, there appeared a majority against the plan. The public mind had been agitated in a remarkable manner; when nine of the states agreed the suspense was allayed, but considerable anxiety remained till Virginia and New York were known to have acceded. After this the general joy was excessive, and displayed itself in every method which ingenuity, gratitude, and hope, could devise to commemorate so propitious an event.

It is a circumstance not commonly known, that a federal representative government was planned by the American colonists so early as 1754, in a congress held at Albany. This, according to Governor Pownal, from whose "Memorial," (1803,) we learn the fact, was the first display of those "speculations in philosophy and inexperienced visions in politics," which ultimately occasioned the revolutionary state of Europe. However this may be, and undoubtedly it has a semblance of truth, it is still more certain that the conduct and fortune of the Americans had no mean influence on the disorganization of the French monarchy. But it is not to our purpose to do any thing more than merely hint at this interesting topic; and to some readers, perhaps, it may not be ill-timed to suggest, that there is a natural and almost invincible tendency in all colonies, whatever be its origin, to become independent of their parent stock. This, then, being admitted as physically or morally true, and as proceeding from causes which no political sagacity can obviate, it seems absurd to regret an event, which, essentially connected as it is with principles established in the method of providence for the government of the world, must be held, on the supposition of there being inherent goodness in that government, as necessarily productive of ultimate benefit. Whether the period has yet arrived at which the full amount of such profitable tendency could be realized, may certainly be doubted; but it appears not impossible to ascertain the existence of some advantages fairly imputable to the transactions we have been considering. It seems extremely probable, that the establishment of political freedom on the part of the American colonies, has proved more salutary to Britain than their continued and augmented dependency would have been. To give this probable supposition all the force of certainty, two facts, which are of no small moment, need only be referred to, namely, the prodigious extension of her commerce after that event, and the attainment of a power and resources, which, in defiance of greater hostile combinations than she had ever before encountered, and in the midst of convulsions that spared not a neighbour to congratulate her escape, preserved the sacred deposit of civil liberty and legitimate authority for the renovated world.

New Constitution.—The chief peculiarities of the new constitution thus adopted by the States may be summarily stated, and indeed require to be so for the due understanding of the nature of that singular government, to which, with all its imperfections, the Americans are indebted for their increasing consequence as a nation. The legislative power was vested in a congress, consisting of a senate and a house of representatives. The executive power was vested in a president, who, as well as a vice-president, was to hold his office for four years. The judicial power was vested in one supreme court, and such inferior courts as congress might appoint; the judges of the whole retaining their offices during their good behaviour, and receiving a compensation for their services without abatement, while continuing in office. Every state was to give full faith and credit to the public acts, records, and judicial proceedings of every other state, the congress being empowered by general laws, to prescribe the manner in which such acts, &c. should be proved. The congress, at the voice of two-thirds of the members of both houses, might propose alterations and amendments of the constitution or might call a general convention, for effecting such, if required to do so by the legislature of two-thirds of the several states; the decisions in either case being binding, when ratified by three-fourths of the members. The ratification of the convention by nine states was to be held sufficient for the establishment of the constitution between the states so ratifying. The members of the senate, or superior council, viz. two from each state, were to be chosen every six years; whereas, the house of representatives, which was not to contain more than 200 members, each of them representing from 33,000 to 50,000 inhabitants, was to be elected every second year. The president was to have the command of the army and navy, to make treaties with the consent of two-thirds of the senators, and to have the power of pardoning criminals, except in the case of impeachment. Sundry articles were occasionally added to the original draught of the constitution, and several objects are provided for and guarded against by specific regulations.

Political parties.—The first congress, according to the new constitution, met at New York in 1789. Its first measure was the highest expression of the general opinion of the supereminent services, talents, and influence, of the late Commander-in-chief, who, with a rare display of moderation, had resigned his power, and betaken himself to the enjoyment of

United States.

domestic repose, but who was now called upon, unanimously and urgently, to give dignity and firmness to the constitution, by accepting its most important trust. It is clear that there was no affectation in the reluctance with which Washington acquiesced in this honourable summons; and that he prepared, with self-denial and some painful feelings, to discharge the duties which such distinction enjoined. His arrival at New York was signalized by the most gratifying tributes of affection and confidence; and, for some time, his parental authority, sweetened as it was by the amiableness and simplicity of his personal deportment, allayed that party spirit, and those discordant emotions which had already disturbed the union. The chief feature of the political differences which now existed, and which have continued with little abatement to the present time, is recognised in the names of *Federalist* and *Anti-federalist*, so well known in the history of these states. Like many other terms commonly applied to political antagonists, these words do not accurately designate the ground of contention, and are liable to variation of meaning, according to the unavoidable changes of human affairs. In general, the former is understood to denote those persons who have a partiality towards a government of a monarchical nature, or at least one which, with some of the characteristics of monarchy, embraces the real, though perhaps not the nominal distinctions of an aristocracy; whereas the latter term is applied to those whose opinions are more congenial with the principles of a democracy, or a simple republic. Much of the remaining portion of the history of the United States is made up of the animosities and altercations of these two parties, and of the consequences with respect to other nations to which they gave rise.

Effects of the French Revolution on the American States.—Washington, though in sentiment a Federalist, was careful to avoid any display of his partiality, and actually chose a gentleman, Mr Jefferson, for the department of foreign affairs, who was admitted to be the head of the Anti-federalist opposition, but whose talents and character, in the judgment of that excellent man, were calculated to benefit his country. Such candour merited the cordial imitation of the controvertists. But the French revolution, by affording new and more powerfully stimulating fuel to their dissentions, ultimately defeated all attempts at reconciliation. The Anti-federalists appear to have greeted that event as a harbinger of the universal establishment of their sentiments, and endeavoured, by every measure which enthusiasm could suggest, to accelerate its triumph over antient politics. Their first effort was naturally enough directed against the remains of monarchical prejudices and practices in their own country; and accordingly, even the harmless and perhaps really necessary forms of the President's routine, were at last denounced as scandalous encroachments on liberty, calculated to wean men from it, and to introduce despotism, with all its trumpery, in its place. These sentiments were of course productive of suggestions for an alliance with France, now represented as the great restorer of the lost rights of mankind, and as destined to effect the emancipation of the world. The Federalists, on the other hand, without forgetting in any degree the former services of that nation, and having rather indeed the sympathy of gratitude towards it, were far from thinking that any circumstances warranted a departure from the strictest neutrality with the states of Europe, and, least of all, that any new conflict, or even a serious difference with Britain, could promote the welfare of America. Washington himself, who was re-elected to the presidentship in 1793, declared decidedly in favour of England, with which country a friendly treaty was formed in the following year, chiefly through his means. This certainly gave umbrage to the French Directory; but, by prudent management, hostilities were prevented. Mr Adams, who succeeded to the presidentship on the resignation of Washington, held similar sentiments and pursued a similar conduct.

War with Britain.—The elevation of Mr Jefferson to the head of the executive department in 1800, was followed, as might have been anticipated, by very different counsels, and a totally dissimilar policy, which continued with little if any abatement of hatred towards England, but with sundry modifications of malicious device, during the whole tremendous course of the revolutionary wars. We are far from thinking that there did not occasionally arise, on her part, some causes of offence, which might not in any common case have excited animosity if not hostilities between the nations. But these seem to have been almost inseparable from her critical condition, as the only remaining bulwark in Europe against a most intolerable tyranny, and would have been forgiven by any state that was not actuated by rancorous recollections, which prevented it from appreciating the value and probable consequences of the struggle. The forbearance of the Americans, under many provocations arising from the varied and arbitrary politics of France, must ever be placed in dishonourable contrast with that irritability and impatience which urged them to seek revenge in the multiplied calamities of an ancient friend. They had the merit, however, of selecting a period for their operations most likely to give satisfaction—when the whole resources of their antagonist were barely sufficient to afford a ray of hope to the overwhelmed empires of Europe. The war of 1812 found Britain engaged in a conflict on which the welfare of the human race depended; no wonder that she was somewhat slower in answering the challenge than became her former glory and her present unconquerable mind. By the events of the succeeding contest, she certainly did not enhance her naval or military reputation.

The Americans, on the contrary, were very fortunate by sea, especially at the outset, in which, however, they usually had the advantage of superior metal and fresher seamen; and though often defeated on land, had nevertheless the honour of at last successfully combating some of the choicest troops of their enemy. This war was prolonged, to the manifest injury of both countries, after the ostensible reasons which had occasioned it ceased to operate. But the restoration of peace to Europe, consequent on the first effectual coalition against Bonaparte, and his subjugation, accelerated its termination, which

United States.

West India Islands.

was brought about by the appointment of commissioners from each power assembled at Ghent in 1814. We hope, rather than believe, that peace was made in the "spirit of peace," and that a return of the advantages of commercial and friendly intercourse, will obliterate every ungenerous feeling between two nations, which must ever have greater cause for alliance than temptations to commit themselves to mutually destructive contentions.

Statistics.—The revenue of the United States, which, before the last war, was chiefly derived from the duties on imports and tonnage, had increased rapidly between the periods of 1791 and 1801, amounting, in the former year, to 3,329,750 dollars, and in the latter to 18,000,000. Of its amount between the last mentioned period and the commencement of the war in 1812, we have seen no satisfactory statement. In the course of the war it was found necessary to levy new taxes for defraying the increased expenditure, and these, in addition to the immense diminution of their commerce, must have produced a very general dislike to a contest with Britain. On an average of three years preceding 1805, it appears, from efficient returns laid before Congress, that the United States had imported annually from that kingdom and her dependencies to the value of more than eight millions sterling, while their exports to Britain and her colonies rarely exceeded five millions in each year; in the three years again ending after 1804, the average of exports to the United States was above twelve millions, and that of imports from them not more than four and a half millions. Some inference may be made from these premises of the advantages which Britain derived from her commercial transactions with that people.

A standing army being judged inconsistent with a republican government, the military strength of the United States is to be estimated from the militia, which was formerly reckoned by Dr Morse at 700,000, but on grounds not entitled to entire confidence. We should think the effective force not greater than the half of that number; but all calculations of the resources of the Americans are liable to perhaps greater errors than are usually experienced in the case of other nations. Their navy, in 1804, consisted of no more than twelve frigates from 36 to 44 guns, and some smaller craft; at the commencement, and during the continuance of the war, it was augmented with astonishing rapidity, both in number and magnitude, and is probably destined, in course of time, to assume a first-rate importance among the Atlantic fleets.

IV. West-India Islands.

The islands to which our attention is now to be directed, as connected with this quarter of the world, may be said, in general terms, to run in a south-east direction from the coast of Florida to the north-east part of South America, forming a sort of interrupted barrier to the gulf of Mexico and the Caribbean sea. In other words, they describe nearly the diagonal of a parallelogram, of which the sides are the 59° and 86° of W. Long. and the 10° and 20° of N. Lat. This diagonal, it is to be remarked, is of very variable breadth; and there are several smaller islands in different parts of the neighbouring coasts, which cannot be referred to it. In geography, we may notice, it is often convenient, for the assistance of the imagination and memory, to start a strong idea of the relations of places, though a very accurate examination might not require its precise adoption.

West India Islands.

These islands have received very different names, which have been applied to them either considered in one assemblage, or as subdivided into particular groupes, according to their geographical position, or some other principle of arrangement.

The common term, West Indies, not indeed strictly proper, is abundantly extensive in signification to comprehend all the islands of which we shall speak, without any regard to the discordant sentiments of different writers in the application of the minor designations, Antilles Great and Less, Windward and Leeward Islands. We commence from the north, merely glancing, in the first place, at a small cluster, not indeed immediately connected with the West Indies, but which may be more properly mentioned here than in any other part of our arrangement.

The islands now alluded to, named after the discoverer Bermudas, and sometimes Somers, (vulgarly Summer,) from the circumstance of the shipwreck of Sir George Somers in 1552, lie about 600 miles to the east of the coast of Carolina. They amount to some hundreds, but most of them are small and uninhabitable, and a reef of rocks and shoals by which they are surrounded renders access to them rather dangerous. In general, the climate is mild and healthy, but thunder and hurricanes are frequent, and the heat of summer is sometimes excessive. A soil, fertile enough in a few spots, produces Indian corn, roots, and fruits, in quantities sufficient for the inhabitants, and is occasionally adorned with trees, which are clothed with almost constant verdure. But the greatest part of the lands susceptible of cultivation still remains in a state of nature. The inhabitants, who are chiefly English, scarcely exceed 5000. St George-town, in the island of the same name, one of the largest in the cluster, is the capital. It contains about 500 houses, and is partially fortified. These islands belong to Great Britain, but can hardly be said to be of any value to that government. The chief employments of the people in these islands, besides the necessary care of the ground, are building vessels, for which they are well supplied with wood of the cedar species, and weaving sail-cloths.

The Bahama, or Lucayos Islands, lying at a short distance off the coast of East Florida, are very numerous, and occupy a large space. But many of them are mere rocks, and the greater part are totally unworthy of notice. The most important are *Eleuthera, Lucayo, Bahama, Yuma, Guanahani* or *St Salvador, and Providence.* In point of soil, they are said to be fertile, and in many respects to resemble South Carolina. Fruits are abundant, cotton and coffee are raised for exportation, and they are admirably situated for the purpose of trade. The population in 1803 was nearly 15,000, and is understood to be on the increase. Encouragement from

West India Islands.

the British government, to which they belong, may bring these islands to a state of great prosperity.

Cuba,—a valuable island, of great extent, being about 700 British miles long, and 70 broad, lies to the south-west of the Bahamas, from which it is separated by the bank and channel of Bahama. It is divided in the middle by a ridge of mountains running the whole extent of the island, and giving rise to several rivers or streams. These mountains are commonly covered with trees, among which are found ebony and mahogany; but towards the coast, the flat lands are in possession of a soil so fertile, that, with scarcely any cultivation, it perpetually abounds in almost every kind of vegetable riches. The chief productions are ginger, sugar, coffee, cocoa, tobacco, and cotton. In point of climate, this island is very fortunate, having scarcely any winter, and the heat of summer being much moderated by breezes from the sea. Certain districts, however, are reckoned unhealthy; but in great degree this is occasioned by the imperfect state of cultivation. The chief inconveniencies met with in Cuba are hurricanes and storms of thunder. In 1804 the population was said to exceed 400,000 souls, of whom a very considerable part was made up of slaves.

Few countries are so well furnished with bays and ports, or are so well situate for trade. But these and other advantages are far from having excited the enterprise and solicitous industry of the Spaniards, who seem to have hardly any other conception of wealth than as it exists in the state of gold and silver. Havannah, the principal town of Cuba, is built on the north coast, where there is a harbour of great extent and much security, but rather narrow of entrance. The town, which has somewhat of an European appearance, is fortified, and contains about 25,000 people. Puerto del Principe, Bayamo, St Jago, San Carlos, Holguin, and Guiza, are the names of other towns, none of which is near so large or important as Havannah.

Jamaica,—a fine island, lying about 100 miles to the south of Cuba, is the third in size in the whole of the West Indies, and is inferior only to Cuba and St Domingo. Its extreme length seems to be about 160 miles, and its breadth 60; but, according to some accounts, its length is only 120 miles, and its breadth 42, while others state the dimensions higher than above, and Mr Edwards makes the former 150, and the latter 40.

Traversed by mountains in different directions, but particularly from east to west, plentifully watered by an immensity of small rivers and streams issuing from the high lands, beautifully adorned with many species of trees, and enjoying a climate more temperate and agreeable than its geographical position would indicate, this island undoubtedly merits distinction as one of the best examples of a West Indian country. Its general appearance differs from most parts of Europe; and the north and south sides of the island differ also as widely from each other. An idea of this may possibly be conveyed by a few particulars selected from the description given by Mr Bryan Edwards, to whose History of the West Indies we must refer the reader for minuter information.

On the north shore, the country rises into hills more remarkable for beauty than for boldness, having a gentle acclivity, and being interspersed with vales and romantic scenery, but rarely broken abruptly or disfigured with craggy projections. The tops of the hills also are nicely rounded, and covered with groves of pimento, spontaneously sprung up, whose fine deep tints are charmingly enlivened by the verdure of the turf, seen in a thousand openings beneath. The effect is still farther heightened, and some agreeable emotions are excited, by the profusion of streams which pour from every valley, and which frequently project themselves from the overhanging rocks, as if in sportive joy, into the ocean. At a greater distance inland, and overtopping these picturesque appearances, the land rises towards the centre of the island, displaying a still greater profusion of wood, till the hills, at the extremity of the scene, becoming fainter and fainter, lose themselves in the clouds.

The character of the southern side, on the contrary, is that of grandeur and sublimity.—"When I first approached this side of the island by sea," says Mr Edwards, in his poetic language, "and beheld from afar such of the stupendous and soaring ridges of the Blue Mountains as the clouds here and there disclosed, the imagination (forming an indistinct, but awful idea of what was concealed, by what was thus partially displayed) was filled with admiration and wonder. Yet the sensation which I felt was allied rather to terror than delight. Though the prospect before me was in the highest degree magnificent, it seemed a scene of magnificent desolation. The abrupt precipice and inaccessible cliff had more the aspect of a chaos than a creation, or rather seemed to exhibit the effects of some dreadful convulsion which had laid nature in ruins. Appearances, however, improved as we approached; for amidst ten thousand bold features, too hard to be softened by culture, many a spot was soon discovered where the hand of industry had awakened life and fertility. With these pleasing intermixtures, the flowing line of the lower range of mountains, which now began to be visible, crowned with woods of majestic growth, combined to soften and relieve the rude solemnity of the loftier eminences; until at length the savannas at the bottom met the sight. These are vast plains, clothed chiefly with extensive cane-fields, displaying, in all the pride of cultivation, the verdure of spring blended with the exuberance of autumn, and they are bounded only by the ocean, on whose bosom a new and ever-moving picture strikes the eye; for innumerable vessels are discovered in various directions—some crowding into, and others bearing away from the bays and harbours, with which the coast is everywhere indented." We should err, however, if, from such descriptions, or any conclusions drawn from the position of this island, we conceived it to be peculiarly delightful as a place of residence. The violent torrents of rain at certain seasons; the frequency of storms, tempests, and hurricanes, and the prevalence of thunder and lightning for half the year, greatly diminish the comforts and security of the inhabitants. The nature of the vegetable productions raised in Jamaica will be readily understood from what has already

West India Islands.

been said of some other countries with which it agrees in situation. The chief difference is occasioned by the almost accidental peculiarities of the trade in which it is concerned. Thus Jamaica, at one period, yielded three-fourths of the coffee and one-half of the sugar produced by the whole of the British colonies; but these proportions have of course varied greatly, according to the demands of the market. The amount of the population, in 1787, was computed at 291,400, of which no less than 250,000 were slaves.

Kingston, the capital of Jamaica, is a thriving town, with 30,000 inhabitants, situate on the south side of the island, and on the north side of a harbour capable of holding 1000 ships. Some of the houses are well built, and its markets for butcher's meat, fish, fruits, and vegetables, are noted for their excellence. Its extensive commercial transactions render Kingston a place of very high consequence in the British transatlantic dominions. Spanish Town, or St Jago de la Vega, the seat of government, is a very agreeable town in the interior of the island, and 16 miles from Kingston, which it does not equal in size or importance of trade. Port-royal, opposite to Kingston, in the same bay, was once a flourishing place; but being visited in 1692 by an earthquake, which buried nine-tenths of the houses several feet under water; secondly, at the distance of ten years, almost entirely reduced to ashes by fire; and, lastly, on its third appearance, demolished by a hurricane, the people took alarm, and almost universally abandoned the spot as forbidden ground. The last calamity occurred in 1722, since which period, however, about 200 houses have been built on the same foundation, and probably, as its advantages in respect of harbour, &c. are great, it may recover some of its former consequence. Most of the other towns in this island are small.

St Domingo, Hispaniola, or Hayti—lies to the eastward of the two islands last described. It is reckoned from 350 to 400 miles long, in the direction of east and west, and from 100 to 140 broad from north to south, and is next to Cuba, in respect of size, among the West India islands. From Cuba it is separated by a channel, denominated by seamen the windward passage, which is about 36 miles wide. To both of these islands it bears considerable resemblance in general appearance, the nature of the climate, and the productions of the soil. Perhaps, on the whole, it surpasses them in the salubrity of the air, and in profusion of vegetation. The former, in a great degree, is to be imputed to the existence of fewer flat moist lands, and a more frequent alternation of hills and valleys; the latter is the natural consequence of superior richness, or greater depth of soil. Some places, however, are peculiarly unhealthy, owing to a great number of salt marshes.

Of the population, condition, resources, and productions of St Domingo, we can scarcely be said to have any very satisfactory accounts since the revolt of the negroes, and the consequent declaration and acquisition of their independence.

Porto Rico, an island belonging to the Spaniards, lies due east at a short distance from St Domingo, and is very nearly as large as Jamaica. In beauty of appearance, fertility of soil, abundance of streams, and temperateness of climate, it yields, perhaps, to none of the West India possessions; but, as usual, the policy of the European masters prevents any satisfactory disclosure of its true condition and produce. Among the articles enumerated in the statements of its value, it is usual to mention the mines of silver and gold on the north side of the hills by which it is divided in the direction of its length.

In 1778, the inhabitants were estimated at upwards of 80,000; but this, probably, was an exaggeration. Of its present population we have no conjecture. The capital, which bears the same name, is on the north part of the island, and is said to be a well-built town, having a good harbour.

Santa Cruz produces sugar, coffee, and cotton, has some good ports, and is well inhabited. *St Thomas*, not near so large, is proportionally as rich, and has an excellent harbour. *Tortola* is noted for a capacious road, where 1000 vessels may safely anchor.

The Caribbee, or Caribbean Islands, which are very considerable in number, and of material importance in a commercial point of view, extend in a sort of circular direction from the Virgin Islands towards the American coast, comprehending Barbadoes, which is more to the east than any of them, and Tobago, which is more to the south. *Anguilla*, or *Snake-Island*, so called from its shape, is a small flat island, tolerably fertile, and containing a few hundred inhabitants. *St Martin's*, a little to the south, is rocky, and not very productive, having but a thin soil, and no rivers. In some respects it resembles *St Bartholomi*, or *Bartholomew*, which, however, yields more sugar and tobacco. *Barbouda*, to the eastward of these two islands, is lofty in the middle, flat and low on the margins, affords good pasture for cattle, but is otherwise very sparingly productive, and being difficult of access from the encircling rocks and shoals, has been almost entirely neglected.

St Christopher's, or *St Kitt's*, is larger and more valuable than any of the islands just now named, is about 40 miles in circuit, produces sugar, tobacco, cotton, and fruits in great abundance, and has a population amounting to about 30,000 souls, of whom the majority are negroes. A good deal of this island is supposed unfit for cultivation, but the whole has a fine romantic appearance, and it possesses a healthy climate. Springs are abundant in the island, but commodious harbours and landing-places are wanting. North-west of St Christopher's are two small islands, *Saba* and *Eustatia*, both but indifferently productive, and also very defective as to ports. *Nevis*, separated by a narrow channel from St Christopher's on the south, presents the appearance of a single mountain, surrounded by a margin of low lands. The soil is not very rich, nor is there any harbour on the coast, but the island is well supplied with fresh water, and is inhabited by above 10,000 persons, by much the greater part of whom are negroes. Eustatia, St Christopher's, and Nevis, exhibit volcanic appearances.

Antigua, 60 miles south-east of St Christopher's, is about 50 miles in circuit, and contains nearly 60,000 acres of ground, the whole of which, with some trifling exception, is either employed in the growth of the sugar-cane, and other useful vegetables, or is of value for pasturage. In respect of good harbours, it is superior to most of the West-India islands. Its chief imperfection is the scarcity of fresh water; most of what is used is collected from the clouds, as the product of the streams and wells is in general brackish and disagreeable. The heat is often excessive, and destructive hurricanes are not unusual. In consequence of these causes, the crops of Antigua are uncertain, and often fail. Of the population of this island we have no very recent account: in 1774, the number of whites was 2590, and there were 37,808 slaves; the latter were estimated, in 1787, at 60,000.

Montserrat, a small oval-shaped island, about 20 miles to the south-west of Antigua, and about the same distance south of Nevis, is fruitful and pleasant, agreeably diversified with hills and vales, the former covered with a variety of trees, and the latter having the advantage of sufficient streams and a generous soil.

Guadaloupe, to the south of Antigua, consists, in fact, of two islands connected by a small arm of the sea, which is navigable for vessels of 50 tons. That portion to the east is called Grande-Terre, the other to the west Basseterre, the two together being above 200 miles in circumference. Grand-Terre is destitute of water, and possesses but an indifferent sandy soil; it is, therefore, but thinly inhabited, and poorly cultivated. The other division, which, from the circumstance of its first discovery, is often denominated peculiarly Guadaloupe, has abundance of water, a superior soil, and, from its number of hills and woods, displays some romantic scenery. Sugar, cocoa, coffee, and cotton, are the chief products of this island, which on the whole may be reckoned one of the most important of the West-India settlements. No wonder, then, that its cession by the British, who captured it from the French in 1810, to another power, conceived little entitled to such a boon, has been represented as an uncommon stretch of political generosity. Several small islands in its vicinity are considered as dependencies of Guadaloupe. Of these, *Maria-Galanta* and the *Isles des Saintes*, are of most consequence. Both have patches of good soil, are tolerably cultivated, and carry on some trade.

Dominica, about 20 miles south of Guadaloupe, is 29 miles in length, and 16 in breadth, presents a hilly appearance, and has but a small portion, comparatively speaking, of fertile land. It is, however, well watered, possesses a healthy climate, and has one of the largest and safest bays in the West-Indies. Its population is, perhaps, little short of 30,000 souls, two-thirds at least of which are slaves. The possession of this island, from its peculiar situation with respect to some of the French islands, was long an object of solicitude to the British government.

Martinico, one of the islands now alluded to, lies a little to the south-east of Dominica. It is about 135 miles in circuit, has an uneven irregular surface, the higher parts of which are covered with forests; is plentifully supplied with water, not always indeed of the best quality, and sometimes descending from the hills in rapid and destructive torrents; possesses considerable varieties of soil, from the most barren to the most liberal; and in point of climate, (were some of the masses of wood, which prevent the escape of moisture from the lands, removed,) could not be said to be unhealthy. The coast has many indentations, presenting safe and commodious anchorage. The conveniences of Martinico so much exceed its disadvantages, that the possession of it must necessarily be considered of very high consequence.

St Lucia, about 20 miles south of Martinico, is but a small island, unequally fertile, imperfectly cultivated, but capable of considerable improvement; has a diversified appearance, and possesses an excellent harbour. The population is probably little under 20,000.

St Vincent, still farther to the south, contains about 84,000 acres of land, well watered, but with a very unequal surface. The hills are mostly covered with woods, the valleys are in general of great fertility, but hitherto either nothing like the full extent of the requisite labour has been bestowed on the cultivation of the country, or a large portion of it is incapable of improvement. The British possess the most valuable parts, the others are still in the hands of the native Caribs.

Barbadoes, the most easterly of the West India islands, is 21 miles long and 14 broad, containing upwards of 100,000 acres of land, mostly cultivated. The soil being variable in nature as well as quality, admits diversity of product in considerable abundance; and the air is, on the whole, mild and healthy, not very subject to sudden changes of temperature, and little or not at all vitiated by moisture arising from marshy grounds. Though there be no river in the island, yet it is tolerably well supplied with water from many small springs, and, besides the rain in the wet season, by dews which are frequent during the night. In point of appearance Barbadoes is agreeable, having gentle risings, hills of easy ascent, and extensive plains, abounding in vegetation, which alternate or contrast with each other. Much of the coast is dangerous of access, from rocks and sand-banks, but there are some good harbours on the west side. Hurricanes, unfortunately, often interrupt the happiness of its inhabitants, and mar the products of their industry, besides exposing them to still more fatal effects. Thus the storm of October 1780 is said to have destroyed no less than 4000 persons. The number of inhabitants in 1786 was 16,167 whites, 838 free negroes, and 62,115 slaves.

To the south-west of Barbadoes are situate *Grenada* and the *Grenadines*. The former has a hilly irregular appearance, is well watered, has on the whole a good climate, and contains about 80,000 acres of land, the greater part of which is capable of cultivation. It has some good harbours, and is not much visited by hurricanes, at least such as are very ruinous. The population exceeds 20,000. Of the Grenadines, which form a chain in the direction of St Vincent towards the north, *Caricuacou* or *Cariacou*, *Redonda*, and *Bequica*, are the chief. They are small, and badly watered, but of tolerable fertility.

Tobago, the most southerly of the Caribbean islands, is about 30 miles long and nine broad, has a more temperate climate than is indicated by its situation, and is out of the tract of the hurricanes which so often threaten the total destruction of the other islands. The country has a very agreeable appearance; the soil is rich, springs of water are abundant, and the coast affords good shelter for vessels. Altogether, this island is highly favoured, and is a most eligible place of residence.

To Edward's History of the West Indies, Dr Pinkard's Notes on the West Indies, and Mackinnon's West Indies, we refer the reader for minute information respecting all or any of the islands now mentioned. Pinkerton's Geography, 3d edit. contains some useful extracts from these and other publications.

Trinidad, which is separated from the continent by the gulf of Paria, is reckoned about 90 miles long, and from 30 to 40 broad, and has on the whole a healthy climate and fertile soil, affording almost all the vegetable productions found on the American continent in its vicinity. There are several hills in the country, occupying about one-third of the whole surface, and much remains waste that is capable of being beneficially cultivated. Indian corn, great varieties of fruits and roots, tobacco and cotton, are among its most plentiful products. Earthquakes are sometimes experienced in this island, but hurricanes are unknown. The population of Trinidad was estimated some years ago at 17,749 souls, of which 10,000 are slaves. A lake of mineral pitch, subject occasionally to a kind of ebullition, and supposed to be of volcanic origin, is a peculiarly interesting phenomenon in this island.

Margaretta, lying off the coast of Cumana, is about 40 miles long and 18 broad, has no other water than what descends from the clouds, possesses rather a barren soil, and is inhabited chiefly by fishermen.

Blanca, *Tortuga*, *Orchilla*, *Bocca*, *Buen-aire*, and several other small islands which lie off the same coast and the Caraccas, do not admit of particular notice. *Curacoa* is about 36 miles long and 10 or 12 broad, covered with a thin layer of earth, capable, however, of culture, having some good harbours and a neat town of the same name, and carries on a tolerable trade, not by any means so extensive as formerly.

V. Discovery, Conquest, and Settlement of America.

The ancients were totally ignorant of this quarter of the world. A few obscure and dubious expressions found in their works, on which some enthusiastic admirers have descanted with undue confidence, partake more of the colouring of fancy than the solidity of actual observation. It is unlikely, we may say impossible, that without the aid of the magnetic needle so long a voyage should be performed; and the supposition is quite unsupported by any sort of testimony, that there formerly existed some intermediate country, such as islands, afterwards annihilated by a convulsion of the earth, which might serve as the means of communicating with the western continent. We must abandon conjectures, however plausible, when the object is to ascertain and do justice to the merits of a discovery so brilliant in itself, and so rich in consequences. It is equally incumbent on the historian to steel himself against extravagant pretensions, which have no other foundation than legendary reports and national vanity.

Dr Robertson has specified, with his usual perspicuity, the reasonings and opinions which led the illustrious Christopher Colon, or Columbus, to expect the discovery of new regions in the western ocean, or, at least, that, by holding on his course towards the west, he should arrive at some countries connected with the previously known continent of India. We have only to mention the consequences of this novel and arduous undertaking.

First voyage of Columbus.—Repeatedly and most vexatiously disappointed in his applications to some of the crowned heads of Europe, this man at last obtained the tardy and, indeed, puny encouragement of Isabella, one of the monarchs of Spain, to his projected operations. With the enthusiasm of a martyr, if not the caution of a philosopher, he set sail from Palos, in Andalusia, on August 3. 1492, with three small and indifferently constructed vessels, on a voyage unprecedented and universally condemned, which was to risk his fortune and his fame, and which, in the opinion of nearly the whole of the calculators of his time, even those, too, who gave their sanction to the enterprize, was much more likely to ruin both, than to obtain for him the honour of the most stupendous experiment yet performed in the science of geography. The incidents which occurred in this first voyage have been recorded with scrupulous, we may add, not unmerited devotion. On October 12. when the patience and confidence of his suffering companions were completely exhausted, and their indignation was wound up to a degree that threatened his life, Columbus had the delightful satisfaction of seeing a spot of land amid the immensity of the ocean which had so long appeared to baffle and to augment on his labours. It was the island of Guanahani, as the natives called it, one of the Bahamas, to which, however, Columbus gave the name of San Salvador, situated not less than 3000 miles to the west of Gomera, one of the Canary islands, where he had last touched in his perilous navigation.

The productions and appearance of this island by no means corresponded with the sanguine expectations of the Spaniards; but the possession of some small plates of gold, used as ornaments by the natives, gave rise to anxious inquiries for the place whence that precious metal had been obtained. The information procured on this point, and indeed his own peculiar views respecting his present situation, induced Columbus to direct his course towards the south. Besides some smaller islands which he fell in with in the course of this voyage, Cuba, named by him Juanna, and Hayti, which he called Espagnola, and on which he built a fort, were discovered. The state of his vessels, and the natural anxiety of his men, added to his own reasonable wishes to publish his discoveries to the world, now prompted him to return home. After encountering severe storms, which threatened the extinction of all his hopes, and having taken shelter, first in the Azores, or Western Isles, belonging to the crown of Portugal, and subsequently at Lisbon, he arrived at Palos on the 15th

Discovery of America.

March, after an absence of seven months and eleven days from the time of setting out on his voyage.

Second voyage.—The success of this expedition, it may very well be believed, brought so great a degree of credit to Columbus, that his suggestions for a second voyage were readily followed by preparations of a more extensive and encouraging nature. Not fewer than 17 vessels were immediately furnished with every requisite which his experience or opinion pointed out; and 1500 persons, some of whom belonged to the noblest families in Spain, were proud to embark with him. In this second voyage, commenced on September 25. 1493, some of the Caribbean islands were discovered. He did not return till 1496, much of his time being occupied in building a town in Hayti, arranging a government for that island, and in measures calculated to extend his discoveries, and direct them to beneficial purposes. In a third voyage, undertaken in 1498, Columbus, by sailing farther towards the south than he had formerly done, fell in with the island of Trinidad, and got sight of the mouth of the Oronoco. He afterwards surveyed the coasts of Paria and Cumana, the first parts of the continent that were discovered.

Last voyage of Columbus.—His last voyage, in 1502, carried him to another part of the continent, viz. the coast between cape Gracias a Dios and Portobello, which he surveyed. The fame of the discoveries made by this enterprising character roused a spirit of emulation throughout Europe. Voyages in search of unknown regions became an object of almost ordinary ambition, which was kept up by habit and the agency of many causes, long after there ceased to be any very high reward for the perils and privations which they occasioned.

Origin of the name of America.—One of the earliest of these expeditions deserves to be mentioned, not so much from the amount of the discoveries made, as from a circumstance which ultimately proved injurious to the just claims of Columbus. What we allude to is a voyage in 1499 under Ojeda, one of the officers who accompanied that navigator in his second enterprise. A person of the name of Amerigo Vespucci, a native of Florence, who seems to have acted the part of chief pilot in this expedition, on his return home published an account of the regions which he had visited. This being the first literary production respecting the New World, naturally enough had the effect of connecting his name with the subject of his writing; and accordingly, in a short time, the whole of the lands recently discovered, to which no peculiar designation had been appropriated, was currently denominated America. No fraud, or gratification of vanity, appears to have been intended by this man in giving rise to the title, which, however, in spite of repeated interference on the part of those who were anxious for the well-merited reputation of Columbus, has never been cancelled from the geographical vocabulary.

Of some of the chief voyages of discovery we shall now speak in order of time, but without occupying much room in the enumeration of circumstances.

Newfoundland and Labrador discovered.—John Cabot, a Venetian, but employed in the service of Henry VII. of England, who probably now regretted his not having listened to the application that had formerly, in an indirect manner, been made to him by Columbus, sailed from Bristol in 1497. By holding on a due west course, he fell in with the island which has ever since gone by the name affixed to it by his sailors, viz. Newfoundland. He afterwards coasted down the shore of North America as far as Virginia, when he returned home, successful in the main, as to important discovery, but disappointed as to the chief object for which he undertook the voyage, viz. to obtain a new and nearer passage to India. Corte Real, a Portuguese, anxious for a similar discovery, which formed indeed a prime concern in most of the expeditions of this period, got sight of the coast of Labrador in 1500.

Brazil discovered.—About the same period, another native of Portugal made a much more important discovery, and that, too, without any particular effort, unless to avoid the variable winds, which had so often been encountered on the coast of Africa by vessels going to India round the cape of Good Hope. Having for this purpose stood farther out to sea than was usual, he got sight of the coast of Brazil, on which he landed, and which has since proved so valuable an acquisition to his countrymen. The continent of America, therefore, it may be said, would have been discovered even without the sagacity of Columbus, though it is not unlikely that the Portuguese commander was encouraged to depart somewhat from the usual track of navigation by what he had understood of his previous success.

Further discoveries.—In 1501, Bastidas, a Spaniard, sailed along the coast of Terra Firma from cape Vela to the gulf of Darien. A similar voyage was performed soon after by Ojeda and Amerigo Vespucci, before spoken of. Juan Diaz de Solis and Pinzon discovered the province of Yucatan in 1508. A few years afterwards the former navigator sailed along the coast of South America as far as the Rio de la Plata. Previous to this, two considerable discoveries were made, that of Florida by Ponce de Leon, and the western coast of America, to the east of Panama, by Bilboa, who, with a small body of men, crossed the isthmus of Darien. He was the first European who reached the shores of the Pacific ocean. Bilboa is said to have waded into it, taking possession in the name of the Spanish monarch.

Mexico conquered.—In 1518, a small fleet, under Grijalva, sailing westwards along the north coast of Yucatan, discovered those lands in the gulf of Mexico which have since borne the name he assigned to them, New Spain. This led immediately to an armed expedition under Fernando Cortez, for the purpose of effecting the conquest of the country. The complete subjugation of the natives, and the establishment of the Spanish power, after a series of cruelty and injustice altogether unparalleled, were accomplished in 1521.

The Globe first sailed round.—About the same period, Magalhaens, a Portuguese, in the service of Spain, searching for a western passage to India, discovered the straits at the extremity of the southern continent which still bear his name, and which

Discovery of America.

eventually led to an extensive knowledge of the western coast. This voyage is peculiarly remarkable as the first circumnavigation of the globe, and of course the decisive proof of its general form.

Peru conquered.—Pizarro, in a vessel that sailed from Panama, on the west coast, visited the kingdom of Peru, of whose riches some fascinating reports had been previously received. His proceedings for its conquest began in 1530, and were not completed till after a period of 10 years.

French expedition.—In 1534, Francis I. fitted out a fleet at St Maloes for the purpose of making discoveries in North America. The command was given to James Cartier, who having first reached the coast of Newfoundland, sailed northwards till he reached the gulf and river called by him Saint Lawrence, after the saint whose name was attached to the day on which he made the discovery. In the following year he navigated that noble river for about 900 miles, giving the country the title of New France, in which he built a fort, and resided for the winter. Some efforts were made by the French a few years afterwards to colonize this country. A nobleman of the name of La Roche, obtained a grant of it from the king; but it was not till the commencement of the next century that their renewed efforts were crowned with success. See *The Natural and Civil History of the French Dominions in North and South America*, by Jefferys. Lond. 1760.

Mississippi discovered.—Ferdinand de Loto, a Spanish captain, having sailed from Cuba with a body of men intended for the conquest of Florida, landed in the bay of Spirito Santo, whence he marched in a north-west direction to about 35° on the banks of a river, where he died. His successor built some small vessels, in which he passed down the river till he entered the gulf of Mexico. Those transactions took place between 1539 and 1543. From several circumstances, it is very manifest that the river thus navigated was the Mississippi, now for the first time discovered.

Settlement in Florida.—Chatillon, admiral of France, early in the year 1562, equipped a fleet under the command of John Ribalt, destined for the American continent. It arrived on the coast of Florida on the 1st of May, from which circumstance he designated a river then discovered, May river, supposed to be the same that is now called St Mary's, and which forms part of the boundary of the United States. Coasting northwards, Ribalt discovered eight other rivers, to one of which he gave the name of Portroyal, and on another he built a fort, in which he left a colony, under the direction of captain Albert. This man's severity, however, occasioned his own death, and the ruin of the people committed to his care. In the month of June, two years after this event, Rene Laudonier, sent out also by Chatillon, anchored with three ships in May river, where he built a fort, to which, in honour of his sovereign, Charles IX., he gave the name of Carolina. In August of the same year Ribalt arrived at Florida a second time, having a fleet of seven vessels, intended for the service of the colony formerly left by him under Albert. He was pursued up the river where he had settled, by a Spanish fleet under Pedro Melandes, who, having obtained some advantages, barbarously put him to death, with his whole party. The tidings of this disaster reaching Laudonier, induced him and his comparatively feeble colony to escape to France, where, in the course of about three years after, a fleet was fitted out for the purpose of retaliating on the Spaniards who had so cruelly and unjustly possessed themselves of the country. This object was entrusted to Dominique de Gourges, and was most effectually accomplished, by the destruction of the fortresses which the Spaniards had erected, and the slaughter of very nearly all the men that defended them. Gourges, immediately after this gratification of revenge, returned home; and for about 50 years the French made no farther attempts to colonize Florida.

Expeditions of the English.—In 1576 captain Martin Frobisher, employed by England in making discoveries of a north-west passage to India, improved the geography of the North American coast, by the addition of several bays and islands. A strait to the north of Hudson's strait still retains his name. About three years afterwards, Sir Humphry Gilbert, in a voyage to Newfoundland, made some discoveries in that region, as St John's harbour, and the country to the south. He was lost on his return home. The voyage round the world, performed about the same period by Sir Francis Drake, had the effect of exciting a spirit of enterprise among his countrymen.

Sir Walter Raleigh's expedition.—In 1584 two patents were granted by queen Elizabeth, one to Sir Walter Raleigh, the other to Adrian Gilbert, for lands in North America not possessed by any Christian prince. Sir Walter fitted out two ships under the command of Philip Amidas and Arthur Barlow, who having anchored in a harbour about 20 miles west of the river Roanoke, on the coast of North Carolina, formally took possession of the country on 13th July, denominating it, in honour of their maiden queen, Virginia, an appellation soon bestowed on the whole of the English possessions in North America, but afterwards restricted to a state somewhat different from that to which it had been originally applied. A colony of more than 100 persons, left in this country by a fleet under Sir Richard Grenville, sent out by Raleigh in the following year, must have perished, had they not fortunately been visited by Sir Francis Drake, who carried them to England, after having made several conquests in the West Indies and other places. Grenville again arriving on the coast of Virginia, about a fortnight after the departure of Drake, though he knew nothing of the fate of the former colony, except that not a man of them was to be found, had the imprudence to leave at the same place a body of 50 men, none of whom remained in 1587, when governor White, sent out with a charter from Raleigh, arrived at Roanoke. Notwithstanding the fate of two former colonies, White ventured a third one; having, therefore, left 115 people at the old settlement, he returned to England. On August 13th of this year, it may be noted, Manteo, a native Indian, submitted to baptism in Virginia; he was the first who received that ordinance in this part of America; and on the 18th of the same month, a Mrs Dare was delivered of the first English child born in the country—it was a girl, to whom the name of Virginia was given. Equally unsuccessful, however, was this colony. The whole was either cut off by the natives, or perished from hunger, before the arrival of governor White with recruits in 1590. Farther efforts were abandoned. Here, then, it may be remarked as a very singular circumstance, that for more than a century after the discovery of North America, none of the European nations, with the exception of the Spaniards, had succeeded in an attempt to colonize it; and that, even so late as the period of queen Elizabeth's death in 1603, there was not one European family in all the immense regions between Florida and the coast of Greenland.

Virginia settled.—The foundation of the British dominions in this continent was laid in the reign of James I. This monarch, in the spring of 1606, by patent divided Virginia into two colonies: the *southern* or *first colony*, as it was called, and which comprehended all lands between 34° and 41°, was granted to the London Company; and the *northern*, or *second colony*, known also by the name of North Virginia, including the lands between 38° and 45°, to the Plymouth Company. These were associations formed, it would appear, at the recommendation of Hakluyt, a clergyman, to whom his country was indebted for much of her future glory as a mother of colonies. In order to prevent disputes between the two companies, it was expressly enacted, that they should not plant within a hundred miles of each other; yet with the greatest inconsistency, as is noted by Dr Morse, "the lands lying between the 38th and 41st degrees, are covered by both patents." The companies prosecuted their respective interests with zeal, but for some time with partial or inconsiderable benefit.

Progress of the London Company.—In 1606, the Earl of Northumberland's brother, in the service of this company, established a colony in Virginia, where he discovered the river Powhatan, or James river, as it is now called. On this river, in the following year, after the arrival of a new supply, a settlement was begun at a place named James town, which was the first town built by the English in North America. Captain Newport, who brought over the last recruits, having left Mr Edward Wingfield, president, with 104 persons, returned to England. In the winter of this year, James-town was burnt. By successive supplies, in 1608, and the following year, and after the company's council had obtained a new commission, the colony was increased to 500 men. It would have been greater if one of the vessels going out to it, had not been run ashore on the Bermuda islands, a circumstance that gave rise, as Sir George Somers was the commander, to their being called Somer Islands. The people who got on shore there having remained till they had built a sloop capable of transporting them, embarked for the colony, which, on their arrival they found had dwindled down to sixty persons, and these so miserable and dejected, that the whole resolved with one voice to return to England. On their way down the river with this intention, they were met by a new supply under Lord Delaware, who had recently received a patent, appointing him governor and captain-general of South Virginia. At his persuasion, they returned to James-town; and from this event, which happened in 1610, we may date the effectual settlement of Virginia.

Of the Plymouth Company.—The first vessel employed by the Plymouth company was captured by the Spaniards. Two vessels were next sent out in 1607, and arrived at a place some miles to the south of Sagadahok river, where a settlement was commenced. But most of the people being distressed by the severity of the winter, only forty-five men, with their president captain Popham, could be induced to remain after the month of December. They were doomed to encounter immense hardships, partly from the nature of the climate, and partly from the destruction of their storehouse, and most of their provisions, by fire; and, although they received several supplies from home, the colony broke up and returned to England in the following year, having lost their president Popham; and in consequence of their unfavourable reports, several years elapsed before any more attempts were made to settle North Virginia. At last, about the year 1620, Mr Robinson, leader of a religious sect, which had previously fled to Holland to avoid a persecution commenced against them in their own country, accompanied by his congregation, arrived at Plymouth, where the first effectual settlement was established. This country had already attained the title of New England from Captain Smith, who had been sent out to examine a gold and copper mine, or, in case of failure, to fish and trade with the natives. To his skilful representations and map of this part of America, much of the subsequent endeavours to colonize it must be imputed.

Canada settled.—Champlain, a Frenchman, began a settlement at Quebec in 1608, which, after various fortunes and contests, remained in the hands of his countrymen till 1763, when they were dispossessed by the British, to whom the whole of Canada has ever since belonged.

Dutch settlement.—In 1608 or 1609, Henry Hudson, an English navigator, discovered Long-island, attached to New York, and the river which still bears his name. He afterwards sold his claim or right to the country to the Dutch, who in 1614 built a fort on the west side of the river, near Albany, to which they gave the name of Fort Orange. This colony several times changed masters, the original possessors and the English being often at war, and with variable success. It remained at last with the latter, till the accomplishment of independence at the American revolution. Newfoundland was settled in 1610 by about forty planters, under John Guy, appointed governor by patent from king James.

Settlement of New Jersey.—New Jersey is supposed to have been settled much about the same time as New York, and partly at least by Dutch emigrants from that colony. To these were added, in 1627, a body of Swedes and Finns, who settled on the Delaware, and from whom many of the present families are descended. The whole territory was afterwards seized on by the English, to whom, after a re-conquest by the Dutch, it was conceded at the peace of Westminster 1674. In July of that year, it was divided into West Jersey and East Jersey by the duke of York, to whom his brother had formerly assigned the property. But the boundary line was never so accurately ascertained as to prevent contentions among the subordinate proprietors. These contentions, and various others, produced such confusion, that the proprietors in 1702 surrendered the government to the Crown.

New Hampshire settled.—New Hampshire, though discovered in 1614 by captain John Smith, of whom we have already spoken, was not settled till 1623, by a small party of English, near the river Piscataqua. In 1640, there were four distinct governments established on the branches of that river. These not agreeing as to a plan for general government, solicited the protection of Massachusetts, at this time become somewhat considerable. But in 1679 New Hampshire was erected into a distinct government; and a controversy afterwards arose between the two provinces about their boundaries, which continued for a long time, and required the interference of the crown. This province took an active part in the proceedings which terminated in the establishment of the United States.

Massachusetts.—Captain John Endicott, and a small company, began a plantation at Naumkeag, or Salem, in 1627. This company, which was soon afterwards joined by about 200 persons from England, under four clergymen, was the original of Massachusett's settlement. It was rapidly augmented by successive and immense supplies of new comers, notwithstanding the hardships to which the early planters were exposed. The rage, indeed, for emigration to New England in general became so great, that the King issued an order, in 1633, to prevent it, but without full effect. This spirit ceased however in 1640, when a change of affairs took place at home, which probably occupied the ambition of those who had more to hope for than to fear in any revolution. It has been calculated, that the number of persons who had gone over to New England before that event amounted to 21,200; whereas the number of those who have since left that country materially exceeds that of the new settlers. Nova Scotia, which had previously been joined with Massachusetts, was taken from it in 1713, and erected into a distinct government.

Maryland.—In 1633 Charles I. granted a tract of land on Chesapeake bay to Lord Baltimore, a Roman Catholic nobleman, who, with a number of his brethren that were persecuted for their religion in England, settled on it, and gave it the name of Maryland, in honour of the queen. This province encountered opposition from the government of Cromwell, which could not be established in it without bloodshed. Although the original settlers were Roman Catholics, and the province was really considered as an asylum for persons of that faith, the Protestant religion was established in it by law in 1692.

Connecticut.—Connecticut was granted by the Plymouth Company to the Earl of Warwick, in 1630; but three years elapsed before any English families settled in it. Great additions were afterwards made by conquest from the natives, with whom the settlers had many and long wars. In several respects the history of this province resembles that of Massachusetts, with which indeed it was intimately connected. In both, we may remark, the religious society commonly denominated Quakers makes a singular figure, both as agents and sufferers. Most of the citizens of Connecticut, attached by habit to a republican form of government, and much accustomed to the exercise of their own judgments in matters affecting their interests, were zealous in promoting the cause of American liberty.

Rhode Island.—The settlement of Rhode Island originated in religious persecution about 1635. Mr Roger Williams, a clergyman, and about twenty persons who concurred in opinion with him, were actually banished from Massachusetts as disturbers of the peace of the church and commonwealth established there, by a people who had themselves experienced similar treatment for a similar offence, if a difference of judgment on disputable, and often indeed inexplicable points, merit such an appellation. They settled at a place called Mooshawsick by the natives, who shewed them more humanity than their brethren. Mr Williams called it *Providence*, with commendable piety. For some time this small body suffered much from fatigue and want. It was afterwards joined by new exiles from Massachusetts, where a spirit of bigotry and intolerance prevailed. More extensive possessions were now obtained, partly through the influence of Sir Henry Vane, junior, and partly by successive purchases from the natives. A very liberal government was soon erected, which offered complete freedom to all religious persuasions, and by which, in a short time, the prosperity of the colony was effectually promoted. It has been remarked by Dr Morse, as an evidence of the independence of religion on civil authority in this province, that " no contract between a minister and a society (unless incorporated for that purpose) is of any force."

Carolinas.—In 1662, Charles II. granted to the Earl of Clarendon and seven others almost the whole of the territories of the three southern states, viz. the two Carolinas and Georgia; and, about two years afterwards, the boundaries were enlarged by a second charter. The proprietors, in virtue of the authority thus vested in them, engaged Mr Locke to frame a system of laws for their intended colonies. No effectual establishment, however, was made till 1669, when governor Sayle, with a company, settled on a neck of land between Ashley and Cooper rivers. It was not long before the settlers quarrelled among themselves; and the proprietary government being at last found inadequate, the parliament of Great Britain took the province under their immediate care, all the proprietors, excepting Lord Grenville, agreeing to accept of a sum of money for their property and jurisdiction. This agreement being ratified in 1729, the territory was divided into North and South Carolinas, which remained separate royal governments till the revolution.

Georgia.—The settlement of Georgia was not effected till 1732, when General Oglethorpe, in prosecution of a benevolent and wise policy, to relieve

Discovery of America.

some poor people of Great Britain and Ireland, arrived with 115 persons in the country, and built a town, which was distinguished by the Indian name of Savannah, from that of the contiguous river. The province itself was called Georgia, in honour of George II. who favoured the motives and plan for its settlement. Of the humanity that prompted to this undertaking it is impossible to doubt; but, unfortunately, the injudicious measures and regulations by which the proposed good was to be accomplished were soon felt by the first settlers, who, accordingly, and perhaps, too, it may be added, from an idleness of disposition not unusual in the class to which they belonged, were readily induced to forsake the colony and to seek better things in Carolina. It was now resolved, as the country appeared likely, if in good hands, to prove of importance to Britain, to engage a hardier and more industrious set of men in their place. Germany and the Highlands of Scotland were now looked to for the proper supply of colonists. The publication of the terms at Inverness, in Scotland, brought forward an hundred and thirty Highlanders, who were immediately engaged, and soon transported to Georgia, where, on the very confines of the British and Spanish territories, certainly with little propriety of selection, they built a town, to which they gave the patriotic name of New Inverness. Nearly at the same time, a hundred and seventy Germans were settled in another part of the province. To these, and the remains of the former settlers, were added many of their respective countrymen, so that the proprietors had sanguine hopes of rapid prosperity. In this they were completely disappointed; and, at last, such was the distressed state of the colony altogether, that it became necessary to surrender their charter to the king in 1752. Notwithstanding the various modifications which succeeded this event, the colony long continued unprofitable, and in a languishing condition. The peace of 1763 was the era of its prosperity, when, under the paternal administration of Governor Wright, it acquired commercial consequence and political stability. The war between Britain and her colonies was peculiarly injurious to the interests of Georgia for the time; but it was not long in recovering its relative importance, when the succeeding peace yielded new dignity to the United States.

Pensylvania.—The province of Pensylvania, so named from William Penn, its founder, was granted by Charles II. to that extraordinary character, in consideration of the services of his father, Admiral Penn, to whom the crown was largely indebted. In addition to the royal charter which was signed in 1681, Penn had the prudence to procure a quit-claim deed from the Duke of York, of all lands which, from their particular position, could possibly be supposed mutual or doubtfully adjusted. Penn himself accompanied the first colony in 1682; and having entered into pacific and friendly terms with the natives, succeeded in its establishment. He continued with it as governor till 1684, when a dispute with Lord Baltimore required his return to England. Though his address in inducing the settlers to agree to his original scheme of government prevailed, and his influence over them, as it deserved to be, was great, yet he was frequently thwarted in his proposals; and contentions between the people and the deputies whom he appointed in his place were neither unusual nor easy of adjustment. But, on the whole, although some symptoms of arbitrary proceedings on his part or that of his agents appeared, and various modifications were introduced, this province enjoyed a mild government, and speedily flourished. To this end the complete freedom of religious opinion, and the lightness of the public burdens, powerfully contributed. The old constitution was abolished at the revolution, and the proprietaries who were absent were excluded from all share in the newly erected government, though they still continued to possess many tracts of lands, and were besides offered L.130,000 in lieu of quit-rents, which they consented to accept.

Vermont, &c.—Vermont, lying north of Massachusetts, was settled by emigrants from other provinces in 1764, and became an independent state in 1777. Kentucky, discovered by James Macbride in 1754, was not settled till 1773, by Colonel Boon and his family. Its progress has been rapid almost beyond belief, and can scarcely be paralleled in history. The territory lying north-west of the Ohio, generally called the Western Territory, was settled by the Ohio and other companies, and erected into a separate temporary government by an ordinance of congress, in 1787. The country called Tenassee was first explored about 1745; but though two or three times attempted to be colonized, was not permanently settled till 1774. An immense wilderness divided the people of this state from those of Kentucky. North Carolina, which had for some time exercised the government of this territory, ceded it in 1789, on certain conditions, to the United States, and accordingly Congress made arrangements for its administration. It became an independent state in 1796.

VI. Of the original Population of America.

Population of America.

We can scarcely close this sketch, without adverting to a topic which long excited attention, and which is yet far from having ceased to interest the minds of speculative men. America, when discovered by Europeans, was not an unpeopled country. Besides several tribes of intelligent beings, in a state of nature, indeed, but unequivocally possessed of the characteristics of mankind, there were found in it two nations, at least, which had vindicated their claims to this distinction, by an advancement in several of the social arts, and the establishment of civil and religious government. The nations alluded to are the Peruvians, inhabiting part of the west coast of South America, and the Mexicans, on the peninsula which joins the two continents; to which it is not improper to add, the Muiscos, or Moscos, who were established in a portion of South America, now comprehended in New Granada, and the Natches, resident near the mouth of the Mississippi. The question was as urgent as it was natural, "Whence came these people?" "From what source, setting aside the invincible demands of their intelligence and attainments, have they derived their right to the honours of humanity?"

Obscurity of the subject.—In replying to this question, conjecture has been substituted for decisive facts, and, of course, the answers are as numerous and whimsical as the imaginations and reasonings of the authors who have treated of it. There seemed an apology for their various and discordant opinions in the circumstance of the newly discovered people themselves being totally unable to afford a particle of information on the subject. What inferences, then, could be deduced from the accidental, and perhaps aggravated resemblances which were observed between them and the people of other continents, especially such as concerned manners and customs, which could hardly have been copied and preserved with adequate fidelity, without, at the same time, some sort of traditionary documents respecting the nations whence they had been received? In many of the theories framed for the occasion, this singularity has been overlooked; and, on the contrary, a tedious, and often very faulty parallel has been attempted, which, though vastly more striking than has ever yet been demonstrated, would, in the absence of other facts, be totally incompetent to any satisfactory conclusions. Unless in the case of merely arbitrary institutions, which cannot be traced to some original principles of human nature, either left to itself or placed in like circumstances, it seems more rational to ascribe resemblances to causes of universal operation than to specific and restricted agencies.

Variety of theories.—We have many examples of the strange conceits to which the neglect of this obvious truth has given rise in the mode of discussing the topic now adverted to; and hence, in a great degree, it has happened, as is noticed by Dr Robertson, that "there is hardly any nation, from the north to the south pole, to which some antiquary, in the extravagance of conjecture, has not ascribed the honour of peopling America." We could not think of abusing the reader's time or patience by a detail of the different theories, to all of which it is possible to assign some serious, and, perhaps, insuperable objection. The historian just quoted was apprehensive he should offer an insult to the understanding of his readers, if he attempted either minutely to enumerate or to refute these theories. We agree with him on the inexpediency of refuting most of them; for the simple statement of their nature is sufficient proof of their absurdity. But, on the other hand, it is clear, that an enumeration, so far from being unnecessary, can scarcely fail to have a salutary effect in repressing the extravagant propensity of human genius, where there is no legitimate guide to controul its operations.

Connexion of the two hemispheres.—The first theory we shall mention supposes the former connexion of the eastern and western hemispheres; and, that previous to its being broken up by some convulsion of the earth, the inhabitants of America, derived in common course from the original pair of human beings, had been settled in their present abodes. Certain islands in the Atlantic ocean are conceived, by this theory, to be remains of the portion of land by which the connexion was established.

The Americans escaped the deluge.—Somewhat similar on the whole, though differing in important particulars, is another opinion, that the original inhabitants of this continent, derived also from Adam and his consort, found means to escape the deluge by which all the rest of mankind, with the exception of Noah and his family, perished. According to this theory, then, the native Americans are the most ancient people on the earth.

Distinct pairs of human beings.—It is the leading peculiarity in a third theory, that there were two creations of mankind, or two separate pairs employed in their production, and that the western hemisphere was allotted to one of these, as the eastern hemisphere was to the other. To the most of minds which support this system, it is of course easy to account for the vastly superior productiveness of the latter, as well as for their greater success in all the arts and institutions of life. They can readily imagine, for example, that the transatlantic couple did not begin to exist till a few centuries before they were discovered by their ancient prototypes. With no less facility it can be conjectured and proved, that there is a natural tendency in some soils to bring forth human beings; and that, therefore, neither America, nor any of the numerous islands of the South sea, lying at the distance of many hundred leagues from a continent, are indebted to an external cause for their population.

Contiguity of America and Asia.—Not quite so splendid is the theory, that as America and Asia are either united together towards the north pole, or are within a very inconsiderable distance of each other in the northern latitudes, so the inhabitants of the latter would find little or no difficulty in finding their way to the former by land, or in such coasting vessels as are in common use among savages. Of the vicinity of these continents there can be no doubt; and it is even probable that the distance, short as it is, was formerly shorter, since some of the islands lying in the vacant space, exhibit vestiges of a peninsular junction. A comparison, besides, between the people and animals found in the corresponding regions of these two continents, is asserted to yield force to the notion of such transportation. But it is not denied, that difficulties almost insurmountable present themselves in the way of the theory, especially respecting the people of South America, who cannot, by any ingenuity be made to assimilate to any of the tribes of North America, far less to any of the northern nations of Asia. This theory, after all, has many supporters, and certainly will never want a semblance of truth.

America peopled from Europe.—There is something almost equally plausible in the opinion, that Europe has supplied the western continent with its inhabitants. Accordingly, we are furnished by its advocates with accounts of Norwegians, Swedes, and Welsh, having early ventured over the intervening ocean, and planted colonies on the regions visited by them. These accounts, it is certain, would be quite satisfactory, provided they were true. But in the absence of certain evidence to this effect, every sensible reader, we presume, that is neither Norwegian, Swede, nor Welshman, will feel disposed to decline giving his sanction to the conclusion.

Population of America.

Very similar observations may be made on the claims feebly advanced in favour of some of the ancient maritime people that dwelt on the shores of the Mediterranean sea, as the Carthaginians and Phœnicians. Nor is there any unjustifiable scepticism in the rejection of certain superlatively absurd speculations by Adair, Endicot, Elliot, and others, which go to prove that the Jews are the primitive inhabitants of America.

Peopled from Africa.—Circumstances brought to light in the progress of navigation and geographical discovery, have led, in modern times, to the conjecture, that the southern continent of America might accidentally have received visitors from the opposite coast of Africa. It is demonstrable, that the trade winds, and the gulf stream as it is called, which is influenced by them, are quite adequate to the transmission of vessels across the Atlantic ocean; and we have already made mention of the unexpected discovery of the coast of Brazil, by a Portuguese fleet, destined for India by the Cape of Good Hope, and which had stood farther out to sea than was usual at that period. It is therefore quite credible, that imprudence, ignorance, or accident, might have occasioned perhaps more than once the involuntary and reluctant passage of the intermediate ocean to the puny navigators of the African coast. Nor would it at all be a valid objection to this opinion, that we have no records of the fact, nor any allusions in ancient writings to such an apparent loss of any individual expedition as might be rationally accounted for by the supposition adduced. The people, in fact, most likely to have been exposed to the adventure, those dwelling on the south-west parts of Africa, were too little known to have their operations related by foreigners, and too little advanced in civilization to have historians of their own. If, again, it be inquired, whether there are any examples of similar accidents having happened in other parts of the world, the answer is decidedly in favour of the theory. We are immediately referred to the history of some of the South sea islands. Thus, without going as far as Bougainville, who asserts the inhabitants of the Society isles to have made voyages of 300 leagues, we learn, beyond all contradiction, in the narrative of our own navigator Cook, to mention no other authority, that cases of canoes having been driven to very great distances from their destination are not uncommon in the traditionary reports prevalent among the people of those islands. The theory, then, rests on something more durable than arbitrary assumptions; and certain points of resemblance between a people recently discovered in Africa, and some of the natives of America, have given it a speciousness which is at least equal to the recommendations of any of the other theories proposed.

Peopled from all the old continents.—The last opinion of which we shall speak embraces all the facts which have been alluded to, and deduces from them the conclusion, that America has in reality been peopled from every one of the old continents, and that certain distinct peculiarities are sufficient to indicate their respective origins. Thus, the Esquimaux of the north, for example, are asserted to have affinity with the Asiatic Samoieds and European Laplanders; the Araucans, Peruvians, and perhaps we may add Mexicans, are conceived to derive their origin from Asia; and most of the savage tribes which peopled South America, are supposed to have proceeded from Africa in the manner already described.

Population of America.

Probable deductions.—On the whole, it seems obvious, that to restrict the probability of having peopled America to one of the old continents only, as Asia, for example, is very injudicious and unphilosophical. There is no necessity for narrowing the question in this manner, and, at all events, it is positively absurd to confound together the really distinct characteristics of the numerous natives found in America, unless we can point out satisfactorily, and by some sort of illustration, how, on the supposition of their identity of origin, such remarkable differences have taken place. Let us, at least, have one region for the parent of the North Americans, and another for the inhabitants of the southern continent, and let us prosecute inquiries into the appearances, the languages, the manners and sentiments of different people, till we discover, what is always entitled to weighty consideration, some peculiar and striking resemblance. This has been done to a certain extent already, but the premises are not yet of magnitude or consequence enough to justify decisive conclusions. The reader will see examples of it in Mr Pinkerton's Geography. Thus, we cannot help thinking the following remarks, with respect to the partial claims of Africa, deserve notice: " Copper-coloured tribes, with lank hair, have been discovered in Africa, but in no other quarter of the world; and it is well known, that this colour is esteemed peculiar to the American indigenes, while the southern Asiatics are tawny or olive."—" The numerous human sacrifices, and other cruelties of the American indigenes, strictly infer an African origin, no such practices being found among the Asiatic tribes." This statement, however, is to be received with qualifications, and in fact, as must be known to every reader, is not true. " The oblique eye of the eastern Asiatics, who, according to theory, ought to have peopled America, is no where to be traced on that continent." " The beard of the indigenes of America is thin and woolly, like that of the Africans; while that of the oriental Asiatics is thin, but strait and strong."—" The Natches of Florida say, that their ancestors came from the rising sun, or east; that the voyage was long, and the persons in danger of perishing, when they discovered America."—" The natives of the Canaries are said to have been extremely tall, and may perhaps have been the ancestors of the Tehuels, called by Europeans Patagons, who always bury their dead on the eastern shores, as looking towards the country of their ancestors."—" The initial sound *Mb*, as *Mbao*, so common in Paraguay, &c. seems only known to the African and American enunciation; and it also appears in the Coptic, which is asserted by the best judges to be a peculiar and indigenal idiom, and not a dialect of the Assyrian." Vol. II. p. 510. third edition. This author, we may add, appears to have bestowed much attention to

Population of America.

this difficult question, and to have come to the conviction which we have stated in the last theory enumerated.

Character of the native Americans.—We shall conclude with a very general description of the most remarkable peculiarities of the American tribes. The subject must already be made familiar to most readers, by the almost universally perused works of Robertson and other authors.

Size and form.—The native Americans, in general, do not differ in size from Europeans. The exceptions are the Esquimaux, on the one extremity, and the Patagonians on the other. They incline to be round, or of full body, and have therefore a plumper appearance than is commonly met with in the Old World. It is not certain whether this depends on peculiarity of constitution, or mere indolence of life in the possession of abundant nourishment. Both causes may contribute to the effect. That some influence may properly be ascribed to the former, is manifest from the circumstance of their thicker skins, as proved by anatomical examination. But it is not unlikely that even this peculiarity is the result of their mode of living, and the practice of covering their bodies with various oily and colouring substances.

Colour.—The usual complexion of the native Americans is a sort of pale brown, designated by the name of copper-colour, which prevails, with very inconsiderable exceptions, throughout the whole of the continent. Not a single negro was found in the New World at the time of its discovery by Europeans. This singularity of colour, and the absence of black men in latitudes corresponding with those in the Old World, where they prevail, must ever present a formidable obstacle to the opinions respecting the original population of America.

Hair.—A notion long existed that the Americans had no beards, and that their heads alone were covered with hair. This defect was ascribed to a debility of constitution, by which they were supposed to be rendered very inferior to the inhabitants of other countries, both in mind and body. But the observation was hasty. It is distinctly ascertained that they are not naturally defective in this appendage, but that it is a very common, almost an universal custom among them, to extract the hairs by the roots wherever they appear, with the exception of a tuft on the top of the head, which is regarded as an ornament. Their hair is usually thick and smooth, and seldom inclines to curl.

Features and expression.—In point of features, the Americans cannot be said to be handsome or elegant, according to European prepossessions. Their faces are round, their foreheads small, the extremities of their ears are far from the face, they have small eyes, generally of a black or chesnut colour, with flat noses and thick lips. An indication of mildness discoverable in their countenances at a distance, is unpleasantly contrasted with a jealous and somewhat sulky expression, which strikes a spectator on more close examination.

No deformities.—The rarity, or indeed complete absence of deformities and lamenesses among the Americans, so early noticed by their visitors, is accounted for on reasons very different from any superior healthiness of constitution, or the greater facility of parturition. The fact seems to be, that such children as are likely, from any defects or weaknesses, to prove burdensome to their parents, or unfit for their own preservation and the services of the tribe, are put to death soon after they are born.

Aged and useless destroyed.—It is on a similar principle that those of their number who have survived their strength, and the capability of joining in martial operations and the fatigues of the chace, are deprived of existence, by what is considered the pious interference of their nearest relatives.

Morality and Religion.—From such specimens, it is scarcely necessary to remark, we may safely infer the low state of civilization among the American tribes, though by no means the absence of all moral feeling and sentiment. We have, on the contrary, unequivocal evidence of their general belief in the existence of some being to whom they are responsible for their actions, and of a sense therefore of right and wrong, however erroneous may be their notions of virtue, or imperfect their obedience to its dictates. Marriage is instituted and respected among them, though females are not in esteem, and are subjected to almost intolerable slavery. Religious rites, of some sort or other, are almost universally practised, in order to avert calamities, or obtain favours. The belief of a state of immortality, when the present life is ended, is the solace of their sorrows, and promises the highest reward of their hardships and valour. But it is associated, as might be expected, with the grossest notions of happiness, and, still more unfortunately, is productive of a savageness of disposition, which cannot be satisfied without the most wanton torture of their unfortunate enemies.

When discovered, they were almost perpetually occupied in war, or the pursuit of wild animals, on which they were dependant for their subsistence. They had, consequently, little or no time to cultivate the arts of peace. A few manufactories, as of a kind of coarse cloth, matting, and baskets, were found among them. They were so far advanced, however, in taste, as to be fond of decorations, and had sensibility enough to be delighted with such music, poetry, and dancing as their ingenuity had invented. Their eloquence, when it came to be understood, was much extolled, because, in fact, being the energetic expression of simple but strong feelings, it was naturally sublime. Great changes, it is reasonable to imagine, have taken place among them since their intercourse with people much more improved than themselves. Their alliance has often been courted by European nations engaged in hostilities with each other, or anxious to obtain secure possession of their favoured regions. In these connexions, fidelity and treachery, bravery and cowardice, magnanimity and meanness, have been repeatedly and singularly combined. On the whole, they appear to have bee little benefited by the labours, whether political o r religious, of their European associates, for the advantages thence derived have almost invariably been accompanied by a participation in one destructive vice, that of drunkenness, which, without any other evil, is amply sufficient to degrade even the worst characteristics of savage life.

AMERICAN Night Shade, the name of some of the species of plants included under the genus Phytolacca.

American Ground Nut, a species of plant included under the genus Arachis.

AMERICUS Vespucius, the navigator whose name the vast continent of America now bears, although his visit was posterior to the time of its discovery by Columbus. See Vespucci.

AMETHYST, a coloured variety of rock-crystal. The colour, which is purple or red, of different shades, seems to depend on iron or manganese, or a mixture of both. See Mineralogy.

AMETHYSTEA, a genus of plants belonging to the class Diandria, and order Monogynia.

AMHAR, or Amhara, a district or province of Abyssinia, which is distinguished by being long the residence of the royal family and many of the nobility, and by the prevalence of a peculiar dialect, called the Amharic, which is adopted as the court language. This province is an elevated region, which includes the lofty mountain, or Ambageshen, the place of confinement of the younger branches of the royal family, to prevent their interference with the affairs of government. But although the Amharic dialect be regarded as the polite and fashionable language, all the books are written in the Ethiopic or Geez; and, by a traditionary law, destruction is denounced against any one who shall attempt to translate the Scriptures into any other language.

AMIANTHUS, a variety of asbestus, which is included under the magnesian genus of minerals; and from its fibrous structure, and flexible and incombustible property, it was employed by the ancients in the manufacture of their celebrated incombustible cloth. See Mineralogy.

AMICABLE Numbers, denote pairs of numbers, each of which is mutually equal to the sum of the aliquot parts of the other. This name was applied to such numbers by Schooten, although these numbers had been previously investigated by Rodolphus, Descartes, and others. The numbers 220 and 284 form the first or least pair of amicable numbers. Thus, the aliquot parts of 220 are 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110, and their sum is equal to 284; and the aliquot parts of 284 are, 1, 2, 4, 71, 142, and their sum is equal to 220. The second pair of amicable numbers are 17,296 and 18,416; and the third pair are, 9,363,584, and 9,437,056. See *Hutton's Mathematical Dictionary*, and *Leybourn's Mathematical Repository*.

AMID-AMID, a lofty ridge of mountains in Abyssinia, supposed by some to be a continuation or branch of the Mountains of the Moon of the ancients; but this is considered by others an erroneous opinion; and indeed it may be added, that no precise information of the Mountains of the Moon has yet been obtained. The ridge of Amid-Amid is particularly described by Mr Bruce.

AMIDA, an ancient city of Mesopotamia, situated on elevated ground on the river Tigris, and on the borders of Assyria, is now under the dominion of the Turks, and its modern name is Diarbekir.

AMIENS, formerly the capital of Picardy, and now of the department of the Somme, in France, is finely situated on the banks of a river, from which the department derives its name. Amiens was a place of considerable note in the time of the Romans, and was occasionally selected as the residence of some of the emperors. The Somme is navigable to Amiens, and three branches of that river traverse the city. The streets and squares are spacious, and many of the public buildings are distinguished by their elegance. The cathedral, with its beautiful paintings, fine pillars, and numerous chapels, is greatly admired as a magnificent Gothic structure. The population exceeds 40,000; and manufactures of linen, woollen, and soap, are established in the town. The definitive treaty of peace which was entered into by the different European powers was concluded at Amiens in 1802. Amiens is 90 miles N. from Paris, and 106 miles S. from Calais.

AMLWCH, a sea-port town in the island of Anglesea, in Wales, which, since the year 1768, has risen from a small fishing village to a town of 5000 inhabitants, owing to its immediate vicinity to the celebrated copper mines in Parys mountain. The harbour is an excavation of the solid rock, sufficiently capacious to admit thirty vessels of 200 tons burden each. It was dug out at the expence of the copper mining companies, for the exportation of the produce of their mines.

AM-KAS, a spacious saloon in the palace of the Great Mogul, where he appears, on solemn festivals, in all the richness and parade of oriental magnificence.

AMMANIA, a genus of plants belonging to the Tetrandria class, and order Monogynia.

AMMI, Bishop's Weed, a genus of plants belonging to the Pentandria class, and arranged with the natural order of *umbelliferous* plants.

AMMIANUS, Marcellinus, a Roman historian, was a native of Antioch in Greece; in early life entered into the military profession; and about the year 370, as an officer of horse, accompanied the emperor Constantius in some of his eastern expeditions. His history, which was composed at Rome, commences with the reign of Nerva, and is continued to the death of Valens, originally extended to thirty-one books, of which the first thirteen are lost, and is so distinguished for candour and impartiality, that the historian of the Decline and Fall of the Roman Empire pronounces the author to be "an accurate and faithful guide, who composed the history of his own times without indulging the prejudice and passions which usually affect the mind of a cotemporary." He died about the end of the fourth century.

AMMODYTES, or Sand-eel, a genus of fishes which appear in great shoals on many of the shores of Britain. See Ichthyology.

AMMON, or Hammon, the Jupiter of the Egyptians, by whom he was worshipped under the figure of a ram. Mythological history traces the origin of the name to Bacchus, whose army traversing the Assyrian desarts, and almost perishing for want of water, was relieved by Jupiter in the shape of a ram, who conducted them to a copious spring. In grateful remembrance of the kind interposition of his father, Bacchus erected a temple on the spot, and consecrated it to Jupiter-*Ammon*, from a Greek word which signifies *sand*, and is thus expressive of the scene of the event. But, according to annotators on Scripture, the Egyptian Ammon ought to be referred to Ham, the son of Noah, whose history seems blended and obscured with heathen mythology; for the Hebrew word Ham, and the Greek appellation of Jupiter, are derived from words of the same meaning, and which signify *to be hot or warm*. Egypt was called in Hebrew, *Mizraim*, supposed to be from Mizraim the son of Ham, and also *Chemia*, from Cham or Ham; from all which it is concluded that Egypt was peopled by the son or grandson of Noah, and that the nation, always inclined to idolatry, had instituted a system of worship to the founder of their race, under the name of Ammon, and from them the same religious system was extended to Greece.

AMMONIA, one of the three alkalis, properly so called, and, from its volatile nature, denominated *volatile alkali;* and in the older language of chemistry and pharmacy, *spirit of hartshorn*, and of *sal ammoniac*, names expressive of its origin; has been long known as a compound of hydrogen and azote, which the brilliant galvanic discoveries of Sir Humphry Davy have shewn to be in combination with a metallic base. See CHEMISTRY.

AMMONIAC, a gum resin which is extracted from a plant belonging to the genus *ferula*, one of the umbelliferous tribe, and derives its name from the temple of Jupiter-Ammon in Egypt, in the vicinity of which the plant grew spontaneously. The same plant is also a native of some parts of Persia. See MATERIA MEDICA.

AMMONIAC, *Sal*, a neutral salt, composed of ammonia and muriatic acid, and hence called *muriate of ammonia*, was originally obtained from the excrementitious matters of camels which were employed by those who visited the temple of Jupiter-Ammon in Egypt, and to this the name is ascribed, is extensively employed in various arts, which are now supplied with it from manufactories established in most parts of Europe. See SALTS.

AMMONITÆ, or AMMONITES, or *Cornu Ammonis*, a genus of univalve shells, which are always found in the petrified state, and generally in limestone or sandstone strata, and, like many other animal and vegetable petrifactions, have not been discovered in the recent state, from which it is concluded that the species are entirely lost.

AMMONITES, a people who inhabited Syria, and were descended from Ammon, the son of Lot. The history of this people, as it is recorded in Scripture, and by Josephus, notices their conquest of a gigantic race who dwelt in the mountainous regions of Gilead, and the occupation of their territory; the command of God to the Israelites, not to disturb the children of Ammon, or to make any encroachment on their possessions; their demand for the restitution of part of their territory, long held by the children of Israel, and taken from the Ammonites by Moses; their entire defeat by Jephtha; their hostile aggressions in the time of Saul and David, and their subjection to the kingdom of Israel; their attempts to throw off the yoke by an alliance with the Moabites, and repeated invasions of the kingdoms of Israel and Judah; their complete discomfiture and second subjection; their dispersion by Nebuchadnezzar, and restoration by Cyrus, after the destruction of Jerusalem by the Romans; their distinctive appellation lost in the more general denomination of Arabians; and, before the end of the third century, no trace of their name in existence, thus verifying the prophecy of Ezekiel, which declares, that they should "not be remembered among the nations." Deut. chap. ii. Judges, chap. ii., 2 Sam. chap. x. & xi., Ezek. chap. xxv., and Joseph Antiq.

AMMONIUS, surnamed SACCAS, a native of Alexandria, who flourished about the beginning of the third century, is celebrated as the founder of a popular system of philosophy, the object of which was to select from the prevailing systems, and especially from those of Plato and Aristotle, such tenets and doctrines only as commanded universal assent, and to reject all such as were obscured with doubt, or were susceptible of controversy. This system was distinguished by the name of Eclectic philosophy, from its accommodating and plausible nature, was at first very generally received, continued long to arrest attention and command approbation, and its author obtained the dignified designation of heaven-taught. But the attempt to reconcile the jarring opinions of the ancient philosophers, and to combine the maxims and morals of the heathens with the doctrines of Christianity, was too arduous to be followed with success, and the complying spirit of the system was ill calculated for the investigation of truth.

AMNESTY, an act by which offences against any government or state are declared to be annulled and forgotten. The word is derived from the name of an edict of a similar nature, which was published by Thrasybalus, after the expulsion of the tyrants from Athens.

AMNIOS, or AMNION, a thin pellucid membrane which forms the internal covering of the foetus in the womb.

AMNIOTIC ACID, a peculiar acid which is obtained in a concrete state by evaporating the *liquor amnii*, or waters of the amnios.

AMOMUM, or Ginger, a genus of plants belonging to the class Monandria, and order Monogynia.

AMONTONS, WILLIAM, an experimental philosopher, was born at Paris in 1663, and from his earliest years was afflicted with deafness, a calamity which, it is alleged on doubtful information, he did not regret, and even declined any attempts to alleviate or remove; for, while such a misfortune excluded him from one of the chief sources of social enjoyment, it enabled him at the same time to concentrate the powers of his mind, and to direct them with less distraction to geometrical and mechanical studies, which became his favourite pursuits, and can only be successfully prosecuted with vigorous thought and assiduous attention.

The discovery of the perpetual motion, that airy phantom of false philosophy, which has often occupied the minds of men in fruitless efforts of ingenuity, and even at the present day is sought for by some in powers of magnetic attraction and repulsion, was one of the first speculative investigations of Amontons; and he indulged the vain hope, that the aid to be derived from mathematical principles would enable him to accomplish it. But his labours were more usefully employed in furnishing plans for public works, and in superintending their execution, for which the practical applications of his mathematical knowledge supplied him with the necessary qualifications. The invention of the telegraph for promoting speedy intelligence, a discovery not unknown to the ancients, although the moderns are disposed to arrogate it to themselves, and the invention and improvement of various meteorological instruments, of which an account is detailed in his "Observations on Barometers, Thermometers, and Hygrometers," are also enumerated among his valuable researches; while the numerous memoirs on kindred subjects, which he contributed to the volumes of the Academy of Sciences, of which he was a member, farther attest the extent of his industry and ingenuity. He died in 1705.

AMORITES, a people of Syria, who were descended from the fourth son of Canaan, and who originally occupied the mountainous regions to the westward of the Dead sea, are described by the prophet Amos as a race of gigantic stature, and of great valour, under the bold comparison of being tall as the cedar and strong as the oak. The same name appears to be extended to the whole inhabitants of Canaan. The Amorites were formidable enemies of the Israelites in their journey to the promised land; and the refusal of their king, Sihon, to grant the request made by Moses, to permit his countrymen to pass through his territory, under an engagement that his subjects and their property should be secured from injury, was followed by the total discomfiture of his forces, and his own death in the conflict, and by the distribution of his possessions among the tribes of Judah, Reuben, and Gad. Numb. chap. 13. Joshua, chap. 5. Judges, chap. 11.

AMORPHA, False Indigo, a genus of plants belonging to the Diadelphia class.

AMORTIZATION, or AMORTISEMENT, is the act by which lands or tenements are alienated or transferred to a corporation, or are turned into mort-main.

AMOS, the fourth of the minor prophets, lived about 780 years before Christ, was cotemporary with Hosea, and in early life had been a herdsman at Tekoah, four leagues distant from Jerusalem. The prophetic remonstrances of Amos are directed against the idolatrous worship and wicked lives of the people of Israel and Judah; they distinctly foretel the calamitous captivity of the ten tribes, and expressly declare their future restoration under the Messiah. The language of this prophet abounds with illustrations drawn from the pastoral life, with the habits of which his early occupation rendered him familiar. Applying the words of St Paul, "rude in speech, yet not in knowledge," to Amos, Jerome pronounces the language of the prophet to be deficient in grandeur of thought and elegance of expression; while a modern commentator, Bishop Lowth, is of opinion, that in sublimity of sentiment, beauty of composition, and splendour of diction, he is inferior to none of the prophets.

AMPELIS, a genus of birds belonging to the order of Passeres, and of which one species, *Garrulus*, the chatterer, sometimes appears in the northern part of the island. See ORNITHOLOGY.

AMPHIBIA, the third class of animals in the Linnæan arrangement, includes reptiles, serpents, and cartilaginous fishes. Some of the animals comprehended under this class possess the peculiar power of supporting life sometimes on land and sometimes in water, as the frog and crocodile; and hence the name of the class, descriptive of this character, is derived. See ERPETOLOGY and OPHIOLOGY.

AMPHIBRACHYS, which signifies "short on both sides," is the name of a foot in Latin and Greek verse, which is composed of three syllables, of which the middle syllable is long, and the first and the last are short, as *ămārĕ*, *ăbīrĕ*.

AMPHICTYONS, the deputies of the chief states of Greece, who formed a general council, to which were entrusted the regulation and superintendence of all the civil and religious affairs of the country. The original institution of this assembly is variously traced, to Amphictyon the son of Deucalion; to Acrisius king of the Argives; to a convention of the neighbouring states, which met at a very early period of the Grecian history at Delphi; and to the Hellenes, who were the founders of the oracle at Dodona, and the supposed authors of the more celebrated Delphian establishment. This assembly, which first met at Thermopylæ, but generally at Delphi, consisted of 30 members in the time of Antoninus Pius; but the number of deputies seems to have varied from ten to twelve, as the number of states admitted into the alliance was greater or smaller. Two deputies, it is said, were sent from each state; one of whom, elected by lot, was charged with the care of all matters connected with sacrifices and religious ceremonies; the other, chosen by the majority of the citizens, seems to have been employed in a judicial capacity, to hear and decide causes between private persons; but both were invested with the power of deliberating on the general interests of Greece.

A solemn oath, sanctioned by the most dreadful imprecations on those who should be guilty of its violation, was administered to the members on their admission; and the commencement of their deliberations was preceded by the sacrifice of an ox, which was cut into small pieces, as a symbolical expression of their union. The spring and autumn were the stated times for the meeting of the assembly of the Amphictyons; but on extraordinary occasions they were summoned at any time; and occasionally, when the affairs of the country required it, their deliberations were permanent throughout the year.

AMPHIMACER, a metrical foot in Latin poetry, composed of three syllables, of which the middle syllable is short, and the first and the last are long, as *cāstĭtās*.

AMPHION, who is represented in the fabulous history of Greece as the son of Jupiter and Antiope, the daughter of a king of Bœotia, and celebrated for his eloquence and skill in music, is supposed to have been a prince or ruler of Thebes, and having contributed greatly to the civilization and improvement of his countrymen, by the wisdom of his political institutions and the prudence of his government, is described in the fictions of the poets as moving the rocks, and arranging the stones into regular order to form the walls of the city. The same fiction has furnished a beautiful ornament to succeeding poets, and the art of Amphion is a synonymous expression with the art of music.

AMPHION is another character in ancient mythology, who was the son of Jasus, king of Orchomenos, and, according to Ovid, was the husband of Niobe, the daughter of Tantalus. Seven sons, and an equal number of daughters, the offspring of this marriage, rendered Niobe vain of her numerous family, and tempted her to treat with derision and contempt Latona, the mother of Apollo and Diana, because she had only two children. The affront and insolence with which their mother was treated were resented by the god and goddess, who in revenge slew the children with their arrows. The male children were destroyed by Apollo, and the female by Diana. Niobe herself, struck dumb with grief and despair, appeared like a senseless statue, and no doubt gave origin to the poetical fiction of her transformation into stone. This interesting story is beautifully related in the sixth book of the Metamorphoses of Ovid. The statue of Niobe, which is still admired as one of the most extraordinary specimens of ancient sculpture, is ascribed to the celebrated Grecian artist Praxiteles, in an epigram written in Greek by an unknown author, of which the following is a translation:

> While for my children's fate I vainly mourn'd,
> The angry gods to massy stone me turn'd;
> Praxiteles a nobler feat has done,
> He made me live again from being stone.

AMPHISBÆNA, a genus of serpents, which has this denomination because the species of which it is composed have the power of moving forward either with the head or tail. See OPHIOLOGY.

AMPHISCII, a name which is applied by geographers to the inhabitants of the torrid zone, because, as the name denotes, their shadow is towards the north during one part of the year, and towards the south during another.

AMPHITHEATRE, a spacious edifice erected in the latter ages of the Roman republic for the exhibition of public spectacles. Amphitheatres were originally constructed of wood; but about the time of Augustus, when they began to approach to that extent and magnificence which they afterwards attained, the more substantial and durable material of stone was employed. The largest structure of this description, and which became the model of similar buildings throughout the Roman provinces, was the amphitheatre at Rome, which was begun by Vespasian and completed by Titus, and has been distinguished by the name of *Coliseum*, the remains of which still exist, and exhibit one of the most sublime and perfect specimens of ancient architecture.

The Coliseum is of an oval form; the longest diameter is about 615 feet, and the shortest about 510. The arena, or middle space, on which the spectacles were exhibited, is about 284 feet in length, and 176 feet in breadth. The surface covered by the whole structure is not less than $5\frac{1}{2}$ acres. The building consists of three stories, the first about 33 feet in height, the second about 39, the third about 38 feet, and the pilastrade, which incloses the whole, is about 46 feet. The entire height, including the blocking course and the steps, is about 164 feet. Arched passages were constructed for the accommodation of the spectators. Four of these entrances were more spacious than the rest; two of which were reserved for the emperor, the senate, and other distinguished personages, and the other two were destined for the gladiators and animals which were to be exhibited on the arena. This magnificent and immense structure, which was capable of admitting 80,000 spectators, and, according to some accounts, more than 100,000, it is said, was completed in the short period of two years and nine months; and, if this be true, it is impossible to conceive a more remarkable instance of the wealth and resources of the Roman people.

The middle space of the amphitheatre, called the arena, because it was strewed with sand, was destined for the combats of gladiators and other spectacles. Surrounding this space were the cells for the wild beasts. Above the lodges or cells, a gallery was constructed, which was appropriated to the senators and other persons of distinction; and one part of the gallery, on which was erected a throne, surmounted by a canopy, and richly decorated, was reserved for the emperor. The other parts of the edifice were occupied by the people, according to their rank; and as the seats or benches, some of which were covered with wood, and others with cushions, rose gradually from the circuit of the arena to the top of the building, every individual of the assembled multitude saw distinctly the spectacles exhibited. The amphitheatre was open to the sky; but to protect the spectators from the sun and rain, an awning or curtain was occasionally employed.

It is not less to be regretted than wondered at, that Michael Angelo, one of the most celebrated artists of his age, should have aided the ravages of time in the destruction of the Coliseum, by removing great part of the outer-wall to procure stones for the construction of the Farnesian palace. With a more liberal spirit, Pope Benedict XIV. consecrated those venerable remains of antiquity, and erected a number of altars within the ruins, which thus became objects of pious respect; and still more effectually to secure them from future dilapidation, a hermit, whose cell occupied a small structure in the middle of the pile, was appointed to watch over the building.

Similar buildings were erected in other parts of the Roman empire, as in Jerusalem and in Cesarea, at Verona, Pola in Istria, and at Nismes in France. The amphitheatre at Verona consisted of three stories, and was 90 feet in height, covering a surface of more than four acres; no cement was employed in this building; the stones were united with iron cramps, which were covered with lead, to prevent the corrosion of the iron. Amphitheatres were sometimes constructed on the declivity of hills, by forming benches of stone or turf, and completing the oval form by works of stone at the extremities. Traces of an amphitheatre, in which the benches were of turf, have been discovered in the vicinity of Sandwich, in Kent; and similar temporary struc-

Amphora. tures, it is probable, were erected near camps and military stations in the distant provinces.

The first combats of gladiators which are recorded by historians, were exhibited in Rome, in the 490th year of the city, by the sons of Brutus, at the celebration of their father's funeral. Twelve years afterwards, the introduction of wild beasts, which afterwards formed a considerable part of these spectacles, took place, when the elephants, which were taken from the Carthaginians in Sicily, were exhibited by Lucius Metellus. The strong desire which the Romans expressed for these barbarous amusements, and the high gratification which they seem to have afforded, induced those who courted popular favour to expend enormous sums, with the view of surpassing their rivals or competitors in the splendour and magnificence of the exhibitions. The circus, a temporary structure, in which such spectacles were first exhibited, was neither convenient nor safe for the spectators. The inconvenience of seeing, which was experienced in the circus and succeeding temporary structures, the accidents which sometimes happened, when they were not of sufficient strength, and the danger to the spectators from the infuriated wild animals, finally led to the design of erecting amphitheatres of a commodious, safe, and durable construction, when those barbarous exhibitions, the delight of the Roman people, reached their highest perfection. At the opening or dedication of the Flavian amphitheatre, or Coliseum, 5000 wild beasts, according to the account of one historian, but according to another 9000, were destroyed. When the combats of these ferocious animals were concluded, the arena was instantly filled with water, presenting the appearance of a lake, into which aquatic animals were introduced to attack and destroy each other; these scenes were succeeded by a number of vessels, which represented a naval engagement. The triumph of Trajan over the Dacians was celebrated by the exhibition of every variety of these spectacles, which continued for four months, and in which a thousand gladiators were engaged, and 11,000 animals were doomed to destruction. Slaves, malefactors, and captives taken in war, were originally condemned to the horrid occupation of gladiators. Professional persons were afterwards trained and devoted to this service; and sometimes men of rank, and even, it is said, women, desirous of signalizing themselves in these bloody conflicts, entered the lists. In the beginning of the fifth century of the Christian era, the combats of gladiators were suppressed in the Roman empire; but the combats of wild beasts were permitted nearly a hundred years longer. In the middle ages, when chivalry flourished, the amphitheatre was chosen for the exhibition of judicial combats, tilts, and tournaments. Since the neglect and abolition of these rude amusements, the inventive genius of man has discovered no use for these huge buildings.

AMPHORA, a measure of capacity used by the Greeks and Romans. The Roman amphora for liquids was nearly equal to seven gallons and one pint English measure; the Grecian amphora contained a third more. The same name was applied to a dry measure among the Romans, the capacity of which was equal to about three bushels.

Amsterdam.

AMPLIFICATION is applied, by rhetorical writers, to that part of an oration or discourse in which the circumstances which accompany any event are enlarged upon, or minutely detailed, for the purpose of exciting strong emotions in auditors or readers.

AMPLITUDE is a term employed by astronomers to denote an arch of the horizon, intercepted between the east or west point, and the centre of the sun, or a planet at rising or setting.

AMSTERDAM, the chief city of Holland, stands at the confluence of the river Amstel with a branch of the Zuyder sea. In the beginning of the 13th century, a few huts, the miserable abode of poor fishermen, were all that occupied the place of this city, which its favourable situation for commercial enterprize, and the industry and activity of the inhabitants, have raised to the first rank for wealth and population. But in its progress to this pre-eminence it has not escaped various severe disasters. In the early period of its history it was frequently exposed to the attacks of its neighbours, against whose incursions it was surrounded with a brick wall in 1490; soon after it was nearly reduced to ashes by an accidental fire; in 1525, John of Leyden, the pretended king of Munster, headed a party of fanatics who had nearly possessed themselves of the city, but by the vigorous resistance of the inhabitants were overpowered, and almost the whole, to the amount of 600 men, were put death; ten years only had elapsed when another tumult, excited by the Anabaptists, whose object was to seize the government, disturbed the quiet of Amsterdam; but their frantic scheme, masked by religion, was defeated by the successful opposition of the citizens, and the fanatical insurgents were cruelly massacred; and as this city was one of the last which joined the confederacy, and embraced the reformed religion, an express stipulation for the free exercise of the Roman Catholic religion, in the conditions of surrender to the Hollanders after a siege of ten months, was most shamefully violated, and the unpardonable zeal of the Protestants burst forth and led to the expulsion of the monks, nuns, and priests, and the destruction of the emblems and altars of their worship.

Enlarged at different periods with its growing commerce and population, Amstersdam acquired, in 1675, twice its former extent, was surrounded with a wall and ditch, the latter eighty feet broad, and filled with water, and now covers a semicircular space more than nine miles in compass. A single gate forms the communication towards the shore, and eight towards the land side, all of which are massy buildings constructed of stone. Almost the whole of the city is built on piles of wood, which were required as a substitute for a solid foundation in marshy ground. The space which it occupies is traversed by numerous canals, and not fewer than 300 bridges facilitate the access to the different quarters of the city. The new bridge over the Amstel is a magnificent structure, consisting of 36 arches, some of which are very lofty, is 600 feet in length, and 70 in breadth, and affords a striking view of the sea, the harbour, Amsterdam. and the city itself. The streets of Amsterdam are in general narrow; but some of them, along the banks of the principal canals, can boast of the spacious breadth of 140 feet. Many of the private houses of the rich merchants are splendid edifices, furnished and embellished in the French style.

The stadthouse, which is always regarded as one of the most extraordinary buildings in the world, was begun in 1648, and in little more than eight years was completed at the enormous expence of two millions sterling, stands on 14,000 massy piles of wood, and is 282 feet in front, 255 in depth, and 116 feet in height. The external decorations of this building are bronze figures of Justice, Wealth, and Strength, with a colossal Atlas supporting the world, and some other statues; and it is surmounted by a tower 50 feet high, which is furnished with an excellent chime of bells, some of which are of large size. The internal ornaments of the spacious halls, and other apartments, are distinguished by their splendour and magnificence. The stadthouse is chiefly destined to the accommodation of the courts of justice, the public offices, and the municipal authorities. The prison occupies one of the courts of this edifice; and the apartments for the bank on the ground floor, it is said, contained 40,000,000l. sterling in bullion before the subjugation of Holland to France, during the revolutionary war. The admiralty, the arsenal, and the exchange, are also extensive and magnificent edifices.

The rasphouse is an establishment in which offenders are confined, and condemned to saw logs of wood, or to rasp Brazil and other dye woods; and those who are indolent or refractory are shut up in a cellar to which water is gradually admitted, and to save themselves from drowning they are obliged to work at the pump. The spin-house, or work-house, is a charitable establishment, as well as a place of punishment for petty offenders of the female sex. They are employed in sewing, and spinning wool, flax, and hemp. The numerous hospitals, and other charitable institutions, are supported partly by voluntary contributions, and partly by taxes on public amusements.

In the academy denominated the *Illustrious School*, the languages, philosophy, and divinity, are taught; and several respectable literary societies have flourished in Amsterdam.

Of the numerous churches, eleven belong to the Calvinistic or established form of religion, twenty-seven chapels are appropriated to the Roman Catholics, and two synagogues are destined to the Jewish worship, one of which is the largest in Europe. The new church, dedicated to St Catherine, is a magnificent building. The pulpit is greatly admired for its sculpture, the windows are adorned with paintings, and the organ is esteemed one of the finest in the world.

The civil administration of Amsterdam is intrusted to a senate or council of thirty-six members, who are chosen for life. The deputies sent to the states of Holland are elected by the senate, and by them are appointed the chief magistrates or burgomasters, who are twelve in number. From these, four are chosen to execute the duties of the office.

The trade of Amsterdam, before it experienced the severe checks during the French revolution, was prodigious. Its commerce extended to almost every part of the world, and it merited the appropriate title of the *storehouse of Europe*. The population, in 1806, was estimated at nearly 300,000. Amsterdam is 130 miles distant from Brussels, 150 from Liege, and 330 from Paris. N. Lat. 52° 22'. E. Long. 4° 45'.

AMSTERDAM, an island in the South Pacific ocean, discovered by Tasman, a Dutch navigator, and afterwards visited by Captain Cook; is 20 miles in length, and about 13 in breadth; is surrounded, like most of the islands in that region, with a coral reef; rises, even in its most elevated parts, but a few yards above the level of the sea; and the whole surface is laid out in plantations, which produce all the rich fruits of tropical countries. Yams, some other eatable roots, and sugar canes, were not uncommon. The natives appeared a brisk and lively race, with regular features, black hair, and fine eyes. The dress of both sexes consists of a piece of cloth, or matting, wrapped round the middle, and tattowing, or puncturing the skin is a prevalent practice. Cloth of various colours, and matting, of a finer fabric for dress and coarser for sails to their canoes, are manufactured. Their fishing implements resemble those of the other South Sea islands, and some of their smaller ornaments and domestic utensils are neatly executed. S. Lat. 25° 11'. W. Long. 173°. The same island is known by the native name of Tongataboo.

AMSTERDAM, an island in the Indian ocean, which was visited by some of the attendants of the embassy to China in 1793, is about four miles long and two miles broad, and is inaccessible except on the east side, where a tolerable harbour, with eight or ten fathoms depth of water, seems to have been formed from a volcanic crater. The soil, which is soft and spongy in most parts of the island, and in some places so hot as to prevent vegetation, the springs, which have a high temperature, are chiefly brackish, and the vapours which issued from numerous fissures, all indicate volcanic operations. No native inhabitants were found on the island when it was visited by the Lion man-of-war, with Lord Macartney and his suite, on their voyage to China; but three Frenchmen and two natives of England, who had emigrated to Boston at the end of the American war, were engaged in collecting seal skins for the Canton market. They had last come from the Isle of France, had resided five months in this sequestered spot, and had collected 8000 skins, nearly a third part of the cargo which they expected to complete in ten months more. Their vessel had sailed to Nootka sound, to procure sea otter skins, and was to call at Amsterdam island to take in the seal skins, all which were destined for the Chinese market. The *phoca ursina*, Lin. is the species of seal which is so abundant on the shores of this island as to become an important object of commerce. They are most numerous in summer, when they come on shore in droves of 800 or 1000, and a tenth part of the whole is killed by the five men, who could not skin and stretch out for drying a greater number. The sea abounds also with excellent fish, particularly a species of cod; a basket, with almost any kind of bait, let down into the sea, might be

Amulet || Ana. Anabaptists.

filled with cray fish in a few minutes; sharks and dog-fish of large size were numerous, and tench, bream, and perch were readily caught in the bason of the crater which forms the harbour, and being drawn out of the cold water, and immersed in a hot spring in the vicinity, they were completely boiled in about 15 minutes. The albatross, the black and blue petrel, and the sea-swallow, are the common birds which frequent Amsterdam-island. S. Lat. 38°, 42'. E. Long. 76°, 64'. St Paul's, a small island which lies in sight to the northward, is overspread with shrubs and trees of middling size, and is said to afford abundance of fresh water, but no good anchorage or a commodious landing-place could be discovered.

AMULET, a charm, or supposed preservative against disease or misfortune, which, under various forms, has prevailed among all nations during the darkness of ignorance and superstition; and, in more enlightened periods of society, is believed by some to possess a certain degree of efficacy. Amulets were worn about the neck, or attached to particular parts of the body; sometimes they were made of gems, metal, animal or vegetable matter; sometimes they consisted of words, characters, and sentences, arranged in particular order; and, even in the times of Christianity, the relics of saints, and ribbands, with texts of Scripture written on them, have been employed for the same purpose. Magic and astrology, which acknowledge a similar origin, have united their influence in providing certain kinds of amulets for the weak and superstitious.

AMYGDALUS, the almond and peach tree, a genus of plants belonging to the Icosandria class.

AMYRIS, shrubby sweetwood, a genus of plants belonging to the Octandria class.

ANA, a Latin termination, which has been adopted as a general title of certain works which profess to detail the unpremeditated thoughts and unrestrained sentiments of persons of learning and wit, as they are expressed in private conversation; and hence they are supposed to exhibit a just and lively picture of the characters introduced. How far these ends are attained by such collections, a slight notice of the history of some of them will shew. It has been said, that the title of these works is a word of doubtful origin; but it seems quite obvious, that the whole difficulty is at once solved by joining the word *dicta* to the name, which is converted into an adjective, as *dicta Walpoliana*, *dicta Scaligerana*; the sayings or remarks of Walpole, of Scaliger.

Works of this nature, it has been observed by those who have entered into their history, are not new. The deeds and sayings of Socrates were collected by Xenophon; and the maxims and precepts of Pythagoras, Epictetus, and other ancient philosophers, have been also recorded by their disciples and followers. It is said that Julius Cæsar formed a collection of anecdotes of Cicero, the celebrated orator; a freedman of Mæcenas, the great patron of literature in the Augustan age of Rome, recorded the sayings of his master; and the *Noctes Atticæ* of Aulus Gellius contain numerous anecdotes which the author gleaned from the distinguished characters with whom he associated. But it was not till the beginning of the 15th century that collections of this kind, with the mysterious title of *Anas*, or books in *ana*, made their appearance. One of the earliest and most celebrated of these works, is the *Poggiana*, which derives its name from Poggio Bracciolini, who was secretary to several popes. Poggio and his literary friends held frequent meetings, and conversed freely on every kind of subject; but as the investigation of truth, or intellectual improvement, was less the object of the assembly than a display of wit or licentious humour, whatever was the sacrifice, it is not difficult to appreciate such a work, especially when Poggio himself, the compiler, has denominated the place where the parties assembled, *Mendaciorum Officina*, or the shop of lies.

The *Scaligerana* was the first published work with this title, under which two collections have appeared, and profess to contain the remarks delivered in conversation by Joseph Scaliger, a professor of Leyden, and a profound classical scholar; but it is admitted that these collections are full of falsehoods, personal abuse, and silly, scurrilous, and obscene observations. But what shall be said of the freedom of conversation displayed in the *Segraisiana*, a collection which derives its name from Segrais, and which was compiled by a person concealed behind the tapestry in a house which he frequented? In such circumstances, with those at least who were in the secret, the flow of sentiment, and the current of conversation, could not be altogether uninterrupted. Voltaire has characterised the Segraisiana as the best entitled to all the works of this kind to be ranked among printed, and especially insipid falsehoods: but perhaps that celebrated wit had some reason for this strong expression of reprobation. The *Walpoliana*, which professes to exhibit the literary conversation of Horace Walpole, is one of the most recent of these productions, and one of the few which has appeared with this title in England. The plan of such a collection, it appears, was suggested to that accomplished scholar himself; but he wisely declined it, although, it is said, he supplied the editor of the collection with some of the materials of which it is composed. Part of it appeared after his death in a periodical publication; and the whole collection, supplied with new matter from various quarters, acquired considerable bulk, and was published in two volumes. Literary productions, whose origin and progress are such as have now been stated, can scarcely be free from mistatement and misrepresentation, if they are not entitled to a character of a more reprehensible nature.

ANABAPTISTS, a denomination which has been applied to religious sects of very different principles and practices. They first appeared in Germany, and excited serious commotions about the period of the reformation. The name signifies a person who is baptised again; and in this sense it is applicable to some sects in the earlier ages, who contended that those Christians of the Catholic church who joined themselves to their respective parties should be rebaptised. This denomination is rejected by the English and Dutch Baptists, who hold the baptism appointed by Christ to be nothing short of immersion upon a personal profession of faith, of which profession infants being incapable, and sprinkling being no adequate symbol of the thing intended, the baptism of proselytes to their communion, who in infancy had undergone that ceremony, cannot be, it is urged, considered a repetition of the baptismal ordinance. In the strictest sense, Anabaptists are those who not only re-baptise when they arrive at adult age persons who were baptised in infancy, but also as often as a person leaves one sect and joins another, or as often as he is excluded from the communion and again admitted into it; but the invalidity of infant baptism, in whatever way it is administered, is a tenet common to all sects of Anabaptists.

But some of those who assumed the name of Anabaptists professed principles of a different nature, and entertained peculiar notions of church establishment and its connection with human institutions. The plan of reformation proposed by Luther did not accord with their views. Their professed object was the foundation of a new church, which should be entirely of a spiritual and more perfect nature. The declaration of these doctrines soon increased the numbers and fanaticism of those who professed them; and the heads of the faction, Munzer, Stubner, and Stork, commenced their labours in Saxony in the year 1521. The arts of persuasion were at first resorted to, to disseminate their opinions, and to gain proselytes; but when the less powerful method of visions and revelations, which they pretended they received from heaven, failed, they had recourse to the more expeditious method of establishing their doctrines by force of arms. Munzer, and his associates, in 1525, saw themselves at the head of a numerous army, collected from all parts of Germany, and declared war against all human institutions, under the pretext that Christ was to take the reins of government into his own hands, and to reign over the nations. But this lawless rabble was soon routed and dispersed, and Munzer, their leader, was ignominiously put to death.

Many of his followers survived, and continued to propagate their opinions in different places on the continent. A party settled at Munster in Westphalia, in 1533, under the direction of John Matthias, a baker of Haerlem, and John Bockholdt, a journeyman taylor of Leyden. Aided by a powerful party from the country, they seized on the arsenal and senate-house in the night-time, and with drawn swords, and dreadful howlings, ran through the streets, crying out, "repent and be baptised, and depart ye ungodly." In the midst of this scene of confusion and disorder, the magistrates and the respectable part of the inhabitants fled, and left the fanatics in undisturbed possession of the city. Matthias framed a new constitution, ordered every man to bring forth his money and valuable effects, and deposited the wealth thus accumulated in a public treasury, for the common benefit of all. The members of the new commonwealth were commanded to eat at public tables, and the very dishes which were to be daily served up were specified; and at the same time he did not forget to provide prudent means for the defence of the city, which was dignified with the name of Mount Zion. The bishop of Munster advanced with an army to besiege the town; the fanatical leader sallied out, attacked his camp, and, after a severe conflict, returned to the city loaded with rich spoils. Elated by success, he appeared among his followers next day, and declared, that, like Gideon, he would, with a handful of men, smite the ungodly. Thirty persons were selected to accompany him in the mad enterprise of attacking the enemy, but not one escaped. After the death of Matthias, Bockholdt assumed the government, and declared himself the king of Zion; and under the pretext of Christian liberty, of being altogether unrestrained by the regulations of human institutions, he and his followers indulged themselves in all kinds of indecencies, and were guilty of every species of licentiousness. Among other practices, a plurality of wives was inculcated, and the leader himself, to exhibit a proper example, had fourteen wives. To suppress these disorders, the German princes furnished supplies of men and money to the bishop of Munster, who besieged the city, and reduced it to the utmost distress for want of provisions. The walls were scaled in the night by a party of the besiegers, who, unperceived by the enemy, opened the gates to their companions, and the fanatics being thus surprised, were, after an obstinate but ineffectual resistance, either put to the sword, or taken prisoners, after fifteen months possession of the city. Bockholdt himself was taken prisoner, and after being carried about from city to city, and exhibited as a spectacle, was cruelly tortured, and put to death at Munster.

Those who have adopted the doctrines of this sect in the present day not only renounce their licentious tenets and practices, but even reject the name of Anabaptist. In England they are denominated Baptists; in Holland Mennonites, from Menno their great reformer, and sometimes Waterlandians, from Waterland, a district of North Holland.

ANABASIS, a genus of plants belonging to the class Pentandria.

ANABOA, a small island near the coast of Loango, in Africa, which contains several fertile valleys, and produces large quantities of cotton, and abundance of all kinds of tropical fruits. N. Lat. 1°. E. Long. 9°.

ANACARDIUM, the cashew nut tree, a genus of plants belonging to the class Enneandria, one species of which, *anacardium occidentale*, is a native of the West Indies, and produces an agreeable acid fruit, which is sometimes employed as an ingredient in punch, and the cashew nut, which is frequently brought to this country, grows attached to the end of the fruit.

ANACHARSIS, a Scythian philosopher, who flourished 600 years before Christ, was the son of a person of rank in his nation, and a Grecian lady. By her he was instructed in the Greek language, and acquired a taste for Grecian literature. He was appointed by his fellow-citizens on an embassy to Athens; and having resided several years in that celebrated city, he travelled into different countries in quest of knowledge, and returned to his own for the purpose of instructing his countrymen in the laws and religion of the Greeks; but they were not prepared to receive the wisdom and learning of that polished people. While he was performing sacrifice to the goddess Cybele, he was slain by an arrow, which is said to have been discharged by the hand of his own brother, who was then king of Scythia, and was little disposed to encourage the innovations of Anacharsis. The history of Anacharsis has furnished the subject of a popular work, the Travels of Anacharsis, by Barthelemy, an eminent French writer.

ANACHORET, or ANCHORET, a hermit or solitary monk, who retires from human society, to avoid the temptations of the world, and to devote himself to meditation and prayer. Anachorets, among the Greeks, were chiefly monks who retired to caves or cells, with the permission of the abbot, and an allowance from the monastery; or such as were tired of the service of the establishment, purchased a spot of ground to which they might retreat and spend their days, returning to their monastery only on solemn occasions.

ANACHRONISM, from two Greek words, which signifies *above* and *time*, is an error in chronology, by which an event in history is placed at an earlier period than when it really happened; as when Virgil places Dido in Africa at the time of Æneas, which was 300 years before the actual period; but, in a more general signification, it is applied to any error in time, whether the event shall have happened at an earlier or later period than what is specified.

ANACLASTIC GLASSES, a kind of low flat bottles, resembling inverted funnels, and having the bottom, which is slightly convex, extremely thin. These glasses, from the flexibility of the bottom, emit a considerable noise, merely by the action of the breath. By breathing into a bottle of this description, the convex flexible bottom becomes concave, and, by sucking out the air it returns to the convex state, and from these motions of the flexible bottom the sound proceeds. By breathing strongly into these vessels, there is considerable risk of fracture; and even a gentle inspiration when the bottom is concave, or drawing out the air when it is convex, produces the same effect. These glasses are manufactured in Germany, where the property was first observed.

ANACREON, a celebrated lyric poet of Greece, who was born at Teos, a city of Ionia, and hence is frequently called the Teian bard, flourished about 530 years before Christ. His poetical talents procured for him an invitation to the court of Polycrates, the tyrant of Samos, and he lived to the age of 85, when, it is said, he was choaked with a grape stone, which stuck in his throat while he was regaling himself with new wine. A few fragments only of the works of Anacreon are extant, and both of the poet and his writings very opposite characters have been drawn; for while he is charged by some with licentiousness and sensuality, he is held up as a model of moral purity and virtue by others. His verses are described by one critic as sweeter than Indian sugar. His beauty and chief excellence consist in imitating nature, and in presenting to the mind only noble and natural images. The odes of Anacreon, says another, are flowers, beauties, and perpetual graces. Flowing always soft and easy, the joy and indolence of his mind are diffused through his verse, and his harp is tuned to the smooth and pleasant temper of his soul. The English translation by Mr Moore is perhaps not surpassed by the original.

ANACREONTIC verse, or poetry, is that which imitates the poetry of Anacreon, and is descriptive of amatory or bacchanalian subjects. This far-famed poet has found imitators in the Latin, English, and German languages. The most successful among the last are Lessing, Kleist, Goetz, and, above all, Gleim, who has been distinguished by the name of the German Anacreon. When the word is restricted to the structure of the verse, it refers to that which consists of three feet and a-half, and is usually composed of spondees and iambuses, and sometimes anapæsts, as the verse of Horace:

Lydia, dic per omnes.

ANADYR, a river of Siberia, which derives its origin from a lake, and, running to the south-east, falls into the sea of Anadyr, which is part of the Pacific ocean. This river forms a singular boundary between two very different countries. A region of absolute sterility lies on the north, while the country on the south side is covered with lofty forests or rich pastures.

ANAGALLIS, or Pimpernel, a genus of plants belonging to the class Pentandria, two beautiful species of which are natives of this country.

ANAGNOSTA, or *Anagnostes*, a kind of literary domestic in the families of persons of distinction among the Romans, whose business was to read to them at their leisure hours, and particularly during meals. The emperor Charlemagne, who greatly encouraged literature and learned men, established a similar practice, and the same custom was observed by the ancient monks and clergy.

ANAGRAM, from two Greek words, signifies the transposition of the letters of a word or sentence, so that a word or sentence of a different signification is formed, as when *angelus* is formed from the word *Galenus*; *Alcuinus*, which is the anagram of *Calvinus*, and assumed by Calvin in the title of his Institutions. An anagram is sometimes formed by dividing one word into several, as the three words *sus, tinea, mus*, which are names of animals formed from the verb *sustineamus*. As an example of an anagram formed of a sentence, the question put by Pilate to Jesus Christ, *quid est veritas?* has been transposed into an answer *est vir qui adest*; but the ingenuity of the learned is now rarely occupied in this trifling literary amusement, for which, even in the 17th century, a composer of anagrams was retained, with a pension, at the French court.

ANAGYRIS, stinking bean trefoil, a genus of plants belonging to the class Decandria.

ANALEMMA, a projection of the sphere on the plane of the meridian, orthographically made by straight lines and ellipses, the eye being supposed at an infinite distance in the east or west points of the horizon. The same word also denotes an instrument of brass or wood, on which this kind of projection is drawn, and it is employed to solve astronomical problems.

ANALOGY denotes a certain relation and agreement between two or more things, which, in other respects, are altogether different. A great deal of the reasoning of mankind depends on analogy; and when it appears that the things compared have a great resemblance, it is fair to conclude that they are subject to the same laws. Thus, in observing the appearances in the motions of the planets which belong to the solar system, and in discovering a resemblance between their motions and those of the earth, a strong degree of probability is obtained that these planets are the habitations of various orders of living beings.

But as reasoning from analogy affords only probable evidence, great caution is necessary to avoid error in employing forced resemblances and inaccurate comparisons. Comparative anatomy furnishes an excellent example of just analogy in examining the teeth of the huge animals whose bones were discovered in the western regions of America, and in concluding from the resemblance which is observed between them and those of a race of animals existing at the present day, and whose habits are well known, that the fossil teeth belonged to graminivorous animals; and an example of false analogy is derived from a comparison of the *stapelia*, a genus of plants which are natives of the arid deserts to the westward of the cape of Good Hope, and are remarkable for their succulency, with the camel, which is furnished with a peculiar bag or stomach for retaining a supply of water to support the animal in its fatiguing journies through the burning sands, and from this mistaken resemblance the stapelia has been, with little propriety, denominated the *camel of the desart*. But the structure, functions, and habits of the plant and animal present no precise similarity, and any conclusions drawn from the one and applied by analogy to the other must prove erroneous. Reasoning by analogy is extensively and successfully employed in Bishop Butler's celebrated work on the "Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature."

ANALYSIS, in its general acceptation, signifies the resolution of something compounded into its original and constituent parts. *Mathematical* analysis is the method of investigating a proposition to some known operation, or acknowledged principle. *Logical* analysis consists chiefly in combining our perceptions, arranging them into classes, and communicating our thoughts under appropriate forms of expression, and representing their several divisions, classes, and relations. *Chemical* analysis is the decomposition of a compound body, or the separation of its principles or constituent parts. The same word is employed to denote a syllabus, or table of the principal heads and subdivisions of a discourse arranged in the order and relative connexion in which the subject is treated.

ANAMABOA, a town in the kingdom of Fantin, on the Gold Coast of Africa. The town is one of the most opulent and populous upon the coast, and the neighbouring territory is distinguished by a rich and productive soil, which affords abundance of corn and fruits. Anamaboa was formerly considerable for the slave trade, for the protection of which the English erected a fort in the immediate vicinity of the town, and is still understood to be a place of some trade.

ANAMOOKA, or ROTTERDAM, an island forming one of the groupe called Friendly Islands, in the Pacific ocean, is about 18 leagues distant from Amsterdam island, to which it has a strong resemblance in appearance, soil, and productions. The chief harbour is on the south-west side; the greater part of the coast is precipitous towards the sea, and the reefs and sand-banks which surround the island render navigation dangerous.

ANAMORPHOSIS, a deformed or distorted representation of an object, which, being seen from a certain point, or reflected from a plane or curved mirror, assumes its natural or proper form, and appears in just proportion. See OPTICS.

ANANAS, a species of Bromelia, or the trivial name of the pine apple.

ANAPÆST, a foot in Latin poetry, which is composed of two short syllables and one long, as *scŏpŭlōs*. Anapæstic verses consist entirely of such feet.

ANARCHICAS, or Wolf-fish, a genus of apodal fishes. See ICHTHYOLOGY.

ANAS, a genus of birds belonging to the order of Anseres. See ORNITHOLOGY.

ANASTATICA, or Rose of Jericho, a genus of plants belonging to the Tetradynamia class.

ANATHEMA, from the Greek word which signifies to deposite or lay down, was an offering presented to some deity, according to the views of ancient mythology, and this offering was either laid on the floor of the temple dedicated to the god, or suspended from the wall. By offerings of this kind, the persons who had escaped from shipwreck or other imminent danger, or who had enjoyed a large share of prosperity, expressed their gratitude to the patron deity who presided over their good fortune. The usual offerings on such occasions were garlands, crowns, garments, or vessels of gold or silver. It was not unusual also for those who retired from any occupation, to dedicate the implements of their trade or profession to the presiding divinity.

ANATHEMA is also employed to denote the separation of a person from the society and privileges of the church to which he belongs, and is different from simple excommunication, because it is accompanied with curses and execrations. The anathema was practised in the primitive Christian church against great offenders. It was expressed according to the following form:—"Let no church of God be open to Andronicus, but let every sanctuary be shut against him. Private men and magistrates are admonished to receive him neither under their roof nor at their table; and priests more especially, that they neither converse with him living, nor attend his funeral when dead." Anathemas are pronounced against such as should attempt to corrupt the purity of doctrines; "If any one should be thus guilty, let him be *anathema*." Anathemas are either judiciary, when they are denounced by a council, the pope himself, or a bishop; or abjuratory, when a convert to be received into the bosom of the church renounces and anathematises the heresy which he abjures.

ANATOMY.

Introduction

THAT part of natural science which teaches the investigation of the structure and functions of animal bodies by dissection, is called *Anatomy*, from the Greek word which signifies to *cut up* or *dissect*. In treating this subject, it has been usual either to consider merely the *structure* of animal bodies, or to combine with that examination only those functions which are called *organic*, and which are explained chiefly by the structure of the organs by which they are performed. But, in the present treatise, we propose to take a general and connected view of the *whole animal economy*, in all the various classes of animated nature, from man to the lowest tribes of those beings which possess life and voluntary motion.

INTRODUCTION.

All the objects of nature, when compared together, are capable of being arranged under one or other of two great divisions. Some of them are composed of parts that are easily separated without destroying the nature and properties of the whole; they increase by the approximation or aggregation of their component particles, and possess no inherent power of resisting those changes that may be produced on them by external agents. Such are called *inorganic* bodies, or crude matter, and compose the numerous *mineral* substances which are dug from the bowels of the earth, or lie motionless upon its surface. Others again have their component parts arranged in *systems* or *organs*, which are generally different in different parts of the same body; they increase by *growth*, and nourishment, and they possess within themselves, to a certain degree, the power of resisting the effects of other bodies. These are called *organized* beings, and are said to be composed of *living matter*. Such are *plants* and *animals*.

General Anatomy may be said to include the consideration of the structure of both these divisions of organized beings; but as the anatomical examination of plants is generally treated of under *Botany*, we shall here confine our attention entirely to the *animal* kingdom.

Division.—Anatomy has been divided into *human* and *comparative*, the former being confined to *man*, the latter extending to the *inferior animals* compared with man or with each other. The present treatise is intended to be strictly comparative in the former sense, for though we shall take man as our model, and be more minute in our account of his structure and economy than in that of the brute creation, we shall be careful to notice all the more remarkable peculiarities which distinguish other animals from the human species.

Advantages of anatomy.—On the utility of anatomy and physiology, much might be advanced; and indeed there are few subjects more interesting, whether we consider them in themselves, or as forming a necessary and important introduction to other sciences, particularly natural history and medicine. In contemplating the works of nature, with the view either of gratifying a laudable curiosity, or of making ourselves acquainted with those objects that continually surround us, and either minister to our wants and comforts, or oppose and obstruct us in our pursuit of these comforts; or with the more sublime and elevated view of raising our minds and affections "from nature up to nature's God;" all are peculiarly interested in the study of the *animal* economy. The structure and functions of man, and of those animated beings that resemble him, are objects which demand the particular attention of those who are to devote themselves to the medical profession, as they constitute the very foundation of medical science. To the zoologist, who wishes not merely to study the habits and manners of animals, but to understand the nature and principles of modern classification, comparative anatomy is essential, as the characters of the classes, orders, and genera of animals, are drawn as much from their intimate structure as their external forms. Several artists, too, as the painter and the statuary, require a pretty correct knowledge of the forms and proportions of the animal body before they can faithfully represent them in a picture or a statue. The prominences of the bones, the rounding of muscles, in their ordinary state of quiescence, as well as when rendered more prominent by action, must all be accurately studied; and that artist who knows them best will most successfully copy nature, and of course please most in his profession.

Introduction

Before entering on a particular examination of the structure and economy of animals, it will be of great importance to take a general comparative view of the organic functions in the order in which we propose to consider them.

The organic functions of animals are, *Motion*, *Sensation*, *Digestion*, *Absorption*, *Circulation*, *Respiration*, *Secretion*, *Excretion*, *Integumation*, and *Reproduction*.

Voluntary motion.—All animals possess the faculty of voluntary motion, though this function, and the organs subservient to it, are extremely different in degree and complication in the several classes of animated nature. The more perfect animals have solid organs, called *bones* and *cartilages*, or gristles, connected together by *ligaments*, so as to form joints or *articulations*. These bones are set in motion by fleshy fibrous organs, called *muscles*, generally connected to the bones by *tendons* or sinews. Many classes and tribes of animals have however no bony system, though all must possess something analagous to muscles. That part of anatomy which describes the bones of an animal is called *osteology*; that which describes the ligaments is called *syndesmology*, and that which treats of the muscular system is denominated *myology*.

Sensation.—As a connecting link between voluntary motion and sensation, all animals must possess certain sentient organs, though, in all, these are not distinctly perceived. In what are called the more perfect animals, the sentient organs are very complicated, consisting of a pulpy mass within the head, called *brain,* and numerous filaments or cords connecting this with various parts of the body, and called *nerves.* These nerves in many cases form knots called *ganglions,* and sometimes they are connected with each other into a sort of net-work called *plexus.* A great proportion of the animal kingdom have nerves, without a brain, and in many even the nerves cannot be distinctly traced. That part of anatomy which treats of the brain and nerves, or *nervous system,* is denominated *Neurology.*

Digestion.—Animals are farther distinguished from plants by their mode of growth. They do not, like the latter, merely imbibe nourishment from the medium in which they live, but receive the means of support into a particular cavity, where it undergoes certain changes, which fit it for becoming part of the animal body. In this function, which is called *digestion,* animals also differ considerably from each other. In some the apparatus is still more complicated than in the two functions already noticed. In some the food is received into a mouth, chewed or *masticated* by teeth and gums, swallowed by a *gullet,* whence it is carried into a stomach, and, after remaining for a certain time, passes into a continuation of the same tube, called *intestines,* to undergo those changes which fit it for nutrition. Many animals have a mouth, but no teeth; some, as having no head, are destitute of both, though they possess both stomach and intestines; while others have only one short cavity, serving at once the purpose of mouth and intestinal canal.

Absorption.—After the food has undergone the necessary digestive process, the nutritious particles of it are taken up by particular tubes, thence called *absorbent,* and either carried directly to their place of destination, as in the more simple animals, or conveyed through a more or less complicated apparatus of tubes and bodies called *glands,* to a common reservoir, from which they are afterwards distributed to those organs of which they are to form a part. This function is called *absorption,* and the organs subservient to it the *absorbent system.*

Circulation.—All animals have the body composed partly of solids and partly of fluids. In a great proportion of them the fluids are in considerable quantity, and constitute what is called their *blood.* This blood is contained in innumerable canals or *vessels,* communicating with each other, and in most cases composing two sets or systems. In all the more perfect animals, the blood continually moves from the larger parts or *trunks* of one set of vessels, called *arteries,* to the extremities of their *branches,* whence it enters the branches of the second set of vessels, called *veins,* and proceeds through the trunks of these latter to a common reservoir or centre. This centre is a hollow fleshy cavity, more or less complex, called the *heart,* the use of which is to propel the blood into the arteries and receive it back from the veins; this function is called *circulation,* and the whole apparatus of heart, arteries, and veins is called the circulating or sanguiferous system. That part of anatomy which treats of this system is called *Angeiology.*

Respiration.—In all the animals with which we are acquainted, the continual or occasional presence of atmospheric air is necessary for the perfect performance of their several functions, though many of them do not carry on what can properly be called *respiration.* In the higher classes, however, there is a peculiar set of respiratory organs adapted to the medium in which they usually reside. Those which live entirely or chiefly in the air, respire by means of membranaceous spongy bags called *lungs,* which are alternately distended and contracted during *inspiration* and *expiration.* Again, those which live entirely in the water respire through vascular plates, called *gills.* Many of the less perfect animals also possess respiratory organs similar to gills, denominated *branchiæ.*

Secretion.—In all those animals which possess a true circulating system, and in those which have only vessels for containing the general fluids, certain parts are continually separated from the general mass of blood, to answer some important purpose in the animal economy. This function is called *secretion,* and the organs subservient to it *secretory* organs. On these we cannot at present dwell, but shall treat of them in their proper place.

Excretion, &c.—There is a function similar to secretion, by which the useless, noxious, or *excrementitious* parts of the food or fluids are thrown out of the body. This is called *excretion,* and its organs *excretory* organs. All animals have the faculty of reproducing or propagating their like. In most cases this is effected by peculiar organs; but in some, as in the lowest tribes of animated nature, the young are produced by shoots or offsets from the parent animal.

Those organs, which are contained within the principal cavities of the animal body, are technically called *viscera*; and that part of anatomy which treats of them is called *splanchnology.*

All the organs now enumerated are connected together, lined, or covered with extensive expansions, denominated *membranes*; and the whole body is covered and defended by *integuments.*

Diversity of structure.—On comparing the different tribes of animated nature with respect to their structure, we find that they may be conveniently distributed under two great groupes. Some of them have an internal skeleton, or assemblage of bones united together by moveable joints; and, in particular, they have a series of these articulated bones, extending from the head to the opposite extremity, called by anatomists the *vertebral column.* These are hence called vertebral animals, and include man, quadrupeds, cetaceous animals, birds, reptiles, serpents, and fishes. The other great subdivision of animals has no internal skeleton, and of course no proper vertebræ. These are, therefore, invertebral animals, and comprehend those classes which are called crustaceous animals, insects, mollusca, worms, and zoophytes.

The vertebral animals have all more or less of a brain within the cavity of the head. Some of them have a heart, with two independent fleshy cavities, called *ventricles,* for propelling the blood into the vessels that convey it through the body; and the blood contained in these vessels is said to be warm, because it considerably exceeds the medium temperature of the atmosphere. These are called warm-blooded animals, and they breathe by means of *lungs.* Some of them are *viviparous*, or bring forth living young, which they suckle by means of teats, as man, quadrupeds, and cetaceous animals; while others are *oviparous*, or produce eggs, which are afterwards hatched, and do not suckle their young, as birds. In the other subdivision of vertebral animals, we find a heart, either with a single fleshy cavity, or with two, which freely communicate with each other; and their blood is said to be cold, as its temperature is seldom much greater than that of the air or water which they inhabit. These are the *cold-blooded* animals. They are all essentially oviparous. Some of them have lungs and jointed members, as reptiles; others have lungs, but no jointed members, as serpents; and the rest breathe by means of *gills*, as fishes.

The invertebral animals have no brain. Some of them have an external articulated case, which cannot properly be called a skeleton, and jointed members; while others are destitute both of articulated case and jointed members. The first subdivision of invertebral animals comprehends the crustaceous animals and insects; the former having a circulating system, and generally a calcareous covering, and breathing by means of gills, called *branchiæ:* the latter without circulating system, having a horny external covering, and breathing by means of porous organs, called *tracheæ*. The second subdivision of invertebral animals comprehends those which have simple nerves, called *mollusca*; those which have knotted nerves, generally denominated worms; and those which have no perceptible nervous system, called *zoophytes*.

Living power.—The remarks now offered embrace a general view of the organic functions which distinguish organized beings from inorganic matter, and refer to the property of resisting the effects of external agents possessed by the former. We shall now consider the nature and effects of that cause which enables organized beings to resist those changes to which brute matter is continually exposed. We find that this power resides in organized beings only for a time; and that a period at length arrives, when they are as much exposed to the action of chemical powers as the minerals which form a part of the substance of the earth. When that period arrives, their organical functions have ceased to act, and the organized body has lost something by which these functions were supported. This something is distinguished by the name of *life*.

Life, then, is *that power by which organized beings are enabled to resist external agents, and to carry on their organical functions.* Of its essential nature we know nothing, as we see it only by its effects. The cause of life, whatever it may be, is called the *vital principle*, or the principle of vitality; and this principle exists in all organized beings, which are therefore called living beings. It does not, however, exist in an equal degree in all living beings, or reside in the same proportion in all parts of the body. Those animals which possess the fewest functions, as zoophytes, seem also to possess a lower degree of vitality; but it is more equally diffused throughout their substance. If a polype be cut in pieces, each piece lives and grows, and in time becomes a complete polype. The more perfect animals, who exercise all the organical functions which we have enumerated, also possess the highest degree of vitality, but possess it more completely in some particular organs, as the heart, the brain, or the stomach. The heart of a frog palpitates for some hours after it is removed from the body; and the head of a turtle or a snake has been known to bite for hours, or even days, after separation. In the higher classes, only the *cuticle*, or scarf-skin, the *hair*, and *nails*, or analogous parts, are entirely destitute of life.

All animals are not equally tenacious of life; and, in general, the more perfect the animal, that is, the greater the number and complication of its functions, the more easily is it deprived of life. A sudden violent blow on the temple or the stomach is often sufficient to kill a man; the insertion of a pointed instrument into the spinal marrow, instantly converts a living ox into a dead carcass: but an eel may be flead alive, and cut in several pieces, and still shew evident marks of vitality; a salamander may be deprived of its heart, and still swim about as usual; and a tortoise may have its brain scooped out from the cavity of the skull, and still walk about with apparent indifference.

The duration of life is extremely various, but generally keeps pace either with the complication of the functions, or the tenacity of the vital principle. There are insects which, in their perfect state, live but for a day; others of the same class enjoy existence for a summer, or a year or two;—while, in the higher classes, the existence of a few, as the raven and the elephant, is prolonged for nearly a century; and man, the lord of the creation, though generally restricted to threescore and ten, is sometimes found to linger out for more than a century and a half.

Chap. I. Of the Bones and Organs of Motion.

The bony system of animals cannot properly be said to constitute any part of their organs of motion, but rather furnishes the levers and *fulcra*, or props on which the moving organs act, while it gives strength and solidity to the whole animal machine. It is to the bones that the body owes its diversity of figure, and these solid parts form the cavities in which the more important organs are lodged, and by which they are defended.

Sect. I. *Of the Bones.*

Nature of bones.—In their substance the bones are the most solid parts of the body, being formed in a great measure of that peculiar earthy substance called *phosphate of lime*, cemented together by animal gelatinous matter. In a full grown body the bones are more or less of a white colour, especially on their outer surface, but in young animals they are bluish, and sometimes of a reddish colour. When cut or broken in a living animal, the inside exhibits the appearance of numerous red points. In general they are harder on the external surface than within, and this hardness increases with age.

Form.—The form of the bones differs considerably in various parts of the body. Sometimes they are long and nearly cylindrical, as those of the arm, thigh, and leg; sometimes they are flat, and of an oblong or rounded form, as the blade-bones; at others they are arched, so as to be convex on the one side and concave on the other, as the bones of the skull; and frequently they are very irregular in their form and structure. They are generally described as being composed of a body and *processes*, or protuberances, and these processes receive different names according to their form and relative position. The round protuberances at the extremities of the long bones are called *heads*, which are sometimes united to the body of the bone by a contracted part called *neck*, and, when formed so as to move like a hinge on other bones, *condyles*; when round and rough they are called *tuberosities;* when extending to meet another bone, so as to form an arch, *zygomatic;* and sometimes they are denominated *mastoid*, *styloid*, *pterygoid*, *coracoid*, &c. according as they are supposed to resemble a nipple, a pencil, or *stylus*, a wing, a bird's beak, &c. These processes, and in general the extremities or edges of a bone, and sometimes its superficial cavities, are covered with cartilage, which is often smoother, more elastic, and of a bluer colour than the bony substance.

Cavities.—The bones have also various cavities, hollows, or depressions. Some of them, as the long bones, have an internal tubular cavity, extending for a considerable length; others have large hollows, called *sinuses*, formed within their substance; some have external hollows, more or less deep, for receiving the heads or condyles of other bones; and in most bones there are furrows, canals, or holes, for the passage of blood-vessels or nerves. In general, the extremities and protuberant parts of bones are more loose and spongy, in their internal texture, than the body or middle of the bone; and sometimes the texture is so loose that numerous cells are formed communicating with each other.

Covering.—Bones are covered on their outside with a fibrous membrane, called *periosteum*, and their internal cavities and cells are lined with a similar but more delicate membrane, of a net-like texture. Within the interstices of this latter membrane there is lodged a thick oily matter called marrow.

Formation of bone.—In a *fœtus*, or young animal, before birth, the bones are in a soft or gristly state, and gradually acquire their proper consistence as the animal advances towards maturity, the gristly substance being removed and replaced by bony matter. This process is termed *ossification*, and takes place in a very gradual but uniform manner. A few white specks appear first in the middle of what is to form the body of the bone; these gradually increase till they form fibres, which either run in a radiating direction from a common centre, as in the flat bones, or extend in successive bony rings from the middle to the extremities, as in the cylindrical bones. In the *fœtus*, too, each bone is made up of several pieces, which are afterwards united; and commonly the process of ossification is going on at the same time in each of the component pieces.

Articulation.—The bones are connected or articulated together in several different modes, according as they are immoveable or moveable on each other. Sometimes the edge of one bone is intimately and closely united to that of another, so that their juncture is scarcely visible; sometimes the edges are indented into each other as if they were stitched together, forming what is called a *suture;* in a few instances, the edge of one bone lies over that of another, like a scale; and, in others, one bone is firmly fixed in the body of another, like a nail in a piece of wood. All these connexions are immoveable. Of the moveable articulations there are three principal kinds; 1st, where the extremity of one bone moves on that of another, like a hinge, as in the elbow and knee; 2d, where the head of one bone moves in almost all directions within a cavity or depression of another, as in the shoulder and hip-joints; and, 3d, where one bone moves upon another by a sort of rotatory motion, as the hand upon the elbow, or the head upon the neck. Anatomists have enumerated many more varieties of articulation, and have given to each appropriate names.

Ligaments.—The articulations of the bones are protected by strong fibrous membranes, extending from one bone to another. These are the *ligaments*, and have received different names according to their situation and direction. Thus, there are *central* ligaments, extending from the head of a bone to the cavity in which it moves; *capsular* ligaments, forming a bag, more or less loose, round the head of a bone and the brim of its receiving cavity; *lateral*, *crucial* ligaments, &c. The extremities of these ligaments are sometimes attached immediately to the bone or cartilage; but in general they are united to the bones through the medium of the *periosteum*.

Mucous follicles.—In the moveable articulations there are several circumstances to be considered, which assist the motions of one bone upon the other. In all the principal joints there are little bags, or hollow membranes, containing a glairy mucilaginous fluid, so situated that the pressure produced by the motion of the joint squeezes out a portion of the fluid, so as to lubricate the contiguous surfaces of the articulated bones, as oil assists the motions of machinery by diminishing the friction of one part upon another. The fluid thus prepared within the cavities of joints is called *synovia*, and the membranes which contain it are termed synovial bags, or *mucous follicles*. The fluid itself, in colour and consistence, resembles the raw white of egg.

Moveable cartilages.—Besides this synovial apparatus, there are, in some of the joints, moveable cartilages between the articulated surfaces, which being compressible and elastic, tend to diminish both the pressure on the lower bone and the friction of the bones upon each other. In other joints, as those of the back, there is sometimes an elastic substance, resembling cartilage, but immoveable, interposed between the bones; and sometimes, as in fishes, each of the contiguous bones forms the half of a double close cavity, filled with a mucilaginous fluid, resembling the synovial apparatus.

General remarks.—The greater blueness or redness of the bones in young animals depends on their greater vascularity, or the greater proportional quantity of blood that circulates through them. As the animal advances in age, and especially after he has acquired his full growth, many of the vessels in the bones become obstructed or obliterated; hence a less proportional quantity of blood is transmitted through them, and they become of a whiter colour, and harder consistence.

The cavities, and internal spongy texture of bones, make them both lighter and more capable of resisting external force, while they serve to contain the marrow, which helps to keep the bones sufficiently moist and flexible. The larger extremities and processes of bones serve for the attachment of ligaments and muscles, while they facilitate the motions of the animal.

The periosteum, besides other uses to which we cannot at present properly refer, assists in checking the overgrowth of the bones, strengthens the connection of the bones with their ligaments and cartilages, and helps to protect them from external injuries.

The division of each bone into several parts, in the young animal, has several important uses. It enables the animal to occupy a smaller space before birth, by increasing its flexibility; it materially assists the easy exclusion of the fœtus at birth, and it accelerates the formation of bone by increasing the number of ossifying points.

Diversity in different animals.—The differences in the general structure of the bony system, in the various classes of animals, are not very considerable. The bones of quadrupeds resemble those of man, except that in the larger species they are proportionally stronger, their texture coarser, and their prominences more distinctly marked. The whale tribe of animals have the fibrous texture of their bones looser than that of man and most quadrupeds, and the internal cavities more conspicuous, and filled with a thinner and more oily fluid. In birds the bones have also very large internal cavities, but they are destitute of marrow, and are filled only with air, a structure which contributes materially to increase the buoyancy of those animals in the atmosphere. In one order of fishes the skeleton is entirely cartilaginous, and in the rest the proportion of gelatinous, compared with that of earthy matter, is very great. In reptiles and serpents the texture of the bones is very uniform, and, in some cases, their solidity is very considerable. In these animals, as well as in fishes, the bones are much more simple in their form, and have fewer prominences than those of the superior animals.

The hard parts of the invertebral animals, though sometimes called their external skeleton, have little analogy with the bones of vertebral animals, except in similarity of substance. They are more properly integuments than skeletons, and, with the horns, hoofs, and nails, will fall to be considered under the head of INTEGUMATION. We now proceed to describe the several parts of the skeleton, which is usually divided into the head, trunk, and extremities.

Bones of the Head.—The head is composed of numerous pieces, connected together, with only one exception, by immoveable articulations. The component bones are conveniently arranged in two groupes, those of the skull and those of the face.

Bones of the skull.—In man, the skull, or brain-case, called by anatomists the *cranium*, is composed of eight bones; one forming the forehead, and composing the upper part of the orbits or sockets of the eyes, termed the *frontal bone;* a second forming the back part of the head, called *occipital bone;* two lying between these at the top of the head, the *parietal bones;* one placed on each side below the parietal, forming the temples, and called *temporal bones;* a seventh, connected with the frontal bone, above the root of the nose, called *ethmoidal;* and an eighth, wedged in the lower part or *base* of the skull, called *sphenoidal bone.*

The *frontal bone* extends in front between the two prominent points that may be felt on the temporal sides of the orbits, and, forming two arches below the eyebrows, runs down a little in the middle to meet the nose. From the orbitar processes it runs backward about an inch on each side forming part of the temples, and then takes a semicircular sweep nearly over the top of the head.

The whole top of the head, and part of its sides, backward from the frontal bone, are formed by the *parietal bones,* which are each of an irregular four-sided figure, united to each other in the middle of the top of the head, by a straight suture called the sagittal suture, and to the convex edge of the frontal bone by two concave edges, forming the coronal suture.

The *occipital bone* forms that remarkable protuberance or ridge at the back of the head, is of an oblong, irregular, four-sided figure, with very obscure angles, and is united to the parietal bones, and to those that are immediately to be described, by a suture, which, from its fancied resemblance to a Greek letter, has been called lambdoidal. This bone has several remarkable ridges and depressions on its lower surface, and a very large oval hole near its anterior extremity, and towards the fore part of this hole there are two remarkable protuberances or condyles.

The *temporal* bones form the rest of the sides of the head, occupying the region of the ears, and may be readily distinguished in the living body by a remarkable protuberance behind the ear at their back part, and by an arch extending from the fore part of the ear towards the cheek. Each is composed of two parts, one called the *squamous portion,* thin and broad, overlapping the parietal bone, and an irregular, very hard, and thick part, called the *petrous portion,* extending inwards, and containing the organ of hearing, with a remarkable external orifice, by which it communicates with the air. The projection behind the ear is called the *mastoid,* and the arched portion before the ear the *zygomatic process.* Besides these there is a remarkable long and pointed process, not perceptible externally, called the *styloid,* which runs forward and inward, and serves, like the two former, for the attachment of muscles.

The *ethmoidal bone* is the smallest of those that belong to the skull. No part of it is perceptible externally, but it occupies the upper part of the nose and of the space between the eyes. It is composed chiefly of a spongy body, full of cells, that are lined with a membrane, having an upper plate perforated with numerous holes, from the middle of which rises a thick, flat process, upwards within the skull, while from its lower surface there descends a similar plate of larger dimensions, forming part of the partition that separates the nostrils from each other. The sides of this bone next the orbits are flat and smooth.

The *sphenoidal bone* is exceedingly irregular, and its figure is not easily understood without actual observation. The body of it is wedged in the base of the skull, and from it extends a broad process on each side to meet the temporal parts of the frontal bone, while two other long processess, with deep furrows on their back part, pass downwards at the back of the mouth, and between these latter is a sharp ridge. This bone is pierced with numerous holes, and within the substance of its body are two of those large cavities called sinuses.

Interior of the skull.—In the above descriptions we have purposely avoided the inner surface of the bones, which we shall now notice in giving a general view of the interior of the skull. The upper part and sides of this cavity are nearly smooth, except a few superficial depressions and furrows, marking the protuberances of the brain and the course of blood-vessels; but its lower surface, or *base*, is rendered very unequal by numerous hollows and processes, especially at its middle, lateral, and back parts. Nearly in the middle of the base is fixed the body of the sphenoidal bone, with a considerable depression, surrounded by three remarkable processes. On each side of these there are two deep hollows, formed by the broad processes of the same bone, and immediately behind its middle is a considerable declivity leading to the large hole in the occipital bone. On each side of this lie the petrous portions of the temporal bones, with numerous furrows, depressions, and holes in their neighbourhood. The back part of the occipital bone is marked by two considerable prominent ridges, crossing each other in the middle, and forming four hollows, in which are lodged parts of the brain. From the upper internal process of the ethmoidal bone, there is either a ridge or furrow extending along the middle of the upper part of the skull, backwards and downwards, till it meets the crucial ridge of the occipital bone, the whole serving as attachment to a strong membrane that lines the skull and envelopes the brain.

Bones of the face.—The face is composed of fourteen bones, besides the teeth; these are generally divided into the upper jaw, containing thirteen bones, all articulated immoveably together, and the lower jaw moveable on the former. The thirteen bones composing the upper jaw are:

Two nasal bones of an oblong irregularly four-sided figure, convex on the outside and concave within, forming the upper part or bridge of the nose;

Two ungual bones of a rounded form and very thin substance, situated on the internal or nasal sides of the orbits,

Two malar or cheek bones, of an irregular, foursided form, with four remarkable angles, and a concave arch above, forming the external or temporal, and part of the lower edge of the orbits, their body constituting the well known bony projection of the cheeks;

Two superior maxillary bones, forming the principal part of the upper part of the upper jaws, the sides and floor of the nostrils, the sockets of the upper teeth, and the greatest part of the palate or roof of the mouth, and each having within its substance a large cavity or sinus communicating with the nostrils;

Two palate bones, making up the back part of the palate, with two concave arches towards the throat, two long irregular perpendicular processes extending upwards towards the orbits, of the floor of which they form a part, and a middle ridge between these, where the two are united to each other;

Two inferior spongy bones withinside the nostrils, where they are connected with the ethmoidal, superior maxillary, palate, and ungual bones; and the

Vomer, extending between the middle ridge of the sphenoidal and the junction of the palate bones within the nose like a plate, so as to form the greater part of the bony partition between the nostrils.

The lower jaw bone resembles the capital letter U, with its extremities turned at an obtuse angle upwards and backwards; it is narrowest at the chin, and its branches gradually diverge to the angle, where its sides rise into two remarkable processes, one backward, terminating in a rounded flattened head, articulating with the temporal bone before the zygomatic process, and the other pointed with a deep furrow within, for the attachment of one of the strong muscles by which the lower jaw is raised and pressed against the upper. The substance of the body of this bone is hollowed into two canals, communicating by holes with the back of the mouth, and externally with the sides of the chin. In its upper edge are formed the sockets of the lower teeth.

Facial angle.—In comparing the skulls of different animals, it is of consequence to attend to what is called the *facial angle*, which is formed by two imaginary lines supposed to be drawn, the one horizontally, in a direction parallel to the floor of the nostrils, and the other upwards, touching the inferior margin of the upper sockets of the teeth and the most projecting fore-part of the skull. This angle is greatest in the human subject, especially in a well formed European, and in those quadrupeds which most nearly resemble man, as apes; becoming gradually more acute as we proceed downward in the scale of animals to *cetacea*, *birds*, *reptiles*, *and fishes*.

Varieties of form, &c.—The skulls of different animals vary considerably in their general appearance, composition, and proportion, between the cranium and the face. In a few instances, as in the ourang-outang and the elephant, the vertical diameter of the head is at least equal to its horizontal diameter; but in most cases the reverse is found to prevail. The head is roundest in quadrupeds, birds, and most reptiles and longest in some of the *cetacea*, most fishes, and in crocodiles among reptiles.

The proportion between the cranium and face is extremely various, though it generally observes a pretty regular gradation as we descend from man to fishes. In the human subject the cranium is about four times as large as the face; in apes and monkeys more than twice as large; in baboons, and most beasts of prey, the proportion is nearly equal. In the ruminating quadrupeds, again, the face is double the cranium; in the hippopotamus, or river horse, the latter is three times as large as the former; and in the horse it is four times as large. In some of the cetaceous animals the outline of the cranium is very large, in proportion to that of the face. In birds, again, in reptiles, and in fishes, the area of the face is many times greater than that of the cranium.

With respect to the number of bones composing the head, this does not differ so much as might have been expected. The cranium of quadrupeds is generally composed of the same number of pieces as that of man, though, in some instances, the frontal, or sphenoidal bones are divided into two, and in others the parietal bones are closely cemented together. In the elephant, all the principal bones of the cranium are consolidated into one uniform long shell. In the cetacea, the parietal, occipital, and temporal bones are united.

There is a remarkable difference between man and quadrupeds, in the situation of the great occipital hole. In man this hole is almost in the middle of the base of the skull, and in nearly a horizontal position. In apes, especially the ourang-outang, which sometimes imitates man in his erect posture, this hole is situated a little farther back; while in the lower qnadrupeds it is still nearer the back of the head, and is so placed as to form a considerable angle with the horizon.

The trunk.—The bones of the trunk are arranged by anatomists under three divisions; the *spine*, or vertebral column, the *pelvis* or basin, and the *thorax* or chest; and this division, with the exception of the pelvis, holds in all the classes of vertebral animals.

Vertebræ.—The spine consists of numerous pieces, called *vertebræ*, which are divided into those of the neck, back, and loins. Each vertebra, except the one next the head, which is little more than a bony ring, with two depressions for receiving the condyles of the occipital bone, is divided into a body, a process extending backwards, and generally more or less pointed, called *spinous* process; one extending on each side outwards, called *transverse* processes; and two on each side, one above and one below, with articulating surfaces, having an oblique direction, and therefore called *oblique* processes. The body of the vertebra is more or less of a rounded form, with a smooth, flat, or rather concave surface, next the spinous process, where there is a considerable hole, and having two flattish surfaces for its articulation to the contiguous vertebræ.

The vertebræ of the neck, which, in the human subject, are seven in number, are distinguished from the rest by having a circular hole through each of their transverse processes. Their bodies are also smaller, and the great hole proportionally larger. The second of them has a process standing perpendicularly from the body, shaped somewhat like a blunt tooth, and resting against the inner fore-part of the vertebra above, which is articulated with the head, and turns round to a certain extent upon the second vertebra. The first cervical vertebra is called *atlas*, as supporting the head.

The vertebræ of the back differ from the rest in having their bodies very convex, the spinous processes long, pointed, and sloping downwards, and lateral depressions on each side for the articulation of the ribs. In man, they are twelve in number.

The vertebræ of the loins are distinguished by the spinous processes, which are strong, blunt, and horizontal, and by the want of lateral articulating surfaces. Their number in man is five.

All these vertebræ are united to each other in two ways. Between their bodies there is interposed a ligamento-cartilaginous substance, which, from its elasticity, enables the bones to move freely on each other, and by their oblique processes they are so articulated, and, as it were, wedged among each other, while their connexion is strengthened by numerous ligaments and muscles, as not easily to suffer dislocation. When united, the large holes between the bodies and spinous processes form a long continuous canal, which, in the recent body, is lined with a strong membrane, and contains that part of the nervous system commonly called the spinal marrow. Besides the lateral holes in the *cervical* vertebræ, through which important blood-vessels pass to the inside of the head, there are numerous orifices between the vertebræ for the passage of blood-vessels and nerves. The vertebral column does not form one straight line, but is variously bent in different parts. That part of the neck next the head retires a little backwards, while the rest of the neck advances forwards. The dorsal vertebræ form a curve, with its convexity next the back, and in the lumbar vertebræ the convexity is carried forwards. These various inflections answer several good purposes. Besides assisting in enlarging the cavities on the one hand, and supporting their contents on the other, they have considerable effect in balancing the several parts of the body, and regulating the centre of gravity.

Varieties.—The comparative differences in the vertebral column respect the number of pieces of which it is composed, and the greater or less complication of their structure. It is remarkable that almost all quadrupeds agree with man in having seven cervical vertebræ. The long-necked giraffe and camel have no more than the mole or the mouse. One exception only is known, the three-toed sloth, which is said to have nine cervical vertebræ. The number of *dorsal* vertebræ, again, differs in the various tribes, according to the number of ribs. Some of the apes and lemurs have fourteen, one species of ant-eater sixteen, the horse eighteen, the elephant nineteen, and the two-toed sloth twenty-three. In the cetaceous animals the number of cervical vertebræ may be considered as seven, though many of them are so cemented or united together as to form but one piece.

Birds differ from other vertebral animals in the number and composition of the vertebræ. In general they have more cervical vertebræ than other animals, the number varying from ten to twenty-three, and they are articulated by cylindrical eminences, so as to admit of free and extensive motion. The dorsal vertebræ, which vary in number from seven to eleven, are so cemented together as to be immoveable, and the rest of the spine forms another consolidated immoveable piece of bone.

In some reptiles, as turtles and tortoises, the vertebræ of the back are cemented together, and united to the upper shell; but in the other orders they are distinct. In serpents the number of vertebræ is very considerable.

In some fishes the number of pieces in the vertebral column is very great. Thus, for instance, the eel has more than a hundred vertebræ, and some sharks have above two hundred. In both these last classes the structure of the vertebræ is very simple, and their processes either very few, or extremely minute.

Pelvis.—The pelvis is situated at the lower extremity of the spine, and is composed of four principal bones, two forming a continuation of the vertebral column, called *sacrum* and *coccyx*, and one on each side, large and irregular, which has no proper name for the whole, though its several parts have been distinguished by particular appellations.

The sacrum in man is a large triangular bone, broadest at its upper part, where it is firmly united to the last vertebræ of the loins, convex behind and bending forward below, so as to form a concavity on its anterior surface. It bears the marks of having, in the fœtal state, consisted of five separate bones, now cemented together. At its upper, or large extremity, is the termination of the vertebral canal, and through its substance are formed four pairs of holes, for the passage of nerves and blood-vessels. On its back part are spinous processes.

The coccyx, or rump-bone, is small and triangular, and is articulated with the sacrum, which it resembles in its general structure and original conformation.

The side bones of the pelvis are each composed of three parts, one broad and flat, called *ilium*, or haunch-bone, convex externally, concave within, with a thick rough margin, and ending below in a hollow that forms part of a considerable cavity for lodging the head of the thigh bone; a second, called *ischium*, or hip-bone, forming the lowest part of the pelvis, of an irregular arched form, convex on its lower edge, and rising upwards to form another part of the great cavity; and a third stretching from the lower part of the *ilium* in front. and, meeting its fellow on the opposite side, so as to form a strong bony arch in front of the pelvis, called *pubes*, or share-bone. Where this last joins the ilium it is very thick, and helps to form the large cavity, or *acetabulum*, for the articulation of the thigh-bone. Between the share-bone and the ischium, on each side, there is formed a large hole called *thyroid*, which, in the recent subject, is nearly closed by a strong ligamentous membrane. The whole pelvis taken together forms a large opening, or cavity.

The comparative anatomy of the pelvis shews us that in no animal, except man, has it that hollow basin-like appearance. Its parts are proportionally smaller and more elongated in quadrupeds than in man, and some of those animals have the pelvis open in front. Cetaceous animals have no pelvis, but only a pair of small bones, resembling the pubes, next the tail. The coccyx is much longer in most quadrupeds than in man, forming, in fact, the bony part of the tail.

The pelvis of birds is most perfect in the ostrich, as in most of them the two side bones are at a considerable distance from each other. In these animals there is a coccyx, composed of from seven to nine pieces, to support the tail.

The pelvis of most reptiles is very small, and generally very imperfect, serving, in most instances, merely for the articulation of the hind legs. Fishes have no pelvis.

Bones of the chest.—The *thorax*, or chest, in man is composed of the twelve dorsal vertebræ already described, twelve ribs on each side, and the *sternum*, or breast bone.

The ribs are not all of equal size, the middle ones being the longest and roundest. They are all more or less arched, so as to form a considerable convexity externally, and a corresponding concavity within. They are flattened on their convex surface, especially towards the breast-bone, and the upper edge is rounder than the lower, in which latter there is a groove internally for lodging nerves and blood-vessels. Seven of these ribs are called true, and are articulated with the breast-bone, through the medium of long flat cartilages, whose length increases as the ribs descend; and the other five are termed false ribs, because the cartilages attached to them do not reach the breast bone. All the ribs are fixed each between two vertebræ, by an articulating head, and a flattened tubercle beyond the head, admitting of considerable motion upwards and downwards, and thus enlarging or contracting the cavity of the chest.

The sternum, or breast-bone, of the human subject, is generally composed of three parts; one next the neck, nearly resembling a heart, with the upper part very thick and notched in the middle; a second, long, thin, and narrow, compared with the former; and a third, smaller than the other two, generally more or less pointed at its extremity, and somewhat cartilaginous, hence called the *ensiform cartilage*. Along each side of the sternum are seven holes for the insertion of the true ribs, and on each side of the heart-shaped portion there is a cavity for the articulation of the collar-bones.

The thorax of quadrupeds is generally longer, narrower from side to side, and deeper from back to breast, than in man; the sternum is longer and narrower, and composed of more pieces; and the ribs are straighter and generally more numerous, following the proportion of the dorsal vertebræ. Among these animals, however, bats and armadillos have only eleven pairs of ribs.

The thorax of birds has several peculiarities. The ribs are few in number, perhaps never exceeding ten pairs; and the sternum, besides being broader and thinner, has a remarkable broad, thin, and sharp process, extending perpendicularly from its middle, thus allowing large and deep spaces for the attachment of those strong muscles which move the wings.

Some reptiles have a very large and extensive sternum, as turtles and tortoises, when the office of that bone is supplied by the lower shell or breastplate, and the crocodile, which, besides the ordinary sternum, has an additional bony plate, extending from the thorax to the pelvis. Some of them, as the salamander, have ribs but no sternum, while others, as the frog, have a sternum but no ribs. In many, as the lizards and chameleons, the ribs are very numerous. This is also the case with serpents, which have a prodigous number of ribs, but no sternum. In fishes the structure of the thorax is similar to that of serpents, except that in some the ribs are not connected with the vertebræ, and in the cartilaginous fishes there are no proper ribs at all.

For the sake of general application in comparative anatomy, we shall, with Dr Barclay, divide the extremities into *atlantal* and *sacral*, the former being those next the head, the latter those at the opposite end of the body.

The atlantal extremities in man consist of the *scapula*, or blade-bone; the *clavicle*, or collar-bone; the *humerus*, or shoulder-bone; the *radius* and *ulna*, or bones of the fore-arm; eight bones of the carpus or wrist; five *metacarpal* bones in the palm of the hand; two *phalanxes*, or joints of the thumb, and three of each of the fingers.

The blade-bone, is that broad triangular bone which is situated on the back, covering the upper ribs, being broadest at its upper or atlantal edge, and becoming gradually narrower towards its lower or sacral points; its longest side next the vertebræ is called the base. On the side next the ribs it is concave, and convex on the other side; and across this convex part. near the top, extends a perpendicular process, called the spine, which separates the convex part of the bone into two unequal portions. The spine terminates in a broad flat process called *acromion*, and near this there proceeds from the body of the bone a crooked pointed process, called coracoid. Between these, and a little lower, the bone is very thick, and forms a broad superficial cavity for the articulation of the shoulder-bone.

The collar-bone is long and round, and has nearly the form of the long italic letter *ſ*. It extends between the acromion process of the blade-bone, to which it is united by a broad flat extremity, and the heart-shaped part of the breast-bone, where it retains its cylindrical form. The chief use of this bone is to keep the blade-bone and arm in a proper position, and regulate their motions.

The humerus is long, cylindrical, a little twisted, and, like all the other long bones, smallest in the middle. Next the scapula, it terminates in a large round smooth head, situated a little obliquely with respect to the body of the bone, and surrounded by a rough furrow, and on the outside, near the head, is a considerable tubercle; at the other extremity, where the bone becomes broader, there are several processes, particularly two condyles, and a smooth part between them, which, in the motions of the elbow, performs the office of a pully. From the upper and fore part of the bone, near the large tubercle, there is formed a remarkable groove for lodging the tendon of one of the large muscles of the arm.

Of the two bones of the fore-arm the *ulna* is the largest at the extremity next the *humerus*, where it forms the elbow, by a process projecting backwards, and a hollow for receiving the pulley of the *humerus*. Hence it passes in a direction a little curved, tapering towards the wrist, where it terminates, on the side next the little finger, in a roundish head and a small projecting point.

The radius is smallest next the humerus, with which it is articulated by a round head, and with the side of the ulna by a lateral tubercle; hence it passes to the wrist, growing a little larger as it proceeds, and is articulated by a considerably irregular surface to the bones on the side of the hand next the thumb. Between the radius and ulna passes a strong ligament called *interosseous*, which strengthens the connection of the bones, regulates their motions, and assists in giving attachment to muscles.

The bones of the carpus, or wrist, are eight in number, and are placed in two rows; three of them, viz. the *scaphoid, lunar*, and *cuneiform*, being articulated with the radius and ulna, and five others, called *pisiform, trapezium, trapezoid*, the *large bone*, and the *unciform*, or hook-like bone, connected on one side with the three bones just mentioned, and on the other with the metacarpal bones.

The metacarpal bones constitute the frame-work of the palm of the hand. They are long, terminate at each extremity in a head, are flattened next the inside of the palm, and rounded next the back of the hand. One belonging to the thumb, has a freer articulation than the rest, and is therefore moveable in more directions.

The phalanxes, or bones of the fingers, resemble the metacarpal bones, except that they are shorter and more cylindrical. Those forming the tips of the fingers and thumb are the shortest and flattest, and have a rough surface near their extremities. The articulation of all these bones forms a simple superficial hinge, except where the bones of the fingers join the metacarpal bones, where the articulation is more free and the motion less confined.

Almost all the vertebral animals, except serpents, possess atlantal extremities. In quadrupeds and reptiles they constitute the fore legs, except that in bats and flying squirrels, among the former, and in the flying dragons of the latter class, they perform the office rather of wings than legs; in cetaceous animals they form the swimming paws, or, as they are improperly termed, the *pectoral fins;* in birds, they are the wings; and in fishes they support the real pectoral fins.

All quadrupeds, cetaceous animals, birds, and most reptiles, have a *scapula;* and in fishes there is a bone supporting the bones of the pectoral fin, which resembles a scapula in office, if not in figure.

A considerable number of quadrupeds have no clavicle, though it is by no means confined to apes, lemurs, and bats, or the order denominated by Linné *primates*. It is found in all those quadrupeds that make much use of their fore-legs; either for holding objects, as the squirrel and beaver; for climbing, as the sloth; for digging and raking the ground, as the mole, the ant-eater, and the hedgehog. Some other quadrupeds, as the *feræ* and some *glires*, have a small bone analogous to a clavicle, but not immediately articulated with the other bones. Cetaceous animals have no clavicle.

There is a peculiarity of structure in birds which deserves particular attention. The bone in poultry, which, in the vulgar language of the table, is called *hug-me-close*, really consists of two bones, the scapula, which lies horizontally and nearly parallel to the vertebræ, and is flat, and more or less broad, and the clavicle, which is cylindrical, and passes down at a considerable angle with the scapula to be articulated with the breast-bone. Besides these, there is a fork-like bone, commonly called the *merry-*

thought, having its angular point articulated with the most prominent part of the keel of the breast-bone, and the ends of its two branches join to the clavicle and scapula where these are united. By this mechanism, the wings are kept from approaching too near each other in the rapid motions of flying, while the whole articulation of the atlantal extremities is strengthened.

Many reptiles have a clavicle, which, in tortoises, is articulated with the humerus. No clavicle is found in fishes.

The humerus forms an essential part of the atlantal extremity in all the vertebral animals that have articulated members; but it is generally shorter, proportionally stronger, and more crooked than in man.

The radius and ulna are likewise very generally found in all these animals, though the former is wanting in the bat; and, in some cases, the two bones are closely united. In some reptiles, too, they form but a single bone, divided at each extremity into two conical pieces. They are not found in fishes.

Carpal and metacarpal bones are found in quadrupeds, cetaceous animals, birds, and reptiles, but vary considerably in their structure and proportion. In most quadrupeds the metacarpal bones are extremely long, forming what is called the leg. In cetaceous animals, again, these bones are short and thick. In birds there are two carpal and two metacarpal bones, of which the latter are consolidated together.

Several animals, both quadrupeds and reptiles, and some cetacea, resemble man very nearly in the structure of the fore-paw. This is particularly the case with the primates in the first class, and the porpoise in the last. In many quadrupeds, however, the number of toes is small, often two, and in some instances only one; and very few have what may be properly termed a thumb.

The sacral extremity in man is composed of the thigh-bone, the *patella* or knee-pan, two bones of the leg called *tibia* and *fibula*, seven bones of the *tarsus* or instep, five of the metatarsus, and fourteen of the toes.

The thigh-bone is the longest and strongest of the human body. It is articulated with the pelvis by a large spherical head set to the body of the bone by a long cylindrical neck, at the base of which there are two protuberances called the greater and less *trochanters*. The bone becomes broader and flatter as it passes to the knee, where it terminates in two very prominent condyles and a middle pulley.

The patella, rotula, or knee-pan, is of a rounded triangular form, narrowest next the leg, convex externally, and concave and very smooth internally, where it covers the knee. It is not firmly connected with the thigh-bone, but is loosely articulated, through the medium of strong tendons and a ligament.

The tibia forms the principal bone of the leg. It is not cylindrical, having a sharp ridge in front, constituting what is called the shin. It is largest at the end which joins the thigh-bone, where there are two superficial cavities divided by a double prominent ridge for receiving the condyles of that bone. It again grows large at the instep, where it terminates in two protuberances, of which the larger forms the inner ancle.

The fibula is a long slender bone, of nearly equal size throughout its whole extent, except that its two extremities are a little enlarged. It passes down on the outside of the *tibia*, has a small head, with a superficial cavity on one side by which it is connected with the upper side of the tibia, and terminates below in an oblong flattened protuberance that forms the outer ancle.

The knee-joint, formed by the thigh-bone, tibia and patella, is a very curious piece of mechanism. The condyles of the thigh-bone do not rest immediately on the corresponding hollows of the tibia, but there is interposed between them on each side a flat cartilaginous substance of a semilunar form, and thickest at the edge, by which the pressure and friction of the one bone against the other are diminished. The articulation is greatly strengthened by strong lateral ligaments, and crucial ligaments behind; while the tendinous and ligamentous expansion attached to the patella gives additional strength to the fore-part of the joint, and the whole is secured by a firm and complicated capsular ligament.

The tarsus, or instep, is formed of the *heel-bone* projecting behind, the *astragalus*, supported on the heel-bone, and having a smooth round process for the articulation of the tibia, the *navicular* bone, joining the fore part of the astragalus on the inside next the great toe, the *cuboid bone*, connected on the other side with the fore part of the heel-bone, and three *cuneiform bones*, that form a separate row, for the articulation of the metatarsal bones.

Of the metatarsal bones, that which supports the great toe is the thickest and strongest. In general they resemble the bones of the metacarpus, except that they are proportionally larger, flatter on the sides, and the round heads by which they are articulated with the bones of the toes are smaller.

The phalanxes of the toes very nearly resemble those of the fingers, and are articulated in a similar manner.

The form of the human foot is admirably adapted both to support the great weight which it is required to sustain, and to facilitate the motions of walking and running, without allowing these motions to be so free and lax as to encounter the risk of frequent dislocation. The bones of the *tarsus* and *metatarsus* are so connected together as to form a very secure arch, the highest part of which is the astragalus, which forms a sort of keystone to the whole fabric, while the foot rests chiefly on the projecting part of the heel-bone and the distant extremities of the metatarsal bones, as on the buttresses of the main arch. The bones are so firmly connected together by articulating surfaces and surrounding ligaments as not easily to be displaced, while they allow such a degree of motion as to prevent too great a shock of the body in the various actions in which the feet are chiefly employed.

All quadrupeds have the sacral extremities; for though some of these animals, as seals and walrusses, appear to have no hind legs, they have bones connected with the pelvis perfectly analogous to the thigh-bone, &c. though they approach too near each other, and are thrown too far backwards to serve the purposes of feet. In a few instances, as in apes and bears, the form and proportion of the several parts of the sacral extremity nearly resemble those of man, except that the heel is raised more above the ground in walking. In the majority of quadrupeds, however, the thigh-bone is very short, and projects but little from the body. Many quadrupeds also want the fibula. Here we must notice a particular construction that prevails in the ruminating quadrupeds, and those of the horse tribe, both in the atlantal and sacral extremities. What is properly the knee in all these animals, that is, the conjunction of the thigh bone and tibia, is situated far up the limb, and is entirely hidden by flesh; but there is a long metacarpal or metatarsal bone, called in veterinary anatomy the *cannon*, and the carpus is improperly termed the knee. From the distant extremity of the *cannon* commences the foot, consisting, as in man, of three phalanxes, called in the horse the *great pastern*, the *little pastern*, and the *coffin bone*. Thus these animals rest on the point of the toes.

There are no sacral extremities in cetaceous animals. In birds they resemble those of man and quadrupeds, consisting of a moderately long cylindrical thigh-bone, a tibia, to which, in some instances, there is added a small slender fibula, closely adhering to the tibia, a single long metatarsal bone, articulated with the tibia, without the intervention of a tarsus, and generally either three or four toes. These toes are differently situated in different tribes. Some, as the ostrich and the plover, have them all pointing forward; a few, as woodpeckers, have two directed forwards, and two backwards; but, in most instances, three of them stand forwards and one backwards.

Almost all reptiles have sacral extremities when arrived at their perfect state, one of the most remarkable exceptions to this rule being the *siren*. In their general structure they resemble those of quadrupeds.

Fishes cannot be said to have sacral extremities, though their abdominal fins have sometimes been represented as analogous to those organs.

We have now noticed all the bones of the skeleton, except one attached to the tongue, which we shall mention when describing that organ, some small bones, constituting a part of the internal organ of hearing, to be noticed under Sensation, and the teeth, which will be considered under the head of Mastication. In reckoning up all the bones that compose the human skeleton, we find them to amount to about 240.

The proper moving organs of the animal body are the muscles. These are bundles or masses of fleshy fibres, of a red colour in the warm-blooded animals, and of a whitish colour in the cold-blooded. They are generally found next the surface of the body, covering the skeleton, but a few of them are within the principal cavities; and indeed there are but few of the soft organs of which muscular fibres do not form a part. A large and strong muscular expansion separates the chest from the belly, and the heart itself is principally a large hollow muscle. It is with the external muscles, however, which are attached to the bones, that we are now chiefly concerned.

The muscles are generally composed of two parts; one called the belly of the muscle, composed entirely or chiefly of fleshy fibres, collected together first into small bundles, and these again into larger, and arranged for the most part parallel to each other; the other a white glistening substance, similar to ligament, and called *tendon* or sinew, which sometimes terminates the muscle at one extremity, in a few instances at both, and is sometimes extended along one side, into which the bundles of fleshy fibres are inserted.

Most of the muscles are attached to bones, generally by both extremities, and as in many instances one of the bones is more moveable than the other, the attachment of the muscle to the less moveable bone is called its *origin*, and that to the more moveable bone its *insertion*.

In classing the muscles according to their real or supposed offices, those which bring two bones nearer together have been called *adductors*; those which draw them more apart *abductors;* those which bend a joint are denominated *flexors;* those which extend it *extensors;* and when two muscles, or two sets of muscles, act in opposition to each other, they are said to be *antagonists*.

Muscles have also received various names according to the direction of their component fibres. Thus, when the fibres run in a longitudinal direction they are called *straight muscles*, and when they run in an inclined direction the muscle is called *oblique*. In the latter case there is sometimes a middle tendon with fibres inserted obliquely into it on each side, forming what is called a *penniform* muscle; in a few cases there are two or three origins, and only one insertion, to a muscle. In this case it is said to have two or three heads, and is called *biceps* or *triceps*.

In enumerating the muscles of the human body, we shall adopt nearly the arrangement of Albinus dividing the body into regions, and noticing the principal offices of the muscles which are situated in each region, premising, that, as the body is divisible into two equal and similar halves, the muscles are enumerated in pairs, as they are generally situated on both sides of the body.

Two pairs occupy the skull, and serve chiefly to contract the skin that covers it; these are called *occipito-frontales* and *corrugatores supercilii.* Eight muscles occupy the space about each eye, and within each orbit, viz. one for closing the eye-lids, *orbicularis palpebrarum;* one for raising the upper eyelid, *levator palpebræ superioris;* and six for moving the eye-ball in various directions, *rectus attollens oculi, rectus deprimens oculi, rectus adducens oculi, rectus abducens oculi, obliquus superior oculi*, and *obliquus inferior oculi.* One pair is situated on the nose, and called *compressores narium*. Eleven pairs are situated about the ear, or within its internal cavity, viz. *attollentes aurem, anteriores auriculæ, retrahentes auriculam, tragici, antitragici, majores helicis, minores helicis, transversi auriculæ, externi mallei, tensores tympani, stapedii.* Eight pairs and one simple muscle form the fleshy part of the cheeks and lips, acting chiefly upon the latter, viz. *Levatores angulorum oris, levatores labii superioris alarumque nasi, depressores labii superioris alarumque nasi, depressores labii inferioris, depressores* *angulorum oris, zygomatici, buccinatores, levatores labii inferioris*, and *orbicularis oris*. Connected with the lower jaw more immediately are four pairs; two which draw it directly upwards, the *temporal* and *masseters*; and two which, acting separately, move it to a side, while together they assist the former, *pterygoidei externi* and *interni*. Connected also with the lower jaw, and generally drawing it downwards, are four pairs, *biventres maxillæ, mylo-hyodei, genio-hyodei*, and *genio-hyo-glossi*. Connected with the tongue and back of the mouth are ten pairs, and one single muscle, viz. *linguales, hyo-glossi, stylo-glossi, stylo hyoidei, stylo pharyngei, circumflexi palati mollis, levatores palati mollis, palati-pharyngei, constrictores pharyngis, constrictores isthmi faucium*, and *azygos uvulæ*; the three first pairs of which perform most of the motions of the tongue, while the rest assist in the act of swallowing. Eleven pairs are connected with the larynx, or top of the wind-pipe, and may be called muscles of the voice, though many of them assist in swallowing, viz. *Crico-thyroidei, crico-pharyngei, crico-arytenoidei, stylo-thyroidei, thyro-hyoidei, thyro-epiglottidei, thyro-arytenoidei, thyro-pharyngei, thyro-staphylini, arytenoidei, aryteno-epiglottidei.*

Seventeen pairs are situated about the neck, and more or less attached to the head, viz. *sterno-thyroidei, sterno-hyodei, latissimi colli, sterno-mastoidei, omo-hyoidei, coraco-hyoidei, longi colli, trachelo-mastoidei, splenii capitis, recti capitis interni, recti capitis lateralis, recti capitis postici majores* and *minores, complexi, obliqui capitis superiores* and *inferiores*, and *trapezii*. Of these the first five, when acting in pairs, draw the head downwards, while acting singly they turn the head to one side, and most of the rest turn the head round upon the neck. Many of them also assist in swallowing. The last of them, acting together, draw the head and bend the neck backwards.

Besides these there are twenty-two pairs or sets of muscular fibres on each side, covering the back of the neck, the back, breast, loins, and belly, which are not connected with the head or extremities, but serve to perform the principal motions of the spine, act upon the ribs in respiration, and form the walls of the belly. These are, *interspinales colli; spinales cervicis; intertransversarii colli; transversales cervicis; cervicales descendentes; multifidi spinae; semi-spinales dorsi; serrati postici, superiores* and *inferiores; scaleni; levatores costarum duarum; quadrati lumborum; sacro-lumbales; longissimi dorsi; psoae parvi; obliqui externi abdominis; obliqui interni abdominis; transversi abdominis; recti abdominis; triangulares sterni*, and *intercostales externi* and *interni*.

Five pairs, and one single set of fibres, are also found about what is called the perinæum, acting chiefly on the rectum and genital organs, viz. *coccygei; curvatores coccygis; levatores ani; sphincter ani; acceleratores urinae*, and *transversales perinaei*.

About forty-five pairs, and several sets of muscular fibres, are connected with the atlantal extremity, from the shoulder to the fingers. Of these five pairs act more immediately on the scapula, as the *subclavii, rhomboidei, levatores scapulae, serrati antici, serrati majores*; ten pairs are inserted into the humerus, which they move in every possible direction, according to their situation and the direction of their fibres; viz. *deltoidei, pectorales, supraspinati, infraspinati, teretes majores* and *minores, subscapulares, coraco-brachiales, tricipites*, and *latissimi dorsi*; eleven pairs are concerned chiefly in the motions of the fore-arm, bending or extending the elbow, rolling the radius, so as to place the hand in the prone position, or with the palm downwards, or in the supine position with the palm upwards, and occasionally they act upon the humerus and *carpus* or wrist, as the *bicipites brachii, brachiales interni, radiales externi, supinatores longi, ulnares externi, anconei, supinatores breves, ulnares interni, radiales interni, pronatores teretes*, and *pronatores quadrati*; and nineteen pairs are concerned in the various motions of the fingers, viz. *extensores communes digitorum, extensores majores pollicis, extensores minores pollicis, abductores longi pollicis, flexores longi pollicis, abductores breves pollicis, opponentes pollicis, flexores breves pollicis, adductores pollicis, sublimes profundi, palmares longi, palmares breves, indicatores, abductores indicum, extensores digitorum minimorum, abductores digitorum minimorum, flexores parvi digitorum minimorum, adductores metacarpi digitorum minimorum*; besides several bundles of muscular fibres, called *lumbricales* and *interossei*, lying in the palm of the hand, and partly between the metacarpal bones.

About forty-eight pairs or bundles of muscles are connected with the sacral extremity, reckoning from the pelvis to the toes. Of these, ten pairs lie chiefly in the region of the pelvis, and are attached to the thigh-bone, which they move in various directions, and, when that is fixed, assist in bending the body. These are, the *psoae magni, iliaci interni, glutei magni, medii* and *minores, pyriformes, gemini, obturatores interni, pectinei*, and *obturatores externi*. Fourteen pairs are seated chiefly on the thigh, and act partly on the knee-joint and partly on the thigh, or even the trunk of the body, viz. *quadrati femorum, bicepites crurum, semi-tendinosi, semi-membranosi, tensores vaginae femorum, recti crurum, sartorii, vasti externi* and *interni, crurales, adductores longi femorum, adductores breves femorum, adductores magni femorum*, and *graciles*. Twelve pairs lie chiefly on the leg, and act, some on the knee-joint, some on the foot or toes, and some occasionally on either, according as the one or the other may be more fixed. These are the *gemelli, solei*, (both forming the chief part of the calf of the leg) *plantares, poplitei, flexores longi digitorum pedis, tibiales postici, flexores longi pollicum pedum, peronei longi* and *breves, extensores longi digitorum pedum, peronei tertii, tibiales antici*, and *extensores proprii pollicum pedum*. The rest, amounting to eight pairs, and several independent bundles, are found about the foot and between the toes, of which they regulate the motions, viz. *extensores breves digitorum pedum, flexores breves digitorum pedum, abductores pollicum pedum, abductores digitorum minimorum pedum, flexores breves pollicum pedum, adductores pollicum pedum, transversi pedum, flexores breves digitorum minimorum pedum, lumbricales pedum*, and *interossei pedum*.

Thus it appears that there are above four hundred distinct muscles in the human body, of which the greater proportion is concerned in the motions of the head and face and the extremities.

The physiology of the muscular motions is of considerable importance; but we must here confine ourselves to general remarks. When a muscle acts, its fibres contract and are shortened. Hence the whole muscle swells, becomes broader and thicker, while its whole length is proportionally diminished, and it feels to the touch harder and tenser than in its natural state.

The shortening of muscles, by the contraction of their fibres, is in proportion as they are inserted more obliquely into the tendon. Hence we see the reason why most of the muscles of the human body are composed of oblique fibres, since a small contraction of the fibres may produce a considerable action of the whole muscle. Again, a muscle composed of opposite oblique fibres, or what is called a penniform muscle, acts with much greater force than one which has but a single row of oblique fibres.

All those muscles that are inserted into bones, are thus furnished with levers; and as in levers in general the action is different, according to the relative situation of the fulcrum, the power and the resistance, the same takes place in the muscular motions of the animal body. Thus, when the head moves backwards and forwards on the atlas, the fulcrum furnished by this bone lies between the resistance, that is, the weight of the head and the power, that is, the contracting muscles, as in what the writers on mechanics call a lever of the first kind. Again, when the heel is raised by the action of the muscles composing the calf of the leg, the resistance represented by the pressure of the *tibia* upon the *astragalus*, is between the power acting at the heel and the fulcrum at the toes, or the lever is of the second kind. Lastly, when we raise a weight held at the palm of the hand, by bending the elbow we use a lever of the third kind, in which the power exerted at the elbow is between the resistance at the palm of the hand and the fulcrum at the lower end of the *humerus*.

The motions of the bones, as produced by the muscles, are the combined effect of different forces, and hence a small number of muscles is capable of producing, with steadiness and accuracy, an almost infinite variety of motions by the various combinations in which they act. Thus we have seen, that only about forty-five muscles are required to produce the infinitely varied motions of the human arm and hand, by which so many ingenious arts are exercised, and such wonderful examples of mechanical genius are produced.

The contracting power of muscles is said to be owing to their irritability, or the capacity of being excited to action by an external stimulus. This property is supposed to be peculiar to muscular fibre, and continues to reside in the muscles of some animals for some time after the life of the animal is extinct. This is the reason why the parts of an eel, the heart of a frog, or the head of a tortoise, moves for some time after it is separated from the body; and hence the Galvanic influence throws the muscles of an animal newly killed into contraction.

In the comparative anatomy of the muscles, we may remark, in the first place, that the flesh of all warm-blooded animals is more or less red like that of man, and the general structure and position of the muscles are very similar in all these classes. There are some quadrupeds that have fewer muscles than man, but in the greater number there is a very important fleshy expansion, called the *subcutaneous muscle*, or fleshy panicle, which is attached to the skin, and serves to contract or wrinkle it when the animal wishes to shake off insects or crush them between the folds of his skin, The muscles of birds are said to possess less irritability than those of quadrupeds, and their tendons are often bony. Most reptiles, except those which have very long or prehensile tails, have fewer muscles in proportion to their size; but in serpents the muscles are extremely numerous. In both these classes the muscles are of a pale colour; but in most fishes they are white, are destitute of tendons, are proportionally larger than those of other animals, and are disposed in layers or flakes. In some of the crustacea, especially crabs and lobsters, there are very strong and large muscles, that move the claws and tail. Insects, though so full of motion, possess but few muscles, except in their *larva*, or caterpillar state, in which they are extremely numerous. In the mollusca, on the contrary, muscles are generally nnmerous, and in some instances very strong, particularly in the shell fish. The muscles of worms resemblo those of larvæ, or caterpillars.

There are some organs of motion found in the inferior animals different from those we have described in man. Thus, a great proportion of quadrupeds, all cetaceous animals, all birds in a greater or less degree, most reptiles, all serpents, and all fishes, have a tail which performs many important offices. In certain cases, as in some monkeys, in opossums, and in chameleons, it performs the office of a hand, and enables the animal to take a firmer hold on branches of trees, &c.; in all those animals that swim, it serves the purpose of an oar or a rudder, to impel them forward or regulate their course; in birds it has great effect in assisting and regulating their flight; and to almost all animals it becomes a useful defensive, and to many a very formidable offensive weapon.

Some quadrupeds, as the rhinoceros, the tapir, and more especially the elephant, have the snout prolonged into a proboscis, or trunk, which admirably supplies the place of hands in seizing objects and gathering their food.

In several of the mollusca there is a fleshy organ called the foot, which greatly assists the animals in their progressive motions, or in their endeavours to find a speedy retreat from danger.

Among the crustaceous animals and insects there are several peculiar organs of motion, of which we may particularise the large claws in crabs and lobsters. These are used not so much for progressive motion as to seize the animal's prey, and to break the hard shells in which it is commonly contained. Thus they serve the purpose both of hands and teeth, becoming at once organs of motion and of mastication. Similar organs are found in several insects, and many of these have a proboscis or trunk.

We are now to explain the progressive motions of animals, or the actions of walking, leaping, running, climbing, flying, and swimming; but we must, in the first place, make a few remarks on the attitude of standing.

To stand erect, whether on two legs or four, nothing more is required than to exert the extensor muscles of the legs, so as to preserve the equilibrium of the body. It is evident that quadrupeds have in this respect a great advantage over man, and more especially over birds; and hence we find the reason why the extensor muscles of the thigh are proportionally stronger than those of all other animals. Hence, too, we see why it is so difficult for dogs, bears, and some other animals, which are occasionally exhibited in the attitude of dancing, to support themselves long in that awkward and unnatural position. The long-necked birds would find it extremely difficult to support themselves in a standing position, especially on one foot, in which attitude they commonly sleep, were it not for a particular mechanism of the metatarsal bones, consisting of a particular eminence, which shuts into a socket at the end of the *tibia*, in such a manner as to oppose the flexion of the joint, and thus keep the limb in a steady position.

In standing on four feet, the atlantal extremities support the greater part of the weight of the body, as from the great weight of the head and neck in most quadrupeds, the centre of gravity is thrown forwards.
